July - Dec.
1864

July-Dec.
1864

LONDON:
PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,
171, FLEET STREET.

TO OUR READERS.

"WHEN I look through the Numbers of 1864 I am bold to say they are as good, or better, than their predecessors." This verdict of our Chaplain, "THE WILTSHIRE RECTOR," is sustained by more evidence than we need record; and it makes us pause to consider, as a guide for the future, why our pages in the Volume to which our present Address is prefixed deserve the gratifying praise.

One reason is very patent—our standard contributors have written as ably as heretofore, and many others, fresh and well-skilled, have enrolled themselves among our pensmen.

Another reason is also manifest. All the contributions have been based upon the sound practical knowledge of the respective writers. All have related to subjects of interest to one or more classes of our readers, and all have had for their aim the improvement of practice or the acquirement of truth.

A third reason is, that even in controversy a spirit of kindness and courtesy has been maintained. All seem to have been animated by the just conviction that an opponent has as much right to entertain an opinion as he has whom he opposes, and that he need not have his face scratched to make him feel that he is wrong.

May these characteristics which have earned for this Journal approbation and success in 1864 be maintained and intensified in 1865; and when this year's days are concluded, and our first Number of its successor appears, may it bear as its introduction an address as kindly-spirited and truthful from the same friendly heart.

INDEX.

ACER LOBELLII, 190
Achimenes — not flowering, 261; roots, preserving, 399; *Rollisonii*, 414
Acmena floribunda, 513
Aconite, Winter, culture, 269
Agapanthus umbellatus, culture, 15; potting, 280
Aglaoenema commutatum, 179
Agricultural Show, jottings at, 17
Agricultural Hall—*Poultry Show*, 96, 118, 138, 280; and the *Poultry Club*, 160, 180, 199
Ailanthus culture, lecture on, 432
Air-giving, 93
Alligator Pear, sowing, 279
Alocasia metallica and *Lovii* drying off, 380
Allspice, propagating Carolina, 220
Alpines in masses, 449
Alstroemeria culture, 328
Alyssum saxatile seedlings, 399
Amaranthus melancholicus ruber, 136
Amaryllis formosissima, is it hardy? 179; *longifolia* and *rosea* culture, 380
Ammoniacal liquor, use of, 95
Among the Welsh Mountains, 151
Amphiblemma cymosum, 291
Anæctocibilluses and their culture, 41
Anemone — culture, 327; *apennina* culture, 491
Annuals for garden decoration, 268
Ants—driving away, 35; to destroy, 110, 157; protecting wall fruit from, 173; trap, 276
Aphelandra Liboniana, 111
Aphides, destroying, 62, 158
Appetite, depraved, in fowls, 344
Apples as food for poultry, 142; for espaliers, 292, 316; dwarf, 338; sauce (New England), 344
Apricots—new, Royal de Luxembourg. De Jonghe's Sweet Kernel, 127; De Jonghe's Diamant, 128; bush, 157; in pots, 198; gum on, 517
Aquatics in pots, 198
Aquilegia cerulea, 414
Arabis lucida variegata, 276
Araucaria imbricata forming cones, 116
Arauja angustifolia, 513
Arbor Vitæ browned, 359
Artichokes — preserving, 137; winter dressing, 438
Asparagus — making beds, 35, 400, 415; covering in winter, 479; removing, 137; culture, 351; seaweed for, 400; forcing, 476; French culture of, 510
Asphalt path, 517
Aucuba japonica bearing berries, 405; sex of, 518
Auricula, Lord Clyde, 51
Aviary, mice in, 484
Azaleas—Souvenir de Prince Albert, 51; grafting, 56, 198; buds not expanding, 116; amena potted in loam, 440; shifting, 499; leaves falling, 518

BABIANA CULTURE, 328
Bacon — preserving, 464; Wiltshire, 526; earring, 526
Bantams — keeping small, 20; my Black, 160; Nankin, 206, 324; Black Game, 223; legs of, 324; buying, 266; legs and weight, 424; white, 504; weight of, 504
Bartonia nuda, 513
Battersea Park, 214

Bath and West of England Poultry Show, jottings on, 18; Turkeys at, 19
Bedding-plants, hardy, list and culture of, 81, 110, 137; propagating, 135; management, 432
Bedding for winter and spring, 365
"Bee-keeping," 321
Bee-book, is one wanted? 361; new, 422, 484
Bees—unhousing, price of honey, Ligurianising an apiary, 20, 39; supering, 20; artificial swarming, flowers, 38; in Australia, a "bee-bob," 39; ascertaining loss of queen, rules for purchasing, foul brood and dysentery, preventing swarming, outside a hive, queens, &c., 49; in Lincolnshire, 39; Ligurian swarms, Ligurians in Ayrshire, maiden swarms, uniting weak stocks; transferring, 60; in Perthsire, 79; queen worried, natural and artificial swarms, in supers, 80; transferring, aspect for, removing to the moors, times of swarming, existence of queen doubtful, 98; adding queens, at Royal Agricultural Society's Show, in Surrey, substituting boxes for straw hives, 99; Ligurian swarms, dying from confinement, duration of life, do not injure poultry, flowers for, 100; at Daventry, 106; preparation of wax, depriving stocks, 121; "A Devonshire Bee-keeper" in the *Times* "Bee-master," 140, 162; uniting voluntarily, commencing bee-keeping, purchasing stocks and hives, works on, 142, 319, 321, 351, 422; ill-success in bee-keeping, 162; forsaking a stock-hive; depriving, unions, good hives, 163, 164; autumnal removing, and transferring, 163; selection of queens, small swarms, 184; management and food, uniting, honey from combs not full, the season, foul brood, queens in 1862, 205; in Surrey, distance of flight, characteristics of Ligurian, borage-sowing for, 2, 6; working supers on common hives, stocks from condemned, comb-pruning, autumnal unions, robbing, transporting, 224; adding queens, foul brood, 225; Wildman at Dobney's Gardens, 226; comb-pruning, 244; ruin of a new stock, friend mistaken for an enemy, 245; are they omnivorous? treatment of weak swarm; honey dark-coloured, 246; managing on natural system, 263; foul brood in Yorkshire, 266; wasps and ivy blossoms; queen's excursions; comb plates, 283; at Whitworth show, causing swarm to settle, analysis of excreta, 284; management, 301; dark honey, food, Woodbury-hives; joining Ligurians to common; foul brood in Yorkshire, 302; foul brood, what written about it, 403; working hours; spider and wasp moth, 364; book on, 319; boxes and supers, 320; carnivorous; lecture on, 321; robbed by bees; earwigs in hives, from a distance, 324; uniting queens to, &c., variation in Ligurian, carnivorous, 342; foul brood, 343; winter feed-

BEES—Continued.
 ing, Woodbury and other hives, 344; Woodbury-hive, 361; are they carnivorous? uniting queen to; wasps eat, their management, 362; beginning keeping, feeding, 364; Ligurian degenerating, not carnivorous, 382; joining Ligurian to common, hive protectors, foul brood, times of swarming, 383; management in common hives, 493; rectifying irregular combs, variation in Ligurian, joining Ligurians to common, 404; workers short-lived, young reversed in cells, apiary in 1864, 420; taking honey from common hives, new bee-book, caution in operating with, rules for purchasing, 422; not carnivorous, stands for, 423; removing honey from hives, 424; swarming system, carefully feasted, 444; open driving, 463; death of a queen, 464; caution on mild weather, regicide, driving, new book on, breeding Ligurian, removing to a distance, 484; old comb, foul brood, 504; regicide among, 524; swarming v. depriving, 525
Beet culture, 211
Begonias, potting, 417; wintering, 417
Belfast Poultry Show, 58; Botanic Gardens, 133
Bignonia jasmoides not blooming, 158; radicans culture, 498
Bewley's, Mr., Rockville, Dublin, 102
Bindweed killing, 218
Birds—compromise with, 333; crop saved by, 370; protecting buds from, 511
Birmingham Rose Show, 27; Fruit, Chrysanthemum, and Root Shows, 451, 492, 510
Birmingham Poultry Show, 401, 411, 458; matters relative to, 303; Committee, censure on, 520; results, 524
Blindness in Cauliflowers, 16
Bloomsbury Flower Show, 69
Boiler—setting, 137; for stove, 457; without brickwork, 480, 495
Bolton Greys, 314
Bones, crushed, as manure, 493
Border, plants for a dry, 498
Botanic (Royal) Society's Show, 5, 25
Bottom heat—interrupted, 469; deficient, 318
Rougainvillea splendens, 179
Bouquets, artificial, 15
Bowling green, mending, 298; making, 338
Box tree, moving, 339
Brahma Poortra, 324, 400, 418, 442, 468, 480, 499; characteristics, 284; at Ilington Show, 299, 300; origin of, 360, 413; pullet staggering, 504
Bread, preventing bitterness in, 206
Briars, moving budded, 230
Brighton Horticultural Show, 254; Poultry Show, 483
Brussels Sprouts, gathering, 360
Bryn-y-Neuadd, 294
Bude-Haven Poultry Show, 118
Bulbs—forcing, 208, 247; culture, 227; for garden decoration, 268, 285, 327
Bromeliaceæ, notes on, 64
Butter, imported and exported, 60

CABBAGE—GROWING SEED, 35; CULTURE, 249, 277
Caladiums — in greenhouse, 261; wintering, 479
Calceolaria cuttings, 337, 378, 416
Calceolarias dying, 16, 191; in beds, 94; in exposed poor soil, 280
Calf, raising the, 384
Californian large trees, 237
Camellias — buds falling, 360; not opening, 499; grafting, 360; blooms falling, 441; in cocoa-nut fibre refuse, 457; thrips on leaves, 457
Camlin, 149
Campylobotrys regalis culture, 116; *refulgens*, 179
Canaries—disordered, 40; asthmatic, 464; dull and moulting, 526
Caponising, 266
Carhead, 128
Carnations—perpetual, 243; seaweed as a manure for, 498
Carpets, to clean, 40
Carrots—grubs, 137; crop failing, 441; trenching for, 478
Caterpillars, 296; on Cabbageworts, 315
Cattie, to prevent jumping, 383
Cattell's Nursery, 312
Cauliflower—blindness in, 16; culture, 33, 240, 296, 397; under glass, 515
Cayenne pepper, 197
Celeriy — blanching, 196; earthing up, 212; culture, 241, 258, 296
Cement to exclude air from bottles, 40
Centaura — *candidissima*, sowing, 198; wintering, 221, 279; propagating, 279; *argentea*, propagating, 243
Cereus hexagonus, grafting, 116
Chalk soil, evergreens for, 180
Charcoal-heated stoves, 457; fumes among plants, 467
Cherry — trees in pots, 14; De Jonghe's Transparent, 27
Chickens — decline in, 19; rearing, 36; v. green fly, 51, 86; mortality among, 58; pudding, recipe for, 159
Chicory for salads, 397
Chippingham Poultry Show, 432
Chiswick garden, 1; trial bedding plants at, 191
Chrysanthemums — stopping, 76; Show at the Agricultural Hall, 409; Birmingham, 409; Mr. Salter's 428; Mr. Forsyth's, 429; select list, 440; Bob, 493; children's show, 493; not flowering, 498; cuttings, 499; done blooming, 517
Churchyard, planting, 360
Cinerarias—seedlings, culture, 15; wanted to bloom, 279; leaves curling, 479; not blooming in large pots, 480; *maritima* propagating and wintering, 279
Cissus porphyrophyllus, 179
City gardening in New York, 105
Clay soil, improving, 95
Clematis—Townsend's seedling, 29; *Jackmanni*, 215; *rubro-violacea*, 291, 513
Clinanthus Dampieri seedlings, 6
Climbers—evergreen, 138; for house walls, 299; for conservatory, 440
Clover seed statistics, 35, 76
Cob-nut culture, 485
Cobaea scandens not flowering, 479

- Cochin-Chinas, 424; points in, 100; legs of, 246; Silver-Buffs, 301; cock, weight, 324; merits, 401; diarrhoea in, 526; at the Birmingham Show, 501; tail of Partridge cock, 504
- Cockatoos eating its feathers, 424
- Cocoa-nut fibre refuse for mulching, 229
- Colocynthe odoratissima, 111
- Coleus Verschaffeltii, wintering, 440, 467; Blumel and Verschaffeltii, wintering, 467
- Collingham Poultry Show, 402
- Coltsfoot, to eradicate, 158
- Compost-heaps, charred, fermenting, and turf, 315
- Conifers — fast-growing, 21; for sandy soil, 478
- Conservatory shading, 116; heating, 338; stage, 360
- Cooking-meats, 60
- Cookery again, 159
- Cooks, cookery, and Wilts bacon, 323, 423
- Coon bin, moth in, 20

GARDEN.

THE CHISWICK GARDEN OF THE ROYAL HORTICULTURAL SOCIETY.

ONDAY, the 27th of June, was a great day for the old garden at Chiswick; and no one came away from it without a feeling of regret and indignation at the neglect with which it is treated by

the present management of the Society. No one could walk amongst the ornamental trees now attained to a noble growth, and now showing fully the taste which dictated their arrangement, without expressing the anger that is felt for men who are lavishing thousands of pounds upon the gew-gaw garden at South Kensington, whilst upon these noble grounds at Chiswick the same management declared that the Society could not spare "ten pounds" more! The fact makes one pause in writing the words, and think a second time whether such a perversion can be, and that the horticultural Fellows do not gather together and resolve that such a perversion shall not be. It would be no idle resolve, be it remembered; but we believe that they hesitate, hoping that the management will take to a course more consistent with the objects of a Horticultural Society.

Among these objects is the increase of a knowledge of fruits and their cultivation—and at Chiswick the Society has to operate with the most complete collection of Apples, Pears, and Grape Vines that exists in Europe. Its noble viney and the excellence of the Vines within it are worth a day of railway travelling to inspect.

To be able to exhibit all this, and much more which we need not detail, was a triumph for the Chiswick Garden, for every one of the fifteen hundred who visited it that day felt how it towered above its disproportionately pampered competitor at Kensington. That number—1500 visitors—should speak with a trumpet tongue a lesson to the Society's managers. Of that number, 1360 were Fellows of the Society and their friends. Now, if this Strawberry Fête had been advertised as the fêtes at Kensington are always advertised, how many more hundreds of the public would probably have attended? Why was it not more publicly announced? Why was a less powerful band engaged than is engaged for the Kensington fêtes? If it was to obtain evidence that the Chiswick Garden is less attractive than the garden at Kensington, that intention was abortive, of which no better evidence is needed than the joyous groups assembled there compared with the formal, dressed-for-display throng at Kensington.

Quite sure are we that the Fellows who were at
No. 171.—VOL. VII., NEW SERIES.

Chiswick that day would record their votes, not only for more such assemblies there, but that the expenditure upon the garden shall be more liberal; that its turf and other parts of the ground shall be kept in good order worthy of what should be the model Society of Horticulture; and then those Fellows might be content to allow some of the glass structures to remain as they all are at present—mere propagating and nursing places for the plants to furnish the beds and borders at Ken-

MY ORCHARD-HOUSE.—No. 4.

A LEARNED friend who has written an extensive work on the Channel Islands, and who is an excellent authority on the matter, having resided in Guernsey for several years, in describing the climate of these islands represents them as being the "chosen battle field" for all the winds under heaven. The whole group lies in such a way off the main continent, that every fierce blast from the vast Atlantic Ocean meets a corresponding storm from the land, exactly at the spot where these favoured isles are placed.

Guernsey has, however, the distinction of a bad pre-eminence even here, while it frequently appears to me that our front walk, near which the orchard-house stands, is selected above all other spots in the island as that where furious storms most love to contend. On the 1st of January, 1861, about two-thirds of our orchard-house fell suddenly, as if a shell had exploded therein, under the violence of one of these gales, with a pressure of what seemed to me of about a hundredweight to the square foot! As no one would venture in, all the trees were crushed and the pots smashed, while the rafters fell among our Rose trees, levelling these at once. It was a sad sight for me, and it needed all my love for the work and conviction of its utility, even as a model and school for others around, to reorganise the house afresh.

A clerical brother quaintly reminded me, that "it was not a gin palace I was building, but a suggestive and useful structure." The house was accordingly rebuilt, the mutilated trees sprang up afresh, new plans were adopted, everything was on a better scale, and I have never regretted doing so.

When I think how many have profited by inspecting the work, and that I am able, I trust, to contribute something towards my brother amateurs by describing matters exactly as they are with me, it is impossible not to feel gratified. Orchard-houses seem especially adapted for amateur fruit-growers. More can be learnt in them in one year than in, perhaps, ten out of doors. And among other things it must not be forgotten, that time is to us all that which is most precious. Let us, then, be ever ready to contribute towards another's innocent pleasures, so few in this world; and let us shun all bitterness of expression, in gardening matters especially.

The continual strong breezes and generally cold weather of the last fortnight have been very trying to vegetation. Tender bedding plants, such as Amaranthus melancholicus

No. 823.—VOL. XXXII., OLD SERIES.

ruber, have been with us destroyed by the hundred. The wall Peaches look much injured; even standard hardy Pear trees have suffered, but under glass we have none of this, except that the season for gathering the fruit will not be so early as seemed likely during that wonderful May.

Peaches are colouring fast and are large. Apricots are ripe with us. De Milan, the earliest full-sized Apricot, was, however, ripe last year a week before this. The extreme heat of May obliged us to give much water to the roots, and, probably, they are somewhat chilled and the tree put back from this cause. I regret now that tepid water was not given, as it is a great object to forward these trees. Early Favourite Plum is ripe. Doyenné d'Eté Pear is about 2 inches in length.

Is it of any use to my brother amateurs to note the following? It seems to me that it would be very interesting for some northern amateurs to forward us southerners the sizes of the fruit in some of those decreed houses. Comparisons would not be odious in this case, for we must be at least ten days in advance in ripening power.

I have never before seen that best of early Peaches, Early York, so fine as at this date. Some fine specimens from half a dozen trees are nearly 6 inches in circumference, though Early York is but a medium-sized Peach. Something as early, as good, and full-sized would, indeed, be an acquisition. Canary comes near to it in excellence, it is a heavy cropper, of a lovely yellow, forming with Early York and Golden Purple, another rather late and singularly and beautifully-streaked Peach, such a triad as rejoices the amateur who has pleasure in colour. Early Crawford is about the size of Early York at present. Rivers's Orange Nectarine, of which we have some twelve trees, is $4\frac{1}{2}$ inches in diameter; Violette Hâtive about the same; Hunt's Tawny, a little larger; Downton, 5 inches in circumference. Chauvière, a very excellent bearer, and Stanwick, two of the very best Nectarines, are $5\frac{1}{2}$ inches; while Exquisite and Galande (French) Peaches are $6\frac{1}{2}$ inches in circumference. De Milan Apricot is $5\frac{1}{2}$ inches, and De Coulange 5 inches. The Peach Apricot and Kaisha are smaller. On these trees the crops are very heavy, about one hundred on one of them, and this makes them smaller this year.

It must be a mistake to try to grow quantity at the sacrifice of quality in orchard-houses, and wherever this is done the fault will soon show itself in the loss when sent to market, or in the next year's produce.

But I must resume the consideration of the other classes of Peach shoots. In the preceding paper we had discussed two classes and now arrive at a third, which is of rather a puzzling character. This class will be met with along the branches, more or less, at about their central portions of extension. They are slender, from 6 to 8 inches in length, and present the disagreeable phenomenon of an unusually large number of fruit-buds unaccompanied with leaves. There are, however, some very small buds visible near the bases of these slender shoots which are not fruit-buds, but they are dormant.

For summer pruning under glass we can dispose of this difficulty without much risk. If there is time to recognise the peculiar character of the shoot it would be proper to pinch to three leaves, instead of four at the first pinching-in, but it does not matter much.

Some pruners in the autumn, out of doors, would cut back to the small buds at the base of the shoot, having no expectation of fruit from them. Others would treat them as fruit-bearers, and cut-in to 4 inches for this purpose; but in the summer orchard-house pruning, which alone is now the question, it will be well to pinch-in a little more closely these shoots. By this means they will be closer to the branch (always a great object in a small space), and by the stimulating influence of the concentrated heat they may bear and grow too.

It seems unfair to expect the same slender shoot to bear fruit and to extend itself much. It is always better to have a certain number to select from. Some should bear, others should extend and ripen for the next season. Those which have borne their fruit should then be cut back below the spot where that fruit was grown, directly after it has been gathered in the autumn. The buds at the base will thus be stimulated by the sap being now directed to them. What they accumulate in the autumn is thus most precious for

the following spring. After a few seasons much becomes clear to the pleasing observer, and yet each succeeding year he will be reminded by mistakes and failures that gardening in its various branches is, indeed, an art, and he will be led to study the works of those scientific men who have done so much for him and his pleasures.—T. COLLINGS BRÉHAUT, *Richmond House, Guernsey.*

THE ROYAL HORTICULTURAL AND NATIONAL ROSE SHOW.

THIS was held at South Kensington on Wednesday and Thursday last, and never has it been our lot to see a finer display of old England's national emblem. Stand after stand, filled with the finest blooms from all the southern parts of England, and some from the north, extended in a close and in some places double line the whole length of the conservatory arcades, affording to the view a glorious display of the richest colours, and filling the air with a delicious perfume. The day being fair, though not so bright as one expects at the end of June, the attendance of visitors was very numerous, so much so as to render it almost an impossibility to get near the tables, especially where the nurserymen's collections were situated; and it was pleasing to observe the evident interest taken in the merits of the respective stands, and of the several varieties of which they were composed.

The first Class was for seventy-two kinds, one truss of each; a great improvement over the old and almost unmanageable Class of ninety-six. Here Messrs. Paul & Son were first with magnificent blooms, among which we particularly remarked Madame Charles Wood, Charles Lawson, Madame C. Craplet, General Washington, Lælia, John Hopper, Victor Verdier, Praire de Terre Noire, Hamlet, Olivier Delhomme, Lord Canning, Professor Koch, Prince Camille de Rohan, Gloire de Santenay, Gloire de Dijon, Narcisse, and Madame Eugène Verdier.

Mr. Cant, of Colchester, was second, and Mr. W. Paul third, the competition in the case of all three exhibitors being very close. Of Mr. Cant's, Monte Christo was noticeable on account of its blackish purple colour, Madame Cailat as a fine bright cerise, Maurice Bernardin for its fine colour, besides which there were fine examples of several of the kinds already named. Queen Victoria from Mr. W. Paul, white, slightly shaded with pink, and Princess of Wales, as a fine bright crimson, were remarkable for their beauty; to these must be added Charles Lefebvre, Beauty of Walham, and a host of better-known kinds. Mr. Mitchell, of Pilton Nurseries, Maresfield, was fourth; Mr. Keynes and Mr. Cranston also showing fine stands.

In Class 2, forty-eight kinds, three trusses of each, Mr. Turner was first with fine examples of Charles Lawson, La Reine, Queen Victoria, Louis XIV., Duchesse d'Orleans, Victor Verdier, La Ville de St. Denis, Senateur Vaisse, Anna de Diesbach, Gloire de Dijon, Souvenir de Malmaison, and others. Messrs. Paul & Son were second, Mr. Keynes third, and Mr. Cant fourth.

The next, Class 3, was for twenty-four kinds, three trusses of each, and in it Mr. Keynes took the first prize with beautiful blooms of Charles Lefebvre, Madame Furtado, Madame Charles Wood, La Brillante, Olivier Delhomme, Maréchal Vaillant, François Lacharme, John Standish, and Mademoiselle Bonnaire. Messrs. Paul & Son were second, Mr. Cant third, Mr. Turner and Mr. Fraser being fourth.

In Class 4, twenty-four kinds, single trusses, Mr. Turner was first, Mr. Keynes second, Mr. Cant third, and Mr. Fraser fourth. In the different stands were some excellent examples of Lælia, Madame C. Wood, Charles Lefebvre, Madame C. Craplet, Vicomtesse de Cazes. Madame Bravy, Clement Marot, and many others.

In the Amateurs' Classes, J. Hedge, Esq., of Reed Hall, Colchester, was first both in forty-eights and twenty-fours, showing, among others, fine trusses of Souvenir d'Elise Vardon, a splendid cream white; Rubens, white, shaded with rose; Comte de Paris, a superb white, all belonging to the Tea class; Madame Masson, Noisette Celine Forestier, Madame Boll, Charles Lawson, and L'Enfant Trouvé. Mr. Moffat, gardener to Viscount Maynard, Dunmow, was second for forty-eight, Mr. Ingle third, and Mr. Exell, gardener to

J. Hollingworth, Esq., was fourth. For twenty-fours, C. Worthington, Esq., Caversham Park, Reading, was second, Mr. Exell, third, and Mr. Ingle fourth.

For eighteen kinds, the Rev. V. Knox Child was first with a fine stand, Mr. Plester second, R. B. Postans, Esq., third, Dr. Cooper, Slough, fourth; and the Rev. H. Helyar, Pendermer Rectory, Yeovil, had an extra prize. All these exhibitions consisted of good blooms, and many of the trusses were very fine.

The Rev. V. Knox Child was again first in twelves; Mr. Churchfield, gardener to E. L. Charrington, Esq., Carshalton, second, and Dr. Cooper third.

Class 9 was for eighteen new Roses of 1863 and 1864. Mr. Keynes was first, Mr. Fraser second, Mr. W. Paul third, Messrs. Paul & Son fourth. Prominent among the kinds shown were Princess of Wales, Lord Macaulay, Lord Herbert, John Hopper, a fine violet purple seedling from Mr. Wm. Paul, Baron Adolphe de Rothschild, a fine fiery red, shown by all the competitors; Alba Rosa, white, with rose centre, the finest white Tea Rose which has appeared since Devonensis; Alfred de Rougemont, a large crimson purple; Le Baron Rothschild, carmine centre, shaded with violet towards the outside; and Le Rhône, rich vermillion. Madame Soupert, white, with flesh centre, also seemed a very desirable white Hybrid Perpetual; Emotion (Bourbon), white, more or less tinged with rosy pink, was very pretty in colour; and Louise Margotin, rose, was very desirable. Some beautiful blooms of this, from Mr. Fraser, were placed first in Class 10 for the best twelve trusses of any new kind of 1863, Mr. W. Paul taking the second prize with Lord Macaulay.

For twelve trusses of any kind, Mr. Keynes was first with Charles Lefebvre (magnificent), Messrs. Paul & Son second with Mrs. Rivers and Comtesse de Chabillant, Mr. Hedge fourth with the same kind, and Mr. Ingle third with Prince Léon. The first prize for the best twelve trusses of yellow Roses, not less than six kinds, was adjudged to Mr. Hedge. These consisted of Jaune de Smith, Celine Forestier, Aurora (very beautiful), Narcisse, Solfaterre, Triomphe de Rennes, Cloth of Gold, Louise de Savoie, Comtesse de Cazes, Isabella Gray (a beautiful deep yellow), and Enfant de Lyon. Messrs. Paul & Son and Mr. Cant took the remaining prizes in the order in which they are named.

Classes 13 and 14 were for Tea-scented and Noisette Roses, and the trusses exhibited comprised good examples of nearly all the best varieties, while the perfume they exhaled was delightful. Mr. Hedge was first, Mr. Worthington second, and Mr. Ingle third among Amateurs; Messrs. Paul & Son, Mr. Cant, and Mr. W. Paul holding the same relative positions in the Nurserymen's Class.

Class 15 was for single blooms of twelve distinct kinds, and here remarkably fine blooms were exhibited by Mr. Keynes and Mr. Turner, also by Mr. Cant and Mr. Hedge. Celine Forestier, Madame Furtado, Charles Lefebvre, Senator Vaisse, Madame C. Crapelet, Lelia, and La Reine may be particularised as a few of the finest, and Gloire de Dijon was magnificent.

A few competitors came forward for the prizes offered for decorated baskets or vases of Roses. By far the best came from Mr. W. Adcock, gardener to Mrs. Forbes, Petersfield, and from the simplicity of the materials employed it was particularly deserving of credit, as well as for the good taste, which avoided anything like overloading with flowers—a fault which was very apparent in the other designs. It was made something after the form of March's stands, the base being of moss, with a few Ferns and Grasses appearing to grow out of it; and the stem, which was, in fact, merely a crooked stick, was covered with moss, and supported a circular stand covered with moss, in which Roses were bedded (and not too many of them), a cluster of Rose-buds with the stalk and foliage forming the centre. Mr. Turner was second with a simple stand, in which Isolepis gracilis was employed with good effect; and Miss Wint third, with a basket supported by an imitation rough glass rock, with Ivy, Ferns, and Roses at its base, and beneath which was spread an anti-macassar, which would have been far better dispensed with.

Class 17 was for six bouquets of distinct kinds. Mr. Hedge was first with Comtesse de Chabillant, Senator Vaise, Madame Boll, Madame Bravy, Madame Vidot, and L'Enfant

Trouvé; Mr. Turner second; and Mr. W. Paul third. Madame Furtado and Praire de Terre Noire from the latter, were very fine, as indeed were the whole of those exhibited by the prizetakers.

Moss Roses, as shown, lost much of their principal attraction, the mossy covering being to a great extent hidden by the blooms. It is questionable whether they would not have been seen to greater advantage had they been shown in three trusses of a kind, and with an interval between each kind. Messrs. Paul & Son were first, Mr. W.-Paul second. The varieties were the Crested, White Bath, Baronne de Wassenaer, Gloire des Mosseux, Common, Nuits de Young, a dark purple, Julie de Mersent, and Lanei.

For the best three trusses of Hybrid Perpetuals Mr. Keynes was first, with immense trusses of Charles Lefebvre, the blooms measuring between 4 and 5 inches across, and the wonder of all who saw them. Mr. Cant was second with the same kind almost as large, and first for the best three trusses of Tea Roses with Souvenir d'Elise, Mr. W. Paul being second with Madame Villermoz.

In pot Roses Mr. Turner and Messrs. Paul were first and second, Mr. W. Paul third. Among them were Caroline de Sansal, a good summer pot Rose; President, fine; Gloire de Santenay, Souvenir de la Reine d'Angleterre, an effective autumn pot Rose; Lelia, La Reine, La Brillante, Gloire de Dijon, Modèle de Perfection, Orderic Vital, pretty in colour; Madame Furtado, &c.

For new Roses in pots Mr. W. Paul stood first, Messrs. Paul & Son second. Among those of the former, the best were Alphonse Damaizin, scarlet purple; Alba Rosa, one of the finest Tea Roses; Professor Koch, a very fine shaded crimson; Madame Caillat, with large smooth petals of great substance; Beauty of Waltham, Charles Lefebvre, Olivier Delhomme, fine colour, purplish red; François Lacharme, exquisite in form; and Emile Dulac, a fine lilac rose.

Messrs. Paul & Son, besides several of those already referred to, had La Brillante, very good; Maurice Bernardin, fine; Le Baron Rothschild, already noticed as one of the best of the new varieties; and Madame Wm. Paul.

Of miscellaneous objects some good wax flowers, of which the Roses were the best, came from Mrs. Mitchell, Wandsworth Road; Lilium auratum from Messrs. Veitch; plant cases from Messrs. Barr & Sugden; and, finally, a Cocoonut, ripened in the Duke of Northumberland's stove at Syon, for which a first-class certificate was awarded by the Fruit Committee. It will be recollected that this nut was set and began to swell under the management of Mr. John Smith, now Curator at Kew, and its maturation has taken place under the eye of Mr. Fairbairn, who is the present gardener.

FLORAL COMMITTEE, JUNE 29TH.—The great Rose Show was held on this day at the South Kensington Gardens. A Sub-Committee was summoned to inspect such new plants and florists' flowers as might be sent for examination, the introduction of which added much to the interest of the Exhibition.

Mr. Hally, Blackheath, sent several scarlet Pelargoniums. Enamel, a pleasing variety, pale rosy salmon trusses, with dark zone on bright green foliage, received a commendation; Red Riding Hood, distinct white eye, bright scarlet flowers, medium truss, broad zone on dark green foliage, very dwarf habit—second-class certificate; Queen Mab, too much resembling Adonis; and Goliath, a coarse-growing plant with variegated foliage.

Mr. Bull, Chelsea, sent a collection of scarlet Pelargoniums, impressing the Committee with the idea that they were all seedlings. A selection of the following sorts was made, but the Committee do not recognise them as seedlings, as the names of some of them appear in the catalogues of 1864:—Rosamond, pale salmon, new in shade of colour, zonate foliage, fine truss—second-class certificate; Madame Rendatler, deep rose, compact truss, fine form, slightly zonate—first-class certificate; Faust, fine truss of intensely deep scarlet flowers, zonate foliage—first-class certificate; Hector, deep rose, fine form—first-class certificate; No. 10 Psyche, pale salmon, centre shaded to white, small truss but fine petals, zonate foliage—second-class certificate. There were many other beautiful varieties in this mixed collection: Clipper, a fine flower, which received a first-class

certificate on a previous occasion; Achilles, a second at the last meeting; Persian, a delicate pale-shaded scarlet; Rose Rendatler, Eve, Fanny, &c. From Mr. Bull also came Canna nigricans—first-class certificate; Geonomia Ghiesbreghtii—first-class certificate. Mr. Bull sent also three seedling Mimulus.

From T. Laxton, Esq., Stamford, came Fuchsia Harlequin, pale pink corolla striped with purple, and Othello; neither of them were in any way novelties.

From Messrs. Downie, Laird, & Laing came Verbena Sir G. Musgrave, a dwarf-habited scarlet; truss average; flowers not first-rate in form; colour not equal to Lord Leigh and others of that class.

Mr. Wm. Paul exhibited several seedling Scarlet Pelargoniums of the Nosegay section, these seedlings being results of the perseverance of the late indefatigable and enthusiastic florist, Mr. D. Beaton. There is a decided novelty in their colour and style which will render them indispensable in every collection. They are but the first fruits of careful hybridising, and we may reasonably expect further progress. Some of these seedlings have much broader petals than the usual Nosegay section, such as Stella, Merrimac, &c.; but that by no means gives a coarseness to the truss, although it would almost constitute an intermediate position between the broad-petalled section and the Nosegays. Amy Hogg, light rosy purple, very large, fine truss standing well above the foliage, which is slightly zonate; this variety is quite new and distinct in colour; as a bedding plant it will be invaluable; it was the admiration of all who saw it—first-class certificate. Rebecca, rosy scarlet, broad petals, fine truss, distinct and new in colour; a most useful variety for bedding purposes—first-class certificate. Beauty of Waltham, darker shade of colour, fine flower, medium truss—second-class certificate. Glowworm, quite a novelty, with bright scarlet upper petals, the lower deep carmine. The trusses of this seedling were thin. If this plant can be grown stronger it will not be surpassed by any other Nosegay. Beaton's Indian Yellow: this, again, though quite novel in colour, in its present state did not produce sufficiently large and compact trusses, the essential qualification of this section of Pelargoniums. Orange Nosegay, had the same deficiency as the last two. Some of these seedlings will doubtless be exhibited again, when they may present an improved appearance. Mr. W. Paul also exhibited four seedling Roses:—Globosa (Hybrid Perpetual), a globular, compact, crimson red flower—second class certificate; Dr. Lindley, a shaded dark flower of very promising qualities; Princess of Wales, which has been much admired; and Robusta. The specimens exhibited were in bad condition to judge of their merits.

Mr. J. Walker, Thame, sent a collection of Sweet Williams called Auricula-eyed. They were very pretty, and received a special certificate.

Messrs. E. G. Henderson sent Variegated Scarlet Pelargonium Queen of the Nosegays; Petunia picturata, a white-striped variety, like many others; Petunia gigantea plena, a monster in size, large creamy white flowers faintly veined; Verbena Velvet Cushion, a most useful bedding variety, dwarf habit, dark rosy purple flowers, said to have been crossed with the old hardy garden variety venosa. The colour of this Verbena will be most telling in a mass, the foliage being very small.

From Messrs. Carter, Holborn, came Clarkia integrifolia flore pleno, a very beautiful and showy annual, not spoiled from its numerous petals forming what is called a double flower. It received a first-class certificate.

Mr. Townsend, Hornsey, sent three seedling plants of Clematis lanuginosa; but as there seemed some reason to believe that these seedlings had been before the Committee last year under different circumstances, they were consequently unnoticed until some further inquiry be made. All we can say is, they were strikingly like the seedlings exhibited by Mr. Jackman, of Woking, last year.

DOUBT AT THE LEEDS HORTICULTURAL SOCIETY.

A DISPUTE having arisen at our late Exhibition respecting a Vine that was exhibited as a "fruit tree in pot," for our satisfaction it was agreed to ask your opinion whether you

thought it eligible to compete in that class or not; and if the fruit being ripe it ought to have had the preference over a Peach tree in a pot with fruit unripe. Enclosed is our schedule.—R. F.

[The schedule has these two classes "LL. Fruit Tree in pot (bearing fruit). MM. Vine in pot (bearing fruit); and the classes are preceded by this general rule, "All fruits exhibited must be ripe and fit for table." We consider, therefore, that the Vine with ripe fruit was entitled to the prize, the Peaches being not ripe; and we consider a Vine in pot might be exhibited in Class LL., for it is a fruit tree. There should have been the words, "Grape Vines excepted," if the Committee intended to exclude them from that class. —Eds. J. of H.]

CRYSTAL PALACE ROSE SHOW.

The difficulty of reporting on a Rose Show with an attendance of 15,000 visitors and crinolines three deep before the boxes is a matter of no ordinary character, and I was unable until after the rush of visitors came in to get near the boxes in which the magnificent blooms contributed by our leading nurserymen were placed. When I did so the thought occurred to me, What good will it be to write down the names of ninety-six Roses? and for whose benefit will it be done? and might I not adopt some better plan for benefiting the lovers of the Rose than such a process implies? There are various classes of Rose-lovers and Rose-growers who frequent these shows or who wish to know about them. There are exhibitors who have an eye to the future, and who desire to know what Roses which they have not may be useful to add to their collection; similarity to other varieties out does not affect them provided they be good exhibition Roses. Now it is quite evident that if a Rose be a good one, a large grower and a large exhibitor will not be over-careful as to its similarity to another kind, it may be useful to him some day for making up his 96's or 48 trebles. Then, again, there is the small grower, who also desires to be an exhibitor. With him the selection must be more particular, for he cannot afford room for all, and of those sorts which are most like each other he must discard some, keeping one only out of the number. Then, the amateurs *pur et simple*, who have no ambition to excel as exhibitors, love a few Roses, and love them only for their own sake. With them colour and effect are more thought of than size and shape, and a brilliant fiery crimson is much more thought of than a delicate flower which to a florist is the perfection of shape and substance.

There are some Roses which meet all such classes, there are some which do not. Thus, take such a Rose as Charles Lefebvre. No one can do without it—however small the collection, it must be there; while, on the other hand, when you hear Turenne or E. Bourcier is a fine Rose when you can catch it, why, the amateur cannot want to catch it. He cannot afford to give it space, and only, perhaps, get one bloom on a plant. To a nurseryman this is a matter of no moment; space to him is comparatively a trifling matter compared to the chance of getting a fine bloom some day when he wants it very much.

Let us see how this applies in the Class of new Roses, in which Mr. Wm. Paul was first, Mr. Keynes second, and Messrs. Paul & Son third. There were in all these boxes Roses which without doubt are fine, but so like one another that amateurs would hardly care to fill their gardens with them all. Thus, Maurice Bernardin, Olivier Delhomme, Madame Boutin, Mad. Julie Daran, La Brillante, and others come at times so close to one another, that even an experienced Rose-grower will find great difficulty in determining the name of one of the flowers. Such a case did occur. One of our very best amateur growers had misplaced the name of one of his flowers, and brought it to one of our most successful and experienced Rose-growers in order to ascertain its name. He said, "It may be any of these, but I think it is so and so."

Of the Roses of 1861, sent out here in 1862, the following occurred in these stands, and have established beyond doubt their claim to be distinct, and will probably remain a long time on our lists. H.P. Charles Lefebvre (Lacharme), the finest crimson Rose we have, a fine grower, and of a

substance of petal quite wonderful; Due de Rohan (Leveque et fils), a noble flower of the Senateur Vaisse type, but of a somewhat lighter shade of colour; François Lacharme (Verdier et fils), brilliant carmine with a purplish shade, very globular flowers, and altogether a first-rate Rose; John Hopper (Ward), beautiful lilac rose with a rosy crimson centre, very fine, and of excellent habit; Madame Boutin (Jamin), beautiful well-formed Rose, of fine habit; Madame Caillat (E. Verdier), this Rose does not seem much known—it is not in Margottin's or Rivers's lists, but I have it very fine, and some blooms of it exhibited in the various stands were excellent—it is a bright Rose, well shaped, and very effective; Madame Charles Wood, a beautiful Rose, of large size, with large petals, and very lasting; Maréchal Vaillant (Leconte), rosy crimson, double, and well formed; Maurice Bernardin (Granger), rich crimson, at times very like others of the same style; Monte Christo (Fontaine), brilliant dark crimson, a fine and distinct Rose; Olivier Delhomme (Verdier et fils), brilliant crimson, good shape and outline—I have not found it a very vigorous grower, but it may be so; Prince Camille de Rohan (E. Verdier), a very distinct Rose, rich dark maroon crimson—some blooms looked a little too thin; Souvenir de Comte Cavour (Margottin), a beautifully brilliant dark Rose; Souvenir de Lady Eardley (Guillot père), a rich rosy purple Rose; Vicomte Vigier (Verdier et fils), splendid colour; Beauty of Waltham (Wm. Paul), light rosy crimson. There were other Roses of the same year in the various stands, such as Christian Püttner, Alphonse Damaizin, Emile Dulac, Madame Julie Daran, but I do not think them equal to others of the same style amongst those I have selected. And so with another Rose which it goes to my heart to say a word against for the name it bears—I mean Reynolds Hole; but although very bright and very pretty in Mr. Wm. Paul's stand, yet I fear it is too small for our present taste.

Amongst the Roses of 1862, let out here in the spring of 1863, the following were very noticeable, although I do not think that any of them were equal to Charles Lefebvre or François Lacharme; still they were very beautiful, and are Roses we must have:—Alfred de Rougemont, rich crimson purple, a very attractive colour; Baron Adolphe de Rothschild, brilliant red, approaching to Lord Clyde; Baron de Rothschild, a fine rose; Deuil de Prince Albert, dark crimson, but has the great defect of hanging its head when on the bush; Jean Goujon, light crimson—broad and flat Rose, one or two blooms of it were very bright; Le Rhône, rich colour, fine shape, but, I fear, likely to be delicate; Madame Freeman, pale flesh and white; Mrs. William Paul, red, shaded with dark crimson; President Lincoln, brilliant cherry rose; William Paul, dark crimson; André Leroy, large deep crimson; Laurent Descours, purplish crimson; Vainqueur de Goliath, a fine dark purplish crimson flower; Beauté Française, in Mr. Cant's stand, very like Léon des Combats, but brighter, I think; Paul Desgrand, bright red, shaded; M. Alfred de Rougemont, white, shaded with rose. I have not entered into detailed descriptions of these, for I think we hardly yet know which will stand the best; but I am inclined to think I have selected those which are most likely to be enduring.

The Roses of 1863, sent out here this spring, were not very numerously exhibited. Amongst them I noticed as good:—Alpaïde de Rotalier (Campy), clear satiny Rose, but flat in shape; Madame Derreux Douvillé, a beautiful Rose, to which I alluded last week—the flowers exhibited were small, but it will be a good and useful Rose—Paul Delameillaray, a very vigorous large-petaled Rose; Lord Herbert, bright crimson, very much like Beauty of Waltham; Lord Macaulay, a good dark; and Lord Clyde, a very splendid Rose.

Of new Bourbons let out during the same period, there were exhibited Louise Margottin (incorrectly placed in some lists amongst the H.P.'s), a very pretty rose-coloured flower, of good shape; Emotion, somewhat similar in shape but paler in colour; Mademoiselle Emain, another light-coloured and pretty flower; and Reverend H. Dombrain, a beautifully-shaped and high-coloured Rose, as exhibited not quite so full as I have seen it, especially on the old plants at Margottin's, where it was very fine.

Of new Teas there were shown Rubens, a fine white, shaded; Triomphe de Guillot fils, white, shaded with rose

and salmon, and in one instance exhibited with a great deal of coppery bronze shading, which gave it a very striking appearance; and Alba, or Alba rosea, a magnificent new Rose, somewhat in the style of Madame Bravy, light, almost white, with rosy centre.

It were an almost endless task to enumerate the various Roses exhibited in the stands of both nurserymen and amateurs. In the former the first prizes were, as it will have been seen, very much distributed, having been respectively assigned to Messrs. Paul & Son, Mr. Cant, Mr. Turner, and Mr. Keynes (two). The second prizes went to Mr. Mitchell (Piltdown), Messrs. Paul & Son, and Mr. Turner (two). Not so amongst amateurs. Here all the first prizes were taken by Mr. Hedge, whose Roses equalled, if not surpassed, his former productions, and whose Teas were a marvel of fine growth and care. And here I may be excused for one word touching a personal matter. My name appears as a prizetaker, and also as a judge. Let me say that in the Class of 18's I requested my able coadjutor to decide without me, which he did; but, feeling that this might not be generally known, I thought it advisable, on my return home, to write to the Secretary of the flower show, saying that I was contented with the position assigned me, and declining to receive the amount awarded, desiring to "avoid even the appearance of evil."

I should think that amateurs must have hailed with pleasure the rule of the Royal Horticultural Society, which excluded the exhibitor in the larger classes from exhibiting in the smaller ones, as, where Mr. Hedge is, there is but little hope of any other competitor taking a first prize. The rule seems to me a good one, as it enables small growers to have some hope of a prize, which is almost out of the question when one has to enter the lists with those whose collection is as large as that of many nurserymen, and grown with perhaps greater care.—D., *Deal*.

THE ROYAL BOTANIC SOCIETY'S SHOW.

JULY 2ND.

THIS was the last Show of a brilliant and successful season; and it was not only equal, but in many respects superior to its predecessors. Although the dazzling colours of the Azaleas which lighted up the earlier shows were absent, and although the Pelargoniums, as a whole, were not equal in size or beauty to those previously exhibited, yet, as a compensation, the Stove and Greenhouse Plants were in greater abundance, the Heaths in greater perfection, the cut flowers more numerous and beautiful than ever. Then there was the Fruit—and such fruit! What Black Prince Grapes have ever been seen to equal those from Mr. Hill? At other shows he had exhibited three bunches weighing 8½ lbs. and 10 lbs. 6 ozs., and these were wonderful; but, more wonderful still, he now came with bunches weighing 13 lbs. 10 ozs., and 11 lbs. 10 ozs. for the three, and of which the largest could not be less than 17 inches long, and the smallest 14 or 15, and these perfectly ripe, and symmetrical. That such a display as that of Saturday last, unlike others which have been recently made, should be conducive to the advancement of horticulture cannot be doubted; and that such purely horticultural exhibitions can be made to pay their expenses, and leave a wide margin, not of profit, but of funds to carry out other objects connected with gardening science, the large and fashionable attendance of visitors on that occasion, amounting to many thousands, is abundant proof.

STOVE AND GREENHOUSE PLANTS.—The collections exhibited by Messrs. Whitbread, Gilbert, Fraser, and some others were remarkably fine, and, containing several kinds not before exhibited this season, they excited greater interest. That fine Melastoma Pleroma elegans, as shown by Mr. Whitbread, was covered with numbers of its highly ornamental purple flowers, and it was seen in fine condition in other collections. Ixora salicifolia with magnificent heads of reddish orange bloom came from Mr. May and Mr. Rhodes; and the old but very pretty white-flowered species alba, from the former and Mr. Peed, was also very effective. Allamanda, consisting of Schotti and cathartica, were very fine, particularly the former; Dracophyllum gracile was in good condition in several collections, also Rondeletia speciosa

Polygalas, Pimeleas, Vincas, Dipladenias, Statices, Rhynchospermum jasminodes, growing very gracefully, and covered with its white Jasmine-like flowers; and Roella ciliata, very conspicuous from its lavender and violet flowers. Leschenaultia formosa, with numerous scarlet blooms, from Messrs. Lee, forming a bushy little plant, was very pretty. Erica Parmentieri rosea, from Mr. Wheeler and Mr. Rhodes, was covered with its splendid deep rose-coloured blooms; Mr. Whitbread sent an immense Azalea magniflora in excellent condition, both as regards flowers and foliage; and from Mr. Gilbert came Kalosanthes superba, with truly superb scarlet flowers. Clerodendron Thomsoniae, from Mr. A. Ingram, though not fully out, was also very striking, and when better known this beautiful species will no doubt become a favourite exhibition plant. The prizes awarded were:—For sixteen, Mr. Whitbread first, Mr. Gilbert (gardener to E. L. McMurdo, Esq., Hastings) second, Mr. May, Hawkesbury Park, third; for ten, Mr. Fraser, Lea Bridge, first, Messrs. Lee second, Mr. Williams third, Mr. Rhodes fourth; for ten (Amateurs), Mr. Peed first, Mr. Chilman second; for six, Mr. Wheeler first, Mr. Kaile second, Mr. Page third, Mr. Cross fourth.

Fine-foliated plants were of the usual character, comprising Alocasias, Crotons, of which the narrow-leaved sort from Messrs. A. Henderson had the yellow variegation fully developed, and the plant formed a beautiful weeping bush; a very tall Dracaena indivisa from Mr. Williams; Latania borbonica, Encephalartos latifrons, the rush-like pendant-leaved Littæa juncea, and Sabal Blackburniana, a noble plant, from Mr. Taylor. Messrs. Lee were first in the Nurserymen's Class; Messrs. A. Henderson and Williams equal second. In the Amateurs' Class the collections of Messrs. Baines, of Bowden, Cheshire, and of Mr. Fairbairn, of Syon, who were first and second, were very fine; Mr. Taylor and Mr. Young were third and fourth.

FEENS.—Collections of the exotic species comprising large specimens of Cibotium princeps, Cyatheas, Gleichenias, Dicksonias, Todea africana, &c., were sent by Mr. Williams and Mr. Bull, who received first and second prizes; and those from Mr. Young and Mr. Martin, which were placed equal third, were also good. In British Ferns, Messrs. Ivery's fine collection, as usual, carried off the first prize.

ORCHIDS still made a fine display. Among those from Mr. Baker were the curious greenish-yellow-flowered Dendrochilum filiforme, Aerides odoratum majus, an old but very free-flowering species, of which this was an excellent specimen, Cattleya amethystoglossa, Saccolabium guttatum, Holfordianum with six fine spikes, Vandæ, Lælias, Cypripediums, &c. In the other collections we noticed the green-and-white-flowered Brassia verrucosa, the rare Brassavola Digbyana, Cypripedium Hookeri, and several good varieties of barbatum, Oncidium Lanceanum, Cattleya citrina, with bright yellow flowers, and which does well under cool treatment; Oncidium flexuosum, blooming, as it generally does, very freely; also a very fine example of Cattleya Mossiae from Mr. Penny, besides Aerides, Saccolabiums, Vandæ, Cattleyas, Lælias, Phalænopsis, in fine condition. A dark crimson and yellow Stanhopea, from Mr. Rhodes, attracted much attention from its remarkably large and handsome flowers; and by those who did not know that it was a peculiarity of the genus Acineta Humboldtii, producing a long spike of flowers from the bottom of the pot, was considered wonderful. This came from Mr. Parker, of Tooting. The prizes awarded were:—For twenty, Mr. Baker, first, Mr. Milford second, Mr. Peed third; for twelve, Mr. Penny first, Mr. Page second, Mr. Chilman third; for six (Nurserymen), Mr. Williams first, Mr. Parker second, Mr. Woolley third, Mr. Rhodes fourth; for six (Amateurs), Mr. Wiggins first, Mr. A. Ingram second, Mr. Wilson third, Mr. Wheeler fourth.

(To be continued.)

CLANTHUS DAMPIERI SEEDLINGS.

SOME time ago I sought your directions as to the culture of some Cianthus Dampieri seedlings, and was requested to let you know whether I succeeded in flowering them; with much pleasure I therefore do so.

I potted my two seedlings in a compost of peat, charcoal, turf soil, and sand, following your instructions as nearly as I could, and giving the plants a good place in the greenhouse.

Both seedlings progressed healthily for some time, but the most vigorous one about two months back suddenly drooped and gradually withered without any apparent cause, the stem of the plant, below the collar, and the roots seemed black and diseased, leading me to suspect that the drainage was faulty, although I had taken great care about it.

I am glad to say, however, that the surviving plant has thriven well, and during the past month has thrown out several splendid blooms in trusses of three or four flowers, with every appearance of continuing to do so for some time to come. The brilliancy of the flowers amply repays the attention required, and I have to thank you for the directions afforded, which have enabled me to flower the plant successfully.—A YOUNG AMATEUR.

P.S.—Is bast matting better for budding purposes than worsted or woollen thread? I budded many stocks with the latter last season with hardly a failure. What is the advantage of bast-matting strips?

[We know of no superiority that the one has over the other.]

FLAVOUR OF FRUIT UNDER GLASS v. THAT ON WALLS.

I AM indebted to "WYESIDE" for his temperate communication at page 437, in reply to my call for information as to fruit grown under glass being superior in flavour to that grown on walls. He says I have undertaken a very difficult task when I attempt to prove that those who have succeeded in growing as fine fruit under glass as others upon walls, ought not to have done so for physiological reasons. I never undertook to do anything of the kind. What I said and still maintain was, that fruit grown under glass is superior in flavour to that grown on walls in the full sun, was an assertion diametrically opposed to the laws of Nature as expounded to us by vegetable physiologists. "WYESIDE" says facts are against my argument; and yet he does not furnish us with a single fact wherewith to afford ground for a discussion of the topic, but leaves others to speak of them.

Whether does a Peach tree on a south wall or in an orchard-house enjoy the more light? This is the point on which "WYESIDE" asserts I am so much in error as to astonish him, yet he adduces no facts; and as for his *a priori* reasons, showing that orchard-house trees enjoy more light than trees on walls, I will show that they even bear out my argument. "WYESIDE" says, "A wall shuts out half the light of heaven." Admitting this (which I cannot as applied to Peaches on a south wall), it must follow that an orchard-house with an opaque back wall, ends, and sides for some height above the surface is as dark as the wall, from the opaque character of the back wall, darker from the total obstruction of light by the also opaque ends and sides, still darker again from the obstruction of light by the woodwork of the roof, and darker even yet by the impurities ever present even in the best glass, without adding another item to the darkness by the rays reflected, let the angle formed be what it may. If this be true of lean-to houses, how happens it that fruit grown in them is earlier than that in span-roofed houses? What is the cause of their being warmer? "WYESIDE" does not take cognizance of the fact in the one case, nor of the cause in the other. Is not fruit produced sooner in lean-to houses by that which "WYESIDE" says makes walls darker than orchard-houses? If a lean-to house be much lighter than a span-roofed, which I contend it is not, how comes a tree on a wall to receive less light than one surrounded by light on every side—such as one under a span-roof with glass ends and sides to the house? A tree surrounded by light on every side, as in a span-roofed house, does not receive nearly so much direct light nor even heat as one in a lean-to; for it is absurd to argue, that because a house presents a larger surface of glass (more than half of it to a diffused light), to the open firmament, that it must necessarily be lighter than another presenting its surface at such an angle that very few rays of light are reflected. I suppose "WYESIDE" is aware that it is owing to the greater proportion of rays reflected by the roof of a span-roofed house over that reflected by a lean-to, which causes the trees in the former to assimilate the food of the tree in the leaves more slowly than in the latter, through the less intensity of the light; and the heat being less also, less food

is pumped up into the leaves and the process of assimilation goes on more slowly, and the result is, fruit not ripe and the growth not perfected so early as with trees under a lean-to house roof. "WYESIDE" may explain this away by contending that a span presenting a larger proportion of exposed surface to the air is sufficient to account for the difference of temperature in favour of a lean-to, which owes its heat to the smaller proportion of glass surface presented to the cooling influences of the atmosphere. I admit it; but how comes the lean-to to be heated much more quickly than the span? For the same reason? Decidedly not. Very well, then, we come to the point at once. A span-roofed house affording light to its inmates on every side, they are indebted to refraction for all the light on the west side of the house when the sun's rays fall on the east; and are not Pears on a west wall the same? Cherries on an east wall or aspect are also indebted to the same refraction when the sun's rays are obscured from them by the bricks that intervene between them and the west side on which the sun's rays are falling; but is the light not less intense on the side of the wall opposite that on which the sun shines? I suppose a wall on the sun-side casts no greater shadow than the sun-side of a glass roof, and the trees upon it receive the sun's rays equally from top to bottom. But who can say the same of a glass roof? Why, the trees beneath it are indebted for the light they receive to that which passes through the glass, directly or indirectly, it is all the same; they cannot receive any or but little of that light which the angle of incidence causes to be reflected back into space. If it be as light on the north side of a wall, or in the shadow of anything that obstructs or causes a deviation from the natural course of the rays as in an open space where the sun's rays are not broken by some substance suspended or otherwise causing a deviation from the natural course of the rays, then are trees under glass in the enjoyment of more light than trees on a south wall. There is an equal amount of light on the earth when the sun's rays are obstructed by the clouds, according to "WYESIDE's" argument as when there are no clouds to intercept them.

"WYESIDE" again, speaking of light, says that an Apricot on a west wall is deprived of the light which is sufficient to ripen Cherries on the east side by the bricks that intervene. Suppose we take away the wall and the Cherry trees, would the Apricot trees have more light? Not a particle; for immediately we take away the wall leaves appear on that side and shut out the light from the others on the opposite side, rendering them as dark as they were when the wall prevented their receiving any light from that point; and, in addition, they are deprived of the heat absorbed by the bricks and the shelter walls afford.

Then as to trees on walls shooting at an angle from the wall on whatever aspect, does it not arise from the same cause as that which makes orchard-house trees grow upwards towards the glass? Surely trees shoot from walls for the same reason as that which causes orchard-house trees to grow upwards, the lowest branches to be weak and continually dying off—viz., towards the point from which the light is most intense. All trees on walls push their branches towards that which is necessary to their existence—viz., light. In whatever position or situation a plant is placed it is always found pushing its leaves towards the light.

"Does Mr. Abbey imagine that light proceeds only in direct rays from the sun?" asks "WYESIDE." I can only answer that the theory of light rests on three laws: 1st, The rays of light are straight lines, given and reflected in the same. 2nd, The angles of incidence and refraction are in the same plane, and equal. 3rd, The angles of incidence and refraction are in the same plane, and their sines bear an invariable ratio to one another for the same medium.

As to the Apricot from a wall with a pallid hue on the side next the wall. Is not that pallid hue due to the absence of the same agents that cause those in an orchard-house to be of a "sickly colour" all over—the absence of sun, its light and its heat?

But I must not lose sight of "WYESIDE" striving to make it appear that I consider it colder under glass than in the open air. If he refers to page 213, he will find that I state that I found the atmosphere 5° warmer in a span-roofed orchard-house than in the open air; but if he expects me to become converted to his views—viz., that heat is not inter-

cepted by glass, or that orchard-houses owe their warmth over that of the open air to any increase of heat caused by the passage of solar heat with its light through glass, I must say he expects me to assert that which I know to be erroneous. The best glass is that which stops the most heat, as Hartley's rough plate, for all horticultural purposes, when the structures are heated or not heated, such structures being warmer than the interior of houses covered with 16-oz. glass. Let "WYESIDE" keep a register but for a week of the temperatures of three structures equal in their cubic measurements, and also equal in the area which is to admit the sun's rays, and make the latter surface of—1, 16-oz. glass; 2, Hartley's rough plate glass; 3, oiled paper; and he will find more heat or a higher mean temperature under 3 than under 2, and higher under 2 and 3 than beneath 1. Further than this, let him take a large pane of glass, and place it over a thermometer so that the sun's rays will pass vertically through it, and he will find the sun's rays do not raise the mercury more than were there no glass over it; but suppose he place the pane of glass so that the angle of incidence be more than 45°, the mercury sinks proportionately lower than when under the pane of glass with the sun vertically over it.

Again: let him erect a house with an angle of 25°, a second 35°, a third 45°, against a south wall, or with an opaque back wall, and complete his experiment by erecting a span-roofed house with the ends respectively north and south, with the roof at any angle he pleases, and glass down to the ground if he chooses; in short, have glass where we have some opaque material in the first three. All shall be equally well stocked with Peach trees, and all equally well attended to, and which will furnish ripe Peaches the earliest? Why, they will come in order as named, the span-roofed house being fully a month behind the first of the others, and this with double the amount of "glass not intercepting the heat," according to "WYESIDE," for it is so hot in houses with a glass roof securing light for the trees enclosed on all sides, as to render the heat quite unendurable. Mr. Rivers tells us such a climate is quite delightful. I myself had any time rather spend a week in a span-roofed orchard-house pinching-back the young growths, or otherwise attending to its inmates, than remain an hour in front of a south wall trimming Peach trees trained to it during very hot weather. The air is really so bracing in the former, and so roasting in the other, as to leave no doubt about which is the most comfortable situation to be in. The heat is another question, for heat as determined by the senses is no criterion to go by. In fact, degrees of heat and moisture cannot be determined by the senses with any degree of accuracy.

In conclusion, I can only say that out of the six northern counties of England, and the whole of Scotland, we have but two cases of Peaches and Nectarines being grown in cold or unheated orchard-houses in that extensive range of country, much the largest half of Britain, one cited at Seggieden, near Perth, by "S. R.," and the other by "PENDLE," near the famous peak of that name in Lancashire. Mr. Pearson also states the success of orchard-houses at Prescot, but whether Peaches and Nectarines are successfully grown in houses unheated and detached from a wall is not stated. This is all the evidence we have been favoured with relating to the success of orchard-houses in the north. Surely there have been more successes than those named. I have grown Grapes in unheated lean-to houses within the sound of the striking of big "Peter" of York, and had them ripe by the races held there in the last week of August; Peaches and Nectarines also in unheated lean-to houses in the latter part of July, and beginning of August; and gathered Earyl Anne Peaches from a south wall in the second week in August; and gone night and morning with a peck basket and collected fallen Peaches from a net in the last week in August and on through September, and more than once have had to go twice, the basket being too small to take all at once. At Bradford, however, such things are not seen, though I have seen Peaches ripen on a wall, yet I looked into all the hoorchar-d-uses round there, from that under 20 feet in length up to those 300 feet long and 20 feet wide, and never yet saw a crop in any of them, nor in those situated in much more favourable localities.

Mr. Rivers, after giving us a racy account of his liking for Cherries, and some excellent information as to their cultiva-

tion under glass (and I can bear witness to how well they do under glass, in unheated orchard-houses in the north), expresses his regret at the "rather low idea of the capabilities of the gardeners in the neighbourhood of Bradford," which, he says, has been given by me, and this in consequence of my having given an account of the failure of Peaches and Nectarines in orchard-houses in that locality. He says that the gardeners there "ought to be able to conquer all the difficulties of the position." They, let me tell him, are qualified to do so; but it will be by heating their orchard-houses, if they mean to have Peaches and Nectarines with certainty, and not in unheated structures. They have grown as good fruit as ever was eaten, but they have received little aid from orchard-houses, except in the matter of Cherries, Plums, Pears, and Apples. Unheated orchard-houses answer well for these, as I stated on former occasions.

Mr. Thomson may deserve great credit for growing Grapes, and having them ripe in January, but I believe he was not the first to accomplish the feat of having ripe new Grapes on the 1st of January; for, some twelve years ago, Mr. Watson, gardener at Ribstone Hall, Knaresborough, Yorkshire, at that time had some nice ripe Grapes, when I called there early in January, growing in a Pine-stove, specimens of which were exhibited at one of the Horticultural Society's meetings in January, and duly reported in the "Transactions" of that Society. At Harewood House, the residence of the Earl of Harewood, I believe Grapes were produced by Mr. Fowler on New-year's Day before Mr. Thomson accomplished the feat at Dalkeith. As for the ripening of Grapes in January teaching us to "look doubtfully on our present laws of vegetable physiology," as far as regards the influence of light ripening fruit, I must refer Mr. Rivers to the exhibiting of old Grapes *versus* new in January, 1863, the former being contributed by Mr. Tillery, Welbeck, and the latter by Mr. Thomson, Dalkeith, with a view of deciding on the relative merits of old over new Grapes. The old, ripening with more "light and sun heat," were unanimously pronounced the best in point of flavour; whilst the new were the freshest, and consequently most attractive in appearance, and as such were preferable to old Grapes. It was said that Mr. Thomson's Grapes were not so "well coloured nor so well flavoured" as they were from the same Vines in the January preceding, which was attributed to the prevalence of cloudy weather whilst the Grapes were ripening. New Grapes, then, ripened in January, were not equal in flavour to those ripened at a period when the sun's light and heat were more powerful.

In reference to my visiting either of the places named by Mr. Rivers, I do not see the necessity for going to either Nottingham or Liverpool to see what I every day see on my present employer's garden walls and espaliers. If Mr. Rivers be at all desirous of testing the capabilities of Yorkshire gardeners, he has nothing to do but send some of his very best orchard-house fruit to any of the York, Leeds, or Bradford Shows, and they will teach him to have anything but a "low idea" of them in future.—GEORGE ABBEY.

[We consider this a very unprofitable discussion. We have eaten Peaches and Nectarines ripened under glass nearly as fine, nearly as luscious, and nearly as high-flavoured as the best ever grown against a wall. Grant that they always are more or less inferior—what then? They are grown under glass for earliness and certainty. As to less light being received by fruit under glass than when grown in the open air—granted; but what then? Fruit trees are grown under glass for the purpose of retaining heat to them. As to Peaches not being ripened in an orchard-house at Bradford, we are quite sure that Mr. Abbey only states what he knows; but the fact only proves that there must be something peculiarly unfavourable in the situation of that town, for it is certain that Peaches are so ripened in many places much further northward.]

SKELETONISING LEAVES AND SEED VESSELS.

PUT the specimens in rain water, in which they must remain till decomposition takes place, so that they may be freed from the pulpy matter, and after macerating in clear spring water dry them between sheets of blotting paper,

then bleach them in diluted chloride of lime sufficiently strong to burn the tongue. When whitened, to be washed again in clean water, and dried by sun or fire. Take care not to allow the destructive process to be carried on too long, or it will injure the fibres, nor must they remain too long in the chloride. They may be cleansed, if leaves with strong fibres, with a softish nail brush, or pricked out with a pin, when the pulpy matter adheres too strongly to be removed with water. Some leaves take months to decompose. No two years are alike as to the time of gathering, or time required for the process. If obliged to be taken out of water during the process, for travelling, &c., the leaves must not be allowed to dry, but be kept folded in a damp towel. The softer the water the better. You must not bleach the leaves directly, but wait till you have a quantity to whiten.

LEAVES.—Ivy, Magnolia, Pear, Apple, Butcher's Broom, Andromeda, Tulips, India-rubber, Sycamore, Holly, Aspen, Poplar, Apricot, Lemon, Orange, Box, Lime, Hornbeam, Passion-Flower.

SEED-VESSELS.—Stramonium, Henbane, Poppy, White Cherry, Campanula, Lavatera, Mallow, Hydrangea, Horehound, Sea Holly, Deadly Nightshade, Radish, Flax, Hemp, Stinging Nettle, stalk of Cabbage, tuber of Turnips.

MESSRS. IVERY & SON'S NURSERY, DORKING.

Of the many beautiful spots along the ridge of the North Downs, which stretch nearly across the county of Surrey, there are none from which a finer or more diversified view can be obtained than from Box Hill, in the neighbourhood of Dorking. This, as the name implies, is remarkable for the quantity of common Box (*Buxus sempervirens*), growing there, and believed to be indigenous; and which certainly adds materially to the beauty of the place. At the foot of the hill is a station on the Reading branch of the South-Eastern Railway, known as the Box Hill station, thus affording a facility for such as live at a distance to visit this delightful spot. The convenience of approach is largely availed of by hundreds of persons, and among them, doubtless, by many of your readers who love to enjoy the beauties of nature; so that every fine day in summer numerous groups of cheerful faces may be seen scattered over the green turf, enjoying their picnic and the glorious landscape spread before them.

To enter into detail as to the many salient points of interest that can be viewed from Box Hill is not, however, the object of this article; but to remind the reader, and all interested in horticultural pursuits, that less than ten minutes walk from Box Hill station is one of the most important nurseries in Surrey, and, in some respects, in England—viz., the establishment of Messrs. Ivery & Son: for here originated many of the most splendid of the varieties of Azalea *indica*, that have excited such general admiration at the metropolitan and other flower shows, and which are found in every private collection of merit in Europe; and here also exists the wonderful collection of British Ferns that has now become an adjunct to the great floral displays. When an improved arrangement of those shows shall be effected, nothing will be found more suitable to aid in moderating the overwhelming blaze of the gorgeous specimens produced by the skill of our gardeners than the lovely foliage of the British Ferns.

A visit to this establishment, then, will be found highly interesting, and although mine was made when the Azaleas were out of bloom, there was much to be pleased with. A brief inspection of the various houses in which the stock of Azaleas are kept was sufficient to be convinced of the excellent state of health and fine condition of the plants ready to be sent out, of which there are several thousands. Among the most important may be mentioned Iveryana, Criterion, Admiration, Barclayana, Gem, Beauty of Reigate, General Williams, Rosea elegans, Striata floribunda, and several other approved kinds, all of which were originated by Messrs. Ivery; and more recently—Carnation, Tricolor, and Leviathan. Of novelties about to be sent out, Beauty of Dorking is ready at the present time. It is white striped with rose, of fine form and good substance. Forget-me-not, reddish purple, will be ready in May, 1865; and Fascination, rose edged with white, in the autumn of next year. Those last-

named will prove great acquisitions. Vast numbers of plants of all the leading kinds raised by other growers are in equally fine condition.

Next, and in no way inferior in merit, is the magnificent collection of hardy Ferns, chiefly British, with about a dozen exotics. Altogether there are in cultivation here 158 varieties of British Ferns, but very many of these originated here as the offspring of other kinds. At present there appears to be no limit to the number of varieties likely to be obtained. Variations occur every year, and some of them of great beauty and distinctness; but it also happens that the seedlings (if I may use this term as applied to Ferns) frequently go back to the form of their original parents. It is worthy of note that all the Ferns actually found wild in this country are kept in stock, so that every lover of this description of plants can readily obtain kinds that would take a long time and distance to find in their wild state. The British Ferns, then, when brought under the training of the skilful cultivator, are yearly showing some new feature of interest and, because of their hardiness, will at no distant period be eagerly sought for as important items in garden decoration, for dinner tables, plant-cases, and many other purposes where foliage is required as much as colour. Their cultivation is also easy, therefore they may share the attention of all.

The collection of Messrs. Ivery is familiar to the visitors of the great metropolitan shows; but to such as may not have had the opportunity of seeing them the subjoined list may be depended on as containing some of the most beautiful and distinct kinds. *Adiantum capillus-Veneris* (Common Maiden-hair). *Asplenium*.—*Asplenium fontanum* (Smooth Rock Spleenwort); *septentrionale* (Forked Spleenwort); *viridis* (Green Spleenwort). *Athyrium Filix-femina* (Lady-Ferns).—*Athyrium Filix-femina apusiforme*, very beautiful, the outline of the frond resembling a fish, and the pinnae little fishes; *corymbiferum*, fronds and pinnae bearing light tassels at the ends, a vigorous grower, very distinct and lovely; *crispum*, a dwarf tufted variety, very curious; *diffissum*, rather rare; *Fieldiae*, a new and striking variety, it should be in every collection. The same may be said of *Frizelliae*. *Laciniato-lineatum* and *plumosum* rank among the most beautiful of the Lady-Ferns. *Blechnum spicant* (Common Hard-Fern).—The best of the tribe is probably *Blechnum spicant ramosum*, all the fronds being beautifully crested at the ends. Nearly as good and distinct are *polydactylon*; *strictum*; *subserratum*; and *subserrato-imbricatum*. *Lastrea* (*Aspidium*).—*Lastrea Filix-mas* (Male Fern): *Bollandiae*, one of the handsomest of the non-cristate varieties of *Filix-mas*, and very distinct; *crispa* is quite a unique kind, differing from the species in the widest manner imaginable; *cristata* is a fine variety; *cristata angustata*, a new and rare form of the preceding; and *Jervisii* is an interesting variety; *Osmunda regalis* *cristata* is very handsome. *Polypodiums*.—The four following are pretty:—*Polypodium Dryopteris*, *Phegopteris*, *Robertianum*, and *vulgare cambricum* (Welsh Polypody). *Polystichums* (Prickly Shield-Ferns).—*Polystichum angulare imbricatum*; *angulare proliferum*; *angulare Wollastonii*; and *lonchitis* (Holly Fern), are the most desirable. *Scolopendriums* (Hart's Tongue).—Of about thirty of the *Scolopendriums*, the following half a dozen are good:—*Scolopendrium vulgare sculpturatum*; *vulgare Wardii*; *vulgare crispum*; *vulgare digitatum*; *vulgare macrosorum*; and *vulgare muricatum*.

The following four new Ferns are now ready for distribution:—*Athyrium Filix-femina mucronatum* and *glo-meratum* (which have both received first-class certificates from the Royal Botanic and Royal Horticultural Societies); *Athyrium Filix-femina Parsonsiae*, and *Polystichum aculeatum acrocladon*. The last received a second-class certificate from both Societies, but when shown it was not fully developed, so that its merits have not yet been fully recognised.

Of the nursery stock out of doors, the most prominent are the Conifers, on account of the number, size, and form of the specimens. The Home Nursery, small in extent, contains a large number of fine plants of all the most important kinds used for ornamental purposes. Wellingtonias are from 8 to 12 feet high; and among them is one very interesting at the present time from the circumstance of having twelve perfectly-formed cones. The cones were first noticed

last summer, but, not coming to perfection in the autumn, were suffered to remain, and are now firmly set; but it is not certain that they will produce seed. My own supposition is, that they are abnormal, caused by frequent removals of the plants. They are formed round the main stem at the end of the growth of 1862. Also deserving of notice is a *Cupressus Lawsoniana*, with abundance of seed.

The Araucarias are very fine. From thirty to forty of them, ranging from 10 to 15 feet high, planted in close proximity, offer a curious and interesting sight, such as can only be seen in the old-established nurseries of England.

It is a mistaken notion that Conifers are only fit for parks and large pleasure grounds. They should be planted everywhere, in the smallest as well as the largest gardens (so many of fastigiate habit have, of late years, been introduced that the size can no longer be pleaded as an excuse), much more the compact kinds, as *Thuja* (*Biota*) *aurea*, *Juniperus ericoides*, &c. Any one taking the slightest interest in his garden, and looking at the planted space in front of Mr. Ivery's house, filled with Conifers of all sizes and forms, would not hesitate to acknowledge their beauty, and the wide range of their adaptability.

Among the other plants most worthy of note is a large one of *Lonicera aureo-reticulata*, which stood out in a rather exposed situation the whole winter. It continued growing the whole time, excepting in the severe frosts, when very small portions of the ends of the shoots suffered trifling injury. The hardy character of this beautiful climber is thus sufficiently proved.

At the upper end of the nursery on the north side of the boundary-wall is a collection of Ivies and Vincas, suitable for shady and other places, where many things will not grow. Of the former Mr. Ivery tells me he has thirty-nine varieties. Many of them are very distinctly striped and blotched.

The Roses are here, as they must be in every nursery, an important branch of the business. A judicious selection of the really best kinds is infinitely better than an indiscriminate propagation of the good and bad that have always been muddled together in extensive collections. Without getting behind the times, the Messrs. Ivery are careful to keep out, as far as possible, the rubbish sent to England every year by the French growers. At the time of my visit there were good blooms of *Triomphe d'Angers*, *Triomphe de Caen* (good colour, but rather too thin), *Deuil de Prince Albert*, *L'Elegante*, *John Hopper*, *Charles Lefebvre* (good), *Senateur Vaisse* (still A1), *Cecile de Chabrillant* (ditto), *Duchess of Norfolk*, *Mademoiselle Bonnaire* (one of the best light Roses), *William Griffiths*, *America*, *Général Jacqueminot*, *Baronne Prevost*, &c.

In conclusion, I have to acknowledge the courtesy and kind attention of Mr. Ivery in pointing out the various objects of interest.—ADOLPHUS H. KENT, Blechingley.

DESTROYING THE RED SPIDER.

The mixture used for the destruction of the red spider (and noticed by you at page 461) is not made from gum, but sago flour—a much cheaper mixture than gum, as it costs in Liverpool only about 10s. per cwt. (Potato starch will do equally well, if sago flour is not obtainable). My starch was made in the following manner:—2 lbs. of sago flour were made into a thin paste, thickening it in the same way as the laundry-maids do when making starch. This paste was then poured into three gallons of boiling water, and the mixture well stirred up until it came to boiling again, it was then mixed with six gallons of cold water, and applied to the trees immediately by a syringe having a jointed nozzle. Thirty trees in my orchard-house were syringed with the effect shown on the leaf sent to the office of THE JOURNAL OF HORTICULTURE.

It cannot be used too soon after being made. The cold water with which it is mixed reduces the temperature to something like 100° F., which is quite safe, but if allowed to get cold it has not the same fluidity as at first.

I think it best suited for Peaches and Nectarines. The pubescence on the under side of the leaf in the Apple and the Plum, hold the film of paste more tenaciously than does the leaf of the Peach. For the thrips it ought to be very fluid to get close alongside the midrib of the leaf, and at the

same time be so strong as to impound them. This requires greater strength than is needed for the red spider.

I think the trees require syringing two or three times, as

a single leaf missed is sufficient to stock the tree with those pests again.—T. G.

P.S.—It is not effectual for the aphis.

175018

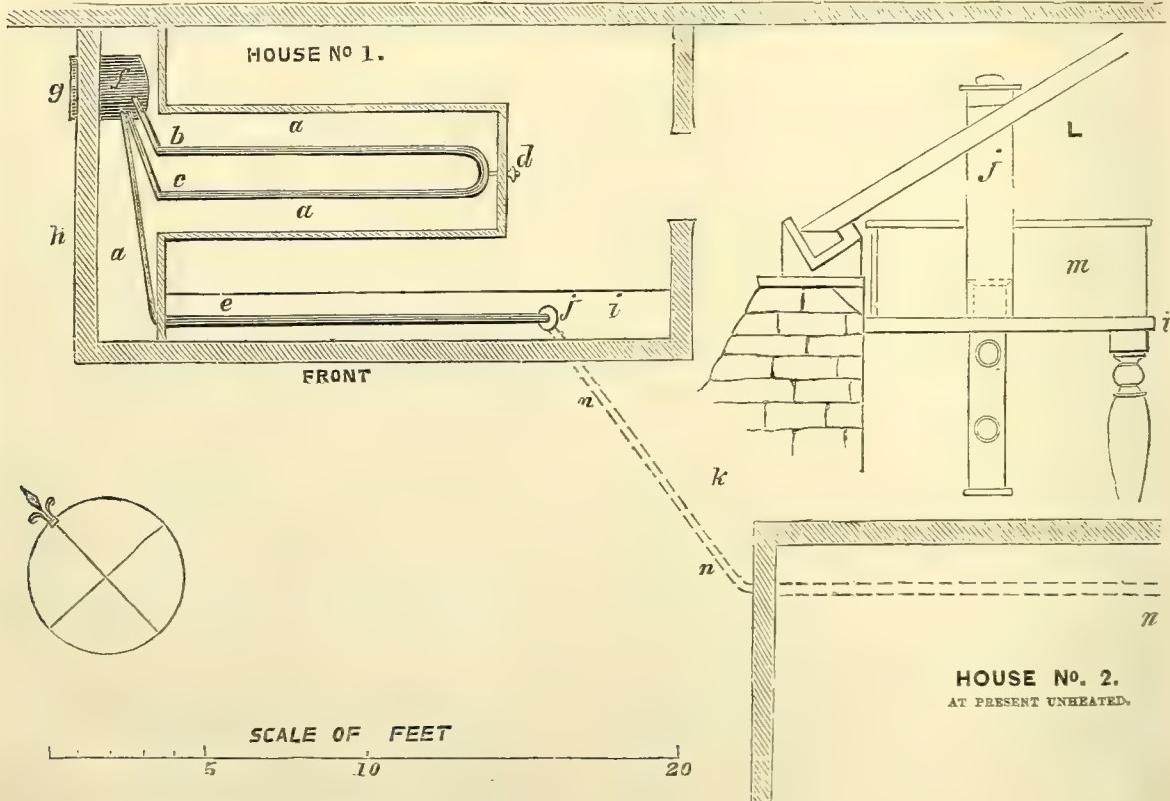

MORE FIRE THAN NEEDFUL TO HEAT THE WATER CIRCULATED.

LAST autumn I put up a small house (No. 1) chiefly for propagating purposes, a semi-span, on Hereman's Paxtonian principle, 20 feet by 10 feet. It was heated as shown in the plan. I soon found that I had not enough water for my heat, for no sooner does the fire burn up than it boils. At first I had a half-inch gas-pipe led through the glass roof at *j*, for the escape of the steam; but this was quite insufficient. Then I had a tube of zinc made 6 inches in diameter, secured over the pipe junction, and carried through the roof, and then covered with a perforated lid—the whole shown at *j*, in the section L. But this scarcely mends the matter, for the space enclosed in this six-inch pipe is insufficient to hold the swollen water at boiling point; and so, ever and anon,

it rushes and roars up, throws off the lid, and pours in streams upon the glass roof, penetrating down to the plants beneath, scalding them, and filling the house with steam. This is difficulty the first.

Now, as a remedy, it has been suggested that I have a parallel-sided cistern made of zinc or sheet iron, to hold about twenty-four gallons, and put this instead of the present steam-pipe, soldering it over the open junction, as shown by the section (m), dotted in section L. This would have a moveable lid, for supply, and it is thought that the increased contents would both leave ample room for swelling under heat, and also by the increased body of water obviate the tendency to too ready boiling.

BACK WALL.

- a*, Walled pit, filled with tan, for plunging.
- b, c*, Flow and return four-inch pipe for bottom heat.
- d*, Tap at end of ditto.
- e*, Flow and return four-inch pipe for atmospheric heat.
- f*, Boiler.
- g*, Fireplace.
- h*, Stokehole, under a shed.

- i*, Front shelf.
- j*, Steam-escape pipe.
- k*, Garden walk.
- L*, Section of front shelf at *j*, on larger scale.
- m*, Proposed waste-cistern.
- n*, Proposed continuation of pipes to House 2.

Please to give me your opinion on this, and if you approve, say whether the proposed cistern should be of zinc or sheet iron.

Now then for difficulty the second. I want to put a little heat into house No. 2, and think that my boiler (*f*) is adequate to the work. The distance from house to house is about 9 feet, and it is proposed to carry one-inch connection-pipes from the flow and return at *j*, to similar flow and return four-inch pipes to be placed in house No. 2. The proposed connections and pipes are indicated by the lines (*n*). But the space between the houses is occupied by the garden walk (*k*), which cannot be removed. May the connection-pipes dip beneath the gravel, and rise again to

their proper level within the house, No. 2? since their level, even when so buried, would not descend nearly so low as the point at which each pipe respectively issues from or rejoins the boiler. Please to tell whether such a dip is practicable.

I have omitted to say that as the heating of house No. 2 will only be occasional, while the heating of No. 1 is constant, the pipes (*n*) must each have a valve or stop; but this will present no difficulty, I presume.—ORCHIDOPHILUS.

[The primary cause of your trouble is having too much fire for the body of water to be heated, which causes the water to boil, and very likely to form steam next the boiler, the force of which throws the water up the six-inch

waste-pipe which you take right up through the roof of the house. We have had similar trouble in small houses and pits, from the expansion of the water when heated to or near the boiling point. If you have no more heat than you want, with the pipes thus hot, you had better add more piping, and not have them so hot, as the heat given off from the pipes at from 200° to 212° is very trying for tender plants. It would be safer not to have the water above 170°, or lower than that. Then the water would expand less. If, with water at 170°, or lower, you will have enough of heat, then the next point will be to moderate the strength of your fire, either by using inferior fuel or banking-up with ashes, and keeping the ashpit-door close whenever you have obtained as much heat as you want. By this means a gentle uniform heat may be kept up under any boiler, as the draught, if not regulated by the ashpit-door, can also be regulated by a damper. If from neglect or other causes there would be a doubt of this answering, the great means of safety would be your proposed expansion-cistern. It matters not how this is fixed, whether by the side or on the top of the open end of the pipe, provided the cistern communicates with the pipe and stands mostly above it. When the fire is lighted the water in the cistern should not stand much above the orifice of the open pipe. This will afford all that more room for expansion of the water; and if the cistern is covered, to prevent the escape of vapour as the water cools, there will be plenty of water to fill the pipes and boiler, with, now and then, a little addition being made to it.

Now, but for your safety-pipe through the roof, there would be danger of an explosion. With that safety-pipe, and the large discharge you speak of, there is danger of air getting into the pipes, especially the lower ones for bottom heat; and then, not to speak of danger, it ought to be generally known that a body of air enclosed between two columns of water gets, for all circulation purposes, as impassable as a barrier of solid rock. We perceive you have a tap or turncock at the farther end of the pipes for bottom heat, and, we presume, at the highest point of the pipes. The turning of this will let off any accumulated air; but why not have an open gas-pipe going outside the house instead, which would be continuously self-acting, and save you all the trouble of turning the tap? If a little hot water was your object, you could obtain that from your cistern; but for all delicate purposes it is best to use pure soft water, warmed in the house by being set over the cistern.

As to the material for the cistern, either zinc or sheet iron will answer well enough, but they will soon oxidise. If either is dipped twice in a galvanising trough they will last much longer. We would as soon have a wood box, say of 1½-inch boards, well beaten and joined at the corners. This kept constantly supplied with water will last a long time. Even if lined with zinc or thin lead both will last much longer from the support of the wood. As already stated, the large cistern will be the best safety valve.

Secondly. As the junction-pipes to the second house, even when under the gravel path, will not be so low as the pipes in the first house when they issue from the boiler, the simplest mode of heating the second house, which only needs heat occasionally, would be to take a flow-pipe from the proposed cistern, which you could plug up when not wanted, with a wooden plug. But the return-pipe must not return to the cistern, but form one of the other returns, or communicate at once from house No. 2 to the bottom of the boiler. We state this because it is best that the return-pipe from No. 2 should not rise, but rather decline from thence to the boiler. You might have taken only one flow-pipe from the boiler to the cistern, and from thence taken pipes for bottom heat, or top heat, wherever you liked, provided the pipes in no place were lower than the boiler, and the return-pipes, if anything, fell to the bottom of the boiler. The one-inch connecting-pipe you propose must be bedded in sawdust, or some non-conducting material, or it will lose much heat in the course of 9 feet. We would prefer at least a two-inch pipe.]

PLANTS FOR SMOKY LOCALITIES.

The reply which you have given to "L. H. S." shows you to be well acquainted with all the trees and shrubs which can grow in the vicinity of smoky large towns.

I live a mile distant from the centre of Manchester, on the east side. My garden is protected either with trees or buildings, except from the north. Limes and Elms appear to grow well for two or three years, and then either break off midway down the trunks, or, as if by magic, die in a moment. Poplars are thin, ragged, and unsightly, and are certain to die off. The Copper-leaved Beech holds its place, certainly, but with great struggling. The Mountain Ash does tolerably. The Horse Chestnut grows freely, but never blooms. The north and north-west winds affect the young leaves severely, making a wreck where abundant foliage existed. Pear trees grow well, but bloom only occasionally. This year three Pear trees, each of them at least 45 feet in height, have been profusely covered with leaves; one only bloomed, the other two disdained the trouble. Thorns grow well, and flower freely, both white and red. Lilacs, Gueldres Rose, Siberian Crab, and the Elder do well, more especially the latter, which seems as if it took a pride in combating the enemy, smoke, and routing it altogether.

Azaleas grow well, the yellow one more freely than any other sort. The Azalea thrives best when it is protected from the keen blast or the blazing midday sun. But of all the evergreens which thrive here let me sing the praises of the Rhododendron. Some of the less hardy varieties have great difficulty in maintaining their footing, and indeed, like consumptive people, die off. Our garden would be nothing without the Rhododendrons, they are charming and beautiful whether in flower or not; waving their heads with every breeze of wind, they become the most polite and courteous of evergreens. Aucubas do very well indeed, they grow up into strong bushy trees, suffering from nothing but unkind Jack Frost. White and yellow Brooms, as you say, do fairly, but that is all that can be said of them. Young Hollies appear to be doing well, but their seniors keep on disappearing. Laurustinus will not do; whilst the *Ledum latifolium* make their balls of snow every season. The Ribes thrives very well. Weigela rosea will not bloom, coax it ever so much. Privet is successful, and makes wood freely. Laburnums are very satisfactory for a town buried in smoke, but when compared with those grown in more favoured situations they are scarcely worth naming.

I have thus gone through almost all the kinds I am able to grow, which agrees with nearly all you have written. There is, however, one remark I am desirous of making to all who desire to have trees and shrubs in the neighbourhood of large towns, and it is this—that if they want to be successful they must look carefully after them, and never cease their efforts in protecting them from the enemies which they have to fight against.—H. A.

NEW STRAWBERRIES.

THE ROYAL HAUTBOIS.—Through the kindness of the Rev. W. F. Radclyffe, of Rushton, we have received a basket of the fruit of Rivers' Royal Hautbois, which, notwithstanding the distance travelled, came in excellent condition. This is by far the best variety of the Hautbois we have ever seen. It is the largest in size and the most abundant bearer, and the flavour is superior to any other of the Hautbois. The colour, like that of all the other varieties, is partly purplish rose and partly pale yellowish; and the flavour, as a friend remarked, was "like Strawberries and cream."

MR. DE JONGHE, of Brussels, has sent us specimens of two new Strawberries which we think will prove useful additions to those already in cultivation, if it were for no other property than that of bearing a long journey without injury. In both of these the flesh is so firm and solid that the condition in which we received them was most excellent, and the flavour was not in the least destroyed.

Bijou.—This is evidently of the same race as that other excellent variety raised by Mr. De Jonghe called La Constante. The stalks of the leaves and fruit are short and stout, clothed with spreading hairs. The blade of the leaves is of a glaucous green beneath, and a clear shining dark green above. Flowers small.

Fruit not so large as that of La Constante, from which it was raised, ovate or conical, regularly formed, and having large seeds, which are level with or rather prominent on the

surface. The skin is of a clear, varnished cherry-red, well coloured all over the surface. Flesh firm and solid, white throughout, juicy, rich, and with a sprightly flavour.

This seems a very hardy variety, judging from the leaves and fruit that were received.

SOUVENIR.—This is apparently of more luxuriant growth than Bijou and La Constante, but it has all the appearance of belonging to the same hardy race. It is an immense bearer, and produces masses of noble fruit. The stalks of the leaves and fruit are clothed with spreading hairs; the leaves are broad, roundish, and deeply dentate, of a dark and somewhat shining green above.

The fruit is large, sometimes very large, varying from rounded ovate to long conical, and in some instances it is irregular and corrugated in shape. Seeds large and even with the surface. Skin of a uniform shining cherry-red colour. Flesh white, firm, and solid, juicy, richly flavoured, and with a fine pine-apple aroma.

This is a very excellent Strawberry, and, in our opinion, surpasses all the other varieties raised by Mr. de Jonghe.

DESTROYING THE GOOSEBERRY CATERPILLAR.

IN No. 168 I see your correspondent complains of the leaves of the Gooseberry tree being injured by the wash, the recipe of which I sent you. This I suspect was owing to the soap not being sufficiently dissolved. In that case, wherever the clots of soap touch the leaf, they leave a brown speck similar to the mark of the Celery grub, but if care is taken in this respect, I still adhere to my original statement, that it is the best cure for the caterpillar pest. Only yesterday I discovered some young trees affected. I instantly watered them over with the solution from a fine-rosed water-pot, and in less than half an hour the caterpillars were dead by hundreds on the ground.—EVAN YORK NEPEAN, Bucknall Rectory.

THE question of the Gooseberry caterpillar having so frequently come before our notice, and being still under discussion, I beg permission, among the rest, to offer a few remarks on the subject; and, at the same time, to give a brief description of its habits, and the various changes it undergoes during its season, which, I think, will tend to show how easily parties may be mistaken when guided only by fancy and hearsay.

About thirty or thirty-five years ago my trees were so infested with these destructive larvæ that I was induced to watch very carefully the different movements and changes, both of these and other insects destructive to vegetation. But to proceed with the caterpillar.

This pest is the progeny of a very small fly, a species of *Tenthredo*. The fly of the first brood emerges about the end of March or beginning of April from its chrysalis state, in which it has continued all winter, a few inches deep in the earth, under the bush. Each insect deposits its eggs, end to end, sometimes to the number of thirty or forty, along the ribs and under the expanding foliage. Here they remain in the embryo state a few days, till nature pushes them forward into living predators; and in a few days more marks of their existence will be visible upon the foliage—viz., small round holes, like pin-holes, to the amount of the number of caterpillars. After the insects produced upon the several leaves have devoured those leaves, they then spread over all the other unoccupied parts of the trees, consuming them leaf by leaf, until they are full-grown; and then nature bids them retire from the bush, preparatory to the appearance of a second brood, which will be about the end of May or the beginning of June, when the caterpillars may be seen casting their maculated skins amongst the remaining leaves of the trees and the weeds under them, when they enter the earth a few inches as before, and there remain about six weeks, and again leave the cocoon or case to establish the latter brood, which feed as usual until the caterpillars are full-grown, at which time they retire into the earth for their winter quarters.

After having fully satisfied myself about their habits, &c., my next step was to provide a remedy for these ravenous predators. I first tried salt and water, and in about half an

hour the trees were in a dying state. My next application was alum and water, 1 lb. to eight gallons of water. This had the effect of dispersing them, only to wander over the branches and upon the earth. Some, however, died, while others in a day or two resumed their work. I then tried common brown or mottled soap, thinly sliced, and dissolved in gently-boiling water; to this I added six gallons of rain water and two gallons of tobacco water. This mixture was applied with the engine in fine spray over the bushes, and followed by a man with a fine whisk, dashing the wet gently in amongst the foliage. This treatment proved effectual, and destructive to the caterpillars. But alas! like many other things now-a-days, both soap and tobacco water are no longer genuine: indeed the tobacco water of the present day is useless. For the next remedy: when the caterpillars became more advanced in growth, or nearly matured, a piece of canvass was provided, say 5 feet square, a slit was cut halfway through it, and it was drawn by two men round the tree, the stem of which was then struck smartly once or twice with a stick provided on purpose, with a cross-piece, 6 inches long, nailed on the end of it, covered with cloth to avoid bruising the trees. When the stem was struck down came all the pests upon the canvass, which was emptied from time to time, and the caterpillars destroyed. This was an important operation, for it removed all apprehension of another brood. But prevention is better than cure, and I am of opinion that picking off the leaves the moment they exhibit the small round holes mentioned above, is decidedly the best plan of all, and they must be looked for about the two periods I have named above.

It may appear a tedious process; but when we consider the great mischief that is prevented by destroying these young predators before they quit the leaf they are produced upon, and spread over the whole tree, I think the trouble will hardly be worthy a consideration. I may just add that neither placing Elder, Broom, Furze, nor, indeed, any other plants, in the bush will have the desired effect; and all applications about the roots are useless, as the shell protecting the chrysalis is so hard and well manufactured that no application can penetrate it. I can only help your clerical correspondent over his mistake in imagining the branch of Furze placed in the Gooseberry bush to have destroyed the caterpillar by supposing that it was most probably leaving the trees at this time, preparatory to its first change.

In conclusion, I may just observe that I have not a single Gooseberry caterpillar, I think, in my garden, and have not had for years, owing, I really believe, to the encouragement I give to birds. Blackbirds and Thrushes, with other birds, are singing delightfully all day long; and large armies of that much-despised bird, the Sparrow, spread themselves over the ground, daily gathering caterpillars, *aphis*, &c., not only from the Gooseberry bushes, but from most other kinds of fruit trees, shrubs, &c.—JOSHUA MAJOR, *Landscape Gardener, Knotthorpe, near Leeds.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE frequent showers we have had of late have been very favourable for all necessary operations. Every yard of ground that can be spared should be prepared and planted with winter vegetables. Stir the surface of the soil amongst all growing crops where practicable; it will enable the rain to penetrate through it with greater facility as well as check evaporation. The early crops of *Peas*, *Spinach*, *Radishes*, and *Cauliflowers* should be cleared off the ground as soon as they are exhausted. The ground, well manured and dug, might be planted with *Cauliflowers* or *Walcheren Broccoli*. Continue to ridge out *Celery*, and plant the *Broccoli* and winter *Greens* on all disposable vacancies. Sow *Spinach*, *Turnips*, *Endive*, *Lettuces*, and *Radishes* to maintain the successional supply. Plant *Leeks* in well-manured land.

FLOWER GARDEN.

As we may presume the principal planting-out for the season is over, and for which the late rains will be of much service in promoting a free start, the usual routine of pegging down plants intended to be kept dwarf, tying others up, and keeping the surface of the beds free from weeds until they are covered by the growing plants, will comprise

most of what is required for the next few weeks. In the meantime some attention must be paid to propagating various kinds of perennial plants of which a stock is required. Cuttings may be put in of Tea and China Roses, selecting wood of the present year when it becomes a little firm at the base. Roots, bulbs, &c., of Anemones, Tulips, Crocuses, Scillas, Fritillarias, &c., which have been out of the ground for some time to dry, should be properly labelled, and put by till the autumn, when they will be required to fill up their respective beds for spring flowering. Keep the smaller and seedling plants free from weeds, and lose no time in sowing perennial and biennial flower seeds for blooming next season. Quick and Privet hedges should be closely cut-in with the shears. Let them slope-in a little towards the top, which will give them a better appearance; but hedges of larger-leaved plants as Laurel, Turkey and Lucombe Oak, and Sweet Bay, must have the young wood cut back with the knife, as the shears would destroy the beauty of their leaves. Shrubs grown to embellish Italian and geometric gardens, terraces, &c., should now likewise be cut into the figures they are to assume; in many cases wires will be necessary to keep the branches in the proper places at first, when afterwards the knife and shears will suffice to keep them in proper form. Portugal Laurel, Cyprasses, Arbor Vitæs, Yews, Bays, and tree Box, are the plants most commonly employed for this purpose, and when cut into architectural figures are fine accompaniments of the above style of gardening. They should, however, be clipped in two or three times during the season, to preserve correctly the required outline. Flowering shrubs as they go out of bloom to have the dead flowers, &c., removed, and be slightly cut back. For the same reason remove the seed-pods from Rhododendrons, tree Pæonies, &c. These little attentions will be followed by an increased growth of the plant, and with the greater certainty of their blooming every season. Late-sown annuals should be thinned out as soon as they are well above ground, for if left to grow too thickly they spoil one another, and never make half the display plants do that are allowed plenty of space, and which are grown strongly from the first. Plants growing in baskets and vases to have a final stirring of the surface of the soil before it is entirely covered with foliage. Likewise put on a layer of moss to check evaporation, and thus save some labour in watering. On light dry soils American plants will be greatly benefited by a good soaking of water after flowering, and the finer specimens should be mulched to assist in keeping the roots moist during the growing season. Water Dahlias in dry weather; it will also be serviceable to mulch the surface of the soil with rotten manure Trap earwigs.

FRUIT GARDEN.

Peach trees will require repeated attention directed to the judicious regulation of the wood, with the view of maintaining the equilibrium of the tree. An undue growth of laterals should be suppressed, and the shoots regularly tacked to the wall, and the fruit exposed to the light. Trained Pears demand similar attention. Remove Raspberry suckers, four will be sufficient to remain. Strawberry runners will be found sufficiently advanced for layering.

GREENHOUSE AND CONSERVATORY.

Should the plant-structures require repairs or cleaning, the stock may be removed with greater safety at this than at any other period. It is injudicious to leave the completion of such work until late in the season. Enjoin care in watering. Some importance belongs to the due adjustment of the supply to meet the varying requirements of the plants. Attend to the propagation of Pelargoniums and herbaceous Calceolarias, and other half-hardy plants. Forward Chinese Primroses for winter blooming, and watch the general stock for autumn decoration. See that the Lilacs, Deutzias, and Provence Roses forced the preceding season are plunged and top-dressed. Propagate the Chinese Chrysanthemums for blooming in small pots. Go over the twiners in the conservatory frequently, and regulate the growth before the shoots get entangled; but avoid keeping them tied too closely, for they are never seen to advantage unless they are allowed to hang in their own natural and graceful manner. A number of hardwooded plants which were cut back some weeks since, will now have recovered themselves, and be commencing a fresh growth. This is

the proper time to shift into larger pots any plants requiring it. After potting keep the plants close for a few days, and syringe them daily, but avoid giving any more water to the roots than is sufficient to preserve the old ball moist. Mind the roots of the plant are well moistened before being potted. At this season when the plants in the conservatory are making their growth preparatory to blooming, it is of the greatest consequence that the border in which they are planted should be properly examined as to its humidity throughout, and receive, if necessary, a thorough soaking of weak liquid manure. This application should not be delayed too long; if applied late it might prolong the growth so much in the autumn as to prevent its getting ripened in due time, and hence the blooming of the plants would be injured. These remarks apply, of course, to those plants permanently planted out, such as Camellias, Oranges, climbers, &c.

STOVE.

The stock here will now be growing very rapidly, and must be afforded sufficient space to allow of the perfect development of the foliage, and the formation of compact, handsome specimens. The atmosphere of this house can hardly be kept too moist, and the plants should be sprinkled overhead morning and evening, and every available surface kept constantly moist. A slight shade will be necessary for tender plants in active growth, for a few hours on the forenoons of bright days; but this should be used as sparingly as is consistent with the perfect safety of the foliage. Plants that are known to suffer from the direct action of the sun's rays should be placed in a shady part of the house, or kept together at one end, where they can be shaded without interfering with the plants that require plenty of light. Mealy bug and thrips will require to be looked after here for some time to come, and the utmost diligence must be used to keep these pests in check.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

SOWED two rows of Peas. Planted out more Celery. Pricked out more winter stuff. We envy those who can plant out quarters at once, for we have to do the next best thing and must lift if possible with little balls as we get some ground cleared. The rains and the sewage together have made early Peas continue so long in full bearing, that we shall not be able to remove them for some time. Plants of Sangster's, turned out from being sown on turves, and which have been daily gathered from since the first days of June, are now nearly 6 feet high, and so loaded that people will not believe they have been gathered from at all. With plenty of nourishment and close picking much may be done in little room. Went over a piece of Dwarf Kidney Beans under protection, and picked off all the larger beans for the hall, as one pod with beans forming and swelling inside will more exhaust the plant than a dozen nice crisp ones in which no sign of the bean appears.

Staked Peas and Scarlet Runners, using for the latter the rough tops of some young larch trees, which we have kept several years for this purpose. This and spruce after the foliage has fallen are excellent for this purpose, and owing to the resin and turpentine which they contain, will last long after common pea-sticks from hazel, beech, hornbeam, &c., have rotted into dust. Twigs from these resinous trees answer well for the plants in the flower garden, and we prefer the spruce for bushiness and their lasting properties. Fresh twigs of larch—that is, those taken last winter, make also capital hair-pin pegs for the flower-garden. They are nipped off in bundles 6 or 7 inches long, are just cracked in the middle, and the two ends stuck in the ground over the shoot to be pegged down. Thinned Turnips, sowed succession of them and Radishes. Planted Cauliflower, watered that producing with manure water. Gave larger pots to Capsicums from which we expect ripe fruit for Cayenne pepper. Prepared Mushroom-bed in shed. Thinned out Tomatoes. Thinned and top-dressed Cucumbers in frames, which up to this time have done splendidly and as yet gave no signs of the Cucumber disease, which troubled us last season and for which we could find no remedy except fresh soil and frequent planting.

This disease for two years, showing itself in little brown spots on the leaf, and a guttering gumming of the fruit, showed itself on every member of the Cucumber family except Melons, which never were more healthy. In-doors and out of doors, by hot-water heat, and dung heat, and no heat at all, under hand-lights, and in the open air, Cucumbers and Vegetable Marrows suffered and in almost every variety of soil, and we failed to have good Cucumbers except by frequent planting. We were not at all troubled last year in the early part of the season. As yet we have seen no appearance of the evil, and we hope we shall escape the infliction. It was annoying to be scarce of Cucumbers when they could be bought for "two a-penny."

We have nearly a dozen of inquiries on this subject, and we say honestly to them all, that after trying all sorts of schemes we could not destroy the evil, and the safest plan is just to sow again whenever a trace of the disease appears. 'Grow the plants to a good size in pots, and destroy the old ones. Clean the place well and plant in fresh soil. What brings it we are quite unable to say, as in almost every conceivable position, Cucumbers were affected here after mid-summer last year, when they had borne only a short time and produced at first healthy fruit. Generally a bed of Cucumbers used to last the season, but they have not done so lately with us; but we hope that our beds will continue to produce as abundantly as they have done this season. If so, we shall be glad; but if we should be so fortunate, we freely confess that we shall be as unable to account for the continued success, as for the previous presence of disease, as the course of treatment is much the same as that followed for many years, when Cucumbers were such a matter of course as to give no trouble whatever except the routine of management.

FRUIT GARDEN.

Much the same as previous week. Plenty now to pick and choose from. Gave a little more water to British Queen Strawberries, where the crop was heavy. Hope to have drier weather for the other kinds to get them gathered. Raised Melons on flats to keep them from the soil, and thus prevent cracking. Gave a drier air to those ripening, so as to secure flavour by that and full sunshine. The shading of Melons is one cause of their inferior flavour. In managing Melons disbudding is better than pruning. The mode of disbudding and stopping which we consider most systematic and correct has been given several times already. Here we think it necessary to state a little fact in the way of caution. We have used bruised laurel leaves for destroying green fly and other insects. We tried it a short time ago on Cucumbers and Melons, where a little green fly showed itself. The leaves or young shoots of the laurel are very strong in prussic acid when bruised now, and, therefore, much fewer of them must be used than in winter and spring. In a two-light box of Cucumbers half a peck of these leaves, bruised, were placed in an open box, and they settled the insects without hurting the plants. When about the same quantity was placed in a bed of Melons the larger leaves were considerably injured, and had to be removed; and this also injured the fruit then set a little more. As we had others about the same stage we removed the fruit as well as the affected leaves, and allowed the young shoots to run again, which are now setting with young fruit. We have often found that Melon leaves are more sensitive to tobacco smoke than Cucumber leaves. The same seems to hold good with the fumes from laurel leaves. Such facts tell us to beware of strong doses of anything. We believe that the Melon leaves were dry.

We do not think we can give the *rationale* of the result, but we have seen the half of a house syringed before smoking with tobacco, and the other half left dry. Though both ends of the house were filled with similar plants, the syringed plants suffered considerably, whilst the dry plants were not the least injured. In places that can be at all shaded it is a good plan to give little air for twenty-four or thirty-six hours after smoking, and though the paths and the stages of the house are kept moist, no syringing until after that time should be given to the plants. Insects that are only sickly at first will die in such an atmosphere. If washed off and not killed by the fall they are refreshed by the water and the pure air near the floor, and will be able to crawl up again in

shoals. These may be some of the reasons why insects are found worse to destroy at some times than at others.

We are now getting *Cherries* out of doors in plenty, before we have finished with *Cherries* in pots in the orchard-house. The latter seem to be the best flavoured. A Cherry-house must be a fine sight. For early ones we would be disposed to have a house in two divisions; to set the fruit in the colder almost open house, and then take them to swell off where more heat could be given—even if that was by an earlier-shutting-up. We had *Cherries* by this means very early. A few *Plums* in pots will also come early so treated. When we fairly try *Apricots* in pots, we would treat early ones much the same. Neither they nor *Cherries* will stand a confined warm atmosphere in their earlier stages. With all this, however, and seeing anything but the impossible in the culture of fruit in pots, we by no means say a word as respects the economy of the thing. The watering alone will make a hole in the question of economies. For amateurs who do a good deal of the work themselves, and who have a pleasure in having a great deal in little room, we have no fears of the system going out of fashion.

In general, and in dry weather especially, kept the floor and stages pretty moist, except in the places where Grapes are ripe and ripening. This we consider a better plan in general than washing the *Vines* all over, until and even after the bunches are colouring. Unless the purest water can be obtained the Grapes are apt to be disfigured. We never can depend much on our water as to clearness and purity, and therefore we prefer that what the *Vines* do receive shall be pure, such as is raised by evaporation; and we like to see the dew drops hanging from the points of the leaves in a morning which they have condensed during the night. We generally give the *Vines* a good shake, as soon as the fruit is set, to get rid of the bloom; and then, generally, we syringe every part well with tepid water, the clearest we can get, to remove all remains of the bloom, and after that we syringe no more. With a little sulphur on the pipes, and the moisture on the paths, and a rather close atmosphere instead of a very airy one, we are seldom troubled with red spider; and we see little of thrips on the *Vines* since we gave up placing Azaleas under the *Vines*. If there was a single thrip on the Azaleas he would be sure to found a colony on the *Vines*.

It is a grand thing when plants are kept in their separate houses, instead of being forced to make every house an *omnium gatherum*, or a general receptacle. We never have a house for *Vines* alone, until the *Vines* are getting ripe. At all other times whenever a ray of light can be obtained, there are plants below for profit or pleasure.

A few of the brown beetle appeared in the Peach-house, from which we have been gathering some time, and these we were forced to squeeze and wash off. *Smoking* was out of the question, as it would have left its nauseous flavour with the fruit. This house was not smoked during the season. If a few green fly appeared they were rubbed off or washed, as the house until lately has been supplied with Strawberries on shelves, and after the fruit commences the second swelling a smoking with tobacco injures the flavour, unless, perhaps, for veteran chewers of the weed. Some time ago, we had nice-looking Keens' Seedling Strawberry sent to taste, and one tasting was enough. We could not make it out at all, until some close questioning brought out the fact, that a few days before the place had been smoked three nights running. The Strawberries might nearly as well have lain an hour in tobacco juice. We do not know any fruit that is not less or more affected by tobacco smoke, when the fruit is ripening. We recollect tasting a fine Melon with a peculiar custard flavour, which seemed to give a sort of piquancy to the natural aroma of the Melon, though a little more would have made the Melon disagreeable. We found out that just as the fruit was cracking its skin a little as it was ripening, some bruised Laurel leaves had been put in the frame to keep some green fly at bay. All fruit as it ripens should be kept in the purest air, and that air if possible drier than usual. Every thing uncleanly ought to be avoided. Some objections have been made to what we said the other week about washing Strawberries. All we shall say is, that if those who will take the trouble to grow Strawberries, will not take the trouble to keep them clean, they pretty well deserve to be choked with dirt. Even the grit would be preferable to fruit washed in a

pail not over-clean with hands not over-delicate, and then spread out to dry before going to table. What sort of flavour can they have after such sousing and washing, and the necessary accompaniments? for we maintain that where nothing is done to keep Strawberries clean, there will be no great particularity in the mode of cleaning them. One great advantage of growing small fruit, as Gooseberries, Currants, &c., on trellises, and elevated as dwarf standards is, that the fruit will always be clean. No spattering of mud on them after a shower. These things will be more thought of when quality as respects flavour shall be more considered than mere appearance, when fruit is sent to table to be eaten, instead of, as is now often the case, merely to be looked at. After using different coloured gravels and other materials as a substitute for flowers in beds, it would only be a step to paint wood and wax, in imitation of the best fruit for the ornamenting of the table. If for mere show they could be rendered as attractive as the realities.

We are informed that *artificial bouquets* are now taken to balls and routs, and that a favourite scent can at any time be thrown over them by touching a spring in a concealed bottle or reservoir. The huge size that bouquets are now getting—enough for a moderate-sized flower-bed—may force on the use of artificial flowers among those who feel compelled to follow the fashionable, and yet keenly study economics. After all, what great difference can there be in a lady holding a nosegay of artificial flowers in her hand, and carrying a sheaf of imitation of the real and unreal in her bonnet? For our sister flowers of humanity there is no flower we gardeners can cultivate that can be too good; but there is such a thing as gracefulness and beauty being so over-adorned that what is considered by many indispensable to be fashionable, is looked upon by those of more chaste and refined taste as nothing but deformity and vulgarity. With such variety of tastes it is a matter of gratitude that all may carry out their own peculiar views if they do not infringe on the rights of their neighbours.

ORNAMENTAL DEPARTMENT.

Here we have been very busy in potting, clearing, mowing, rolling, &c.; but on these, and especially potting and the summer treatment of plants, we shall have something to say next week.—R. F.

COVENT GARDEN MARKET.—JULY 2.

Of all out-door vegetables there is now an abundant supply; and of Pines, Grapes, Melons, Strawberries, the supply is fully equal to the demand. Peaches principally consist of Violette Haïme, Noblesse, and Royal George, the latter and Galande or Bellegarde being particularly fine. Some excellent Pigs are brought from Marseilles; and consignments from abroad continue to arrive, and consist of Victoria and Green Gage Plums, Carrots, Kidney Beans, Endive, Artichokes and Tomatoes. Common Cherries can now be obtained at from 3d. to 6d. per lb., but for those of the best quality former prices are still maintained. Cut flowers principally consist of Roses, Pelargoniums, Orchids, Stephanotis, Calceolarias, Sweet Peas, and Mignonette.

TO CORRESPONDENTS.

RUELLIA, LESCHENAUTIA, AND ERICA CULTURE (T. G.).—A cool greenhouse is the proper place for them, and the highest and most airy situation the structure affords. Sandy peat is the most suitable compost, good drainage being the key of good root-action. The soil should at all times be kept moist; too much moisture, however, is certain destruction to the roots, and a dry soil both to them and the plant. At all times, except in very frosty weather, they require fresh air continuously winter and summer, and should not be mixed with other plants which would rob them of light and air. They like a rather dry atmosphere, a close moist atmosphere being very injurious.

FOXGLOVE—GYPSUM (A. N. W.).—If cattle were to eat a large quantity of Foxglove it would be fatal to them, probably; but we believe they would not eat it unless starving. The residue after obtaining carbonic acid by pouring sulphuric acid upon whitening is gypsum, or Plaster of Paris (sulphate of lime), and has been applied beneficially to Clover, and as a top-dressing to lawns. On some soils it has been found beneficial when mixed with them previously to sowing Turnips and planting Potatoes. 3 cwt. of it per acre is sufficient.

SEEDLING CINERARIA CULTURE (A Young Gardener).—Pot them singly, when large enough to handle, in 48-sized pots, and place in a cold frame. Heat is ruinous to Cinerarias. When the pots are full of roots shift into 24's, and grow on in the frame as before, putting on the lights only during very wet weather, and in the early frosty nights of autumn. Remove the plants to the greenhouse in the beginning of October, and shift into 16's or 12's according as you wish to have the plants large or small. Keep near the glass in the coldest place, it cannot be too cool so long as frost is excluded, and give abundance of air at all times, except in frosty weather. Keep down the green fly by frequently fumigating with tobacco smoke. A compost of turfy loam one-half, and one-half leaf mould, and well-rotted manure in equal parts, is the most suitable compost.

VINES IN POTS (T. H. J.).—Keep the Vines in pots dry at the roots, but do not withhold water altogether, give only sufficient to maintain the leaves from flagging. If your Vines are trained so as to be near the glass, we advise you to let them remain there until the leaves have fallen; but if not in a situation where they receive abundance of light by close proximity to the glass, we advise you to have them placed there at once, and so get the wood hardened, or ripened, before you think of putting them outside. So long as the large leaves remain green the eye at their axil is not fully developed, nor can the wood be ripe, though it may be brown. Maintain a dry atmosphere by a gentle fire in cold moist weather, in the house from which the Grapes have been cut; give air day and night; remove most of the laterals, to admit air and light to the large leaves and wood, and about a fortnight cease firing altogether, and give all the air possible. The leaves will fall in due time. Bowood Muscat does well in the same house as Black Hamburg, but it should have the warmest situation.

HOYA CULTURE (M. H.).—As your plant grows well it cannot be for want of heat that it does not bloom. Is it shaded by climbers, and at a great distance from the light? If so, and we fear it is, place in a position where it will receive the full sun; and, to assist in ripening the wood, give little water at the root—in fact, let it become dry after August, and give no more moisture during winter than is sufficient to prevent the leaves drying or shrivelling up. We have one now, on the back wall of a viney, with more than five hundred bunches of bloom upon it, and upwards of fifty of its wax-like flowers in some of the bunches.

WELLINGTONIA GIGANTEA (Rusticus).—Instead of your Wellingtonia thriving we think it is growing very slowly. The plant may have been grown in a pot prior to its being planted out, which has been the ruin of many of our choicest Conifers. Pot culture gives the roots a corkscrew character, whereas they naturally ramify through the soil in all directions from the stem, and this prevents their taking hold freely of the soil after planting, and their growth is slow on account of the crooked channels by which the sap is transmitted to the part above ground. The roots, too, in consequence of their corkscrew character, are not enabled to take that firm hold of the soil which enables the trees to withstand the violence of winds, and they are sometimes blown over. The above may be one cause of yours not doing well, or it may be attributable to improper planting, as in a cold, wet, clayey soil, and on the level without any preparation. Our advice is: selecting a showery time in September, remove the turf for a space of 6 feet all round the tree. Have a cartload of moderately rich loam—if turf loam with an equal quantity of leaf mould intermixed, so much the better—in readiness, then take up the tree carefully with a ball if practicable, and dig the whole of surface from which the turf is removed one spit deep. Spread about half the cartload of fresh compost on the newly dug ground, and point it in with a fork. This done place the tree in the centre with the bottom of the ball upon the surface, and put fresh compost round the ball, so as to cover it an inch or two higher up than before, pressing the soil gently around the ball. Place the soil over the dug portion of the field, so as to slope from the tree down to the turf all round. Your tree will then stand on a gentle mound, flattened or dished at the top for about a yard wide, to hold water, of which give a good supply immediately after planting, and then relay the turf, which will not be sufficient to cover the little hillock, but will leave a space about 1 foot 6 inches wide all round the tree. The edges of the turf will form a dish very useful in supplying the tree with water about twice a-week in dry weather; but none will be needed afterwards, which will be the case if September be dry; but none will be needed after planting if the weather be at all wet and showery. Try this, and your tree will astonish you.

AGAPANTHES UMBELLATUS CULTURE (Idem).—Pot in a compost of turfy loam and leaf mould in April, and place in a light airy situation in a cool greenhouse. Water moderately after potting, but when the pots become filled with roots water abundantly from May until October, keeping rather dry at the roots at other times, but not so as to affect the foliage much. The plants may be placed out of doors in June, and returned to their winter quarters in October. Under this treatment they mostly flower in September, and when distributed in large clumps in vases, or tubs, on terraces, they have a fine appearance. Kept in the greenhouse continuously they usually bloom in May, sometimes in autumn, and occasionally at both periods.

CUT FLOWERS (R. S.).—A prize “for the best collection” is very indefinite. We suppose the judges will be influenced not only by the number of different kinds, but by the taste with which they are arranged; and here we cannot help you, unless we had the flowers before us.

VARIOUS (W. M.).—1. With the greater heat in sunshine in a curate's viney, there would be the greater cold in dull weather, because the accumulated heat would sooner radiate. The larger orchard-house would have the advantage of greater uniformity of temperature, being not so quickly heated nor so quickly cooled, and the comparative earliness of the two would depend more on circumstances and the management, than on the merits of the respective systems. 2, Common sashes, wide or narrow, may easily be made to fit to the ridge form, by placing them together at top, and a yard or more apart at the base in the shape of a triangle. 3, Your proposed plan of using your sashes over a sloping frame with the Vines underneath is an old and a good plan. We have seen hundreds of good bunches thus obtained. Vines were grown against a wall; the frames were moved along the walls, so that a fresh piece of the Vines was taken in every year. A rough hotbed of litter was made, the frame set over it, and the Vine stems introduced, either through holes in the back of the frame, or just amongst the dung beneath it. The steam did good at first. By the time the manure had become sweet the buds would be swelling, and the material somewhat consolidated. Then the surface was covered with slates, most likely painted with sulphur, and the Vine stems trained, say 10 inches above the slate. Air was duly attended to; and a warm dull day selected for thinning the Grapes. The same plan answers admirably, as in the curate's viney, without any fermenting material, but they will not come to maturity so early. The mere distance of the Vines from the slates, provided the sun strikes on the latter, is of less importance as respects earliness than careful attention to the early giving and the early taking away of air, so as to enclose the concentrated power of the sunbeams. 4. By increasing the height of your frame-house, so as to be able to walk underneath it and do the work standing, and having no slates, you would be no better off than in your orchard-house. But, without the slates, you may ripen good Grapes in such a place; and you would succeed all the better and earlier, if you had a floor or wall that, from its dark colour, would absorb heat in the early part of the season; and of a light colour, so as to reflect heat and light in the autumn. We only speak of the latter colour in such a raised house. In a frame we should dread burning from the white colour. 5. Orchard-houses are very much as they are managed. Good gardeners are loath to say "we cannot;" but no work has ever contained so many confessions of failures and disappointments, from head men in the profession, as this work does. We believe all our coadjutors act on the principle that a failure understood is as instructive as a success. It is folly to condemn wholesale what many succeed so well in; and our columns are as open to failures as to successes. Our own opinion is, that almost anything may be grown in a pot or tub; but that it can be so grown economically for general purposes is entirely another affair. The watering alone would make havoc in the profits, but that allowed, there can be little question as to obtaining crops. Of course, let them hang as they grow, and failure is certain. Most people are rather sanguine, buy a lot of cheap trees with unripened wood and obtain no fruit that will stand. Good folks should at least try trees next season that they have themselves looked over this season. 6, If you could tell the reason why your Peach and Apricot trees in pots, so full of bloom, dropped their fruit, that would be a gain to yourself, and to the profession generally. The mere fact of failure is less against a system than a fact of success is in its favour. It is just possible that, like spoiled children, your plants had too much attention. We should conclude the growth was rather vigorous. We hope to have a better account of these trees next year. No doubt you will succeed with Vines, either in boxes or planted out. We also believe you will succeed with Peach trees, if your enthusiasm points that way, even though you should somewhat diminish the attention for securing luxuriance, and give a little more to the hardening of the wood early in autumn.

FICUS ELASTICA (A Reader).—We do not notice anything the matter with the leaf enclosed, and think the leaves fall naturally. With the Bilbergia vitata the cause may also be the same—namely, the old parts decaying as new ones take the strength and vigour of the plant. Your plants, however, we fear, are too copiously syringed, and the sun's rays striking powerfully upon them cause the spotted appearance which the India-rubber leaf had.

ROSES ON THEIR OWN ROOTS (S.).—We are at a loss to account for your Madame Laffay not blooming. It is one of the freest-blooming amongst the Hybrid Perpetuals. 1, We have not found any of Hybrid Perpetuals shy bloomers on their own roots; generally the reverse. 2, Caroline de Sansal, Comte de Nanteuil, Baronne Prevost, Général Jacqueminot, Jules Margottin, Madame Vidot, William Jesse, Prince Léon, Sénateur Vaise, Princesse Matilde, Maréchal Vaillant, and Lord Raglan.

VINES IN POTS—ROSES (W. Treasure).—The best kinds of Grape Vines for you will be the Royal Muscadine and Black Hamburg—soil rich loam; pots not less than 16 inches across. The best plan would be to get fruiting-plants at once. The difficulty will be that, if you take a heavy crop from these pots, so as to be attractive in your windows, the plants will not do much good afterwards, and you must have a fresh supply. You can easily grow fresh plants, but the difficulty will be in getting the wood well ripened in the autumn, if you have not a wall to give them a good heat against it. Is there no means of planting Vines outside, so that you could take so many shoots inside the window every year, and save the trouble with the pots? The pots will keep best in winter in the cellar; the pots even then surrounded with litter a little moist, or moss, or anything of the kind. If your Roses make such good wood, merely nip the points off in the autumn, and bend the shoots a little in spring, and you will have plenty of Roses. Keep the same principle in view with your strong-growing young Roses. Keep them dryish in autumn, to ripen the wood well.

CAULIFLOWER PLANTS BLIND (T. W. U. R.).—We attribute this to some defect in the formation of the seed. That it is a defect of the seed we have no doubt; for such plants never exhibit any traces of a plumule or growing point beyond the seed-leaves and a few rough leaves, and the plants always show, even from the seed-leaf, the want of a centre, or that which is necessary to produce a head. We at one time were inclined to attribute it to the attack of some insect, which ate out the centre of the plant whilst young; but by minute inspection we could find no trace of such an occurrence, still much to confirm us in the opinion that the defect was due to the defective organisation of the seed in the pod. We never experienced any difference between sowing the seed in poor and in rich soil; and thick and thin sowings were alike affected as regards the number of blind plants. Seeds, too, from the same packet, sown in different places, were all alike barren, whilst those from another packet, under the same conditions, gave perfect plants.—G. A.

MILDREWED STRAWBERRY PLANTS (H. M. P.).—The Black Prince Strawberry plants, if the leaf sent is a good specimen, are eaten up with mildew, the result, we should say, of being grown thickly in the bed, and standing too long in the same ground. They may also have suffered by want of water. The partial shade, and extra manuring may be the cause in the younger (the two-year-old) rows. Have you examined the state of the roots? After the fine showers we were surprised to find heavy crops of British Queen not swelling so fast as expected, and we found the roots too dry for the crop. We would advise change of soil, fresh plants from another garden, and not excessive manuring. We cannot be certain as to the Strawberry you describe, but we have very little doubt that it was the Hautbois.

MIMULUS CUPREUS FLOWERS EATEN (S. E. H.).—Slugs will eat the flowers; but if you have made sure that there are none in your garden, it must be the earwigs. They will eat the flowers of nearly anything, and in all probability they are the cause. We never suffered from sparrows; but if they be the cause of the mischief, some strips of glass, suspended on black thread or worsted, and about a foot above the plants, will make the sparrows cautious about visiting the spot. Earwigs may be caught by setting a number of earwig traps, which are to be had of most seedsmen for a trifle; or bean-stalks, cut into five or six-inch lengths, and placed horizontally on the bed, will catch a goodly number. They should be daily examined, and the earwigs blown out and destroyed.

SEEDLING GERANIUM (M. A.).—It is pretty, but its value must be decided by the habit of the plant. If very dwarf it would be worth while to send a plant of it in a pot, when in bloom, to the Floral Committee of the Royal Horticultural Society. The petals of the French Pelargonium were all shed; and from a flower only it is not often that the name can be determined, the varieties are such legions.

PLUM LEAVES DISEASED (—).—They are infested with a parasitic fungus. It evidently commences growth within the tissue of the leaves. Its production of spores might be checked, perhaps, by dusting the leaves with flowers of sulphur. We would also, in the autumn, have the walls painted with some mixture of which sulphur formed an ingredient. Salt, sprinkled over the border in the spring, might also be beneficial.

CALCEOLARIAS DYING (A Constant Reader).—If your plants turned out in pots had been those only that died, we could most likely have hit upon the reason. If the pots were at all full of roots, and were turned out dry, and with the ball unruled, no amount of future watering would damp the bulk of the roots, and, when exposed to a bright sun, there would first be flagging and then death. Those lifted from beds are not so subject to these evils, but even these should be well watered before they are lifted. We have lost some plants in a row that we found, on examination, were lifted with balls, but in a dry state. The moisture given in such case went beyond the balls, but not through them. These are the only primary causes of failure we can think of at present. Where the ground is light and sandy, it should be well firmed against Calceolarias, and the surface merely left open. There is just one thing more as respects the layered Calceolarias—Was the layering done before the severe frosts in May? In "Doings of the Last Week," last year, it was shown that layered shoots would be injured, and upright ones would escape. Why should Calceolarias be layered? It is against their nature. If layered down at all, it is better to plant on the slope, instead of banding the stems afterwards. It is better, however, to let the plants grow upright in their natural position. Verbenas, and things of that kind, that root along their stems, are better pegged-down; but, in strong rich ground, they also bloom better if pegged or twiggled-up, instead of being pegged-down. It would be as well to nip-in the laterals of the Clematis. The best remedy for the fungus in the Melon-beds is to give several good waterings with lime water. That will destroy the spawn if anything will. If you had examined the soil before using it, you would most likely have detected the white threads of the spawn, which should have been picked out. We can believe that your Melons will be thrown up, for we once saw a stone pavement thrown about as if crowbars had been used, and the joints had been cemented too.

MILDEW ON ROSES (A Constant Reader).—We never before saw any Rose trees so severely mildewed as are yours. We can only add to our recommendation published last week, that we would dust all the leaves and branches thoroughly with flowers of sulphur. If the Roses are overshadowed by other trees, these ought to be thinned, so as to admit more light to the Roses.

PRESTWICK FLOWER SHOW (B.).—We are very glad it was so successful, but to report it is not permissible. There are hundreds like it—all admirable, all doing a large measure of good; and the doings of which we are requested to record. If we admitted one we could not exclude the others; and our columns would be too much occupied with details uninteresting to the generality of our readers.

CLAY FOR STRAWBERRY-BEDS ON LIGHT SOIL (Daniel Cartwright).—Add the lime to the clay before it is applied to the plot intended for Strawberries. Having the clay in readiness, and the lime fresh from the kiln, or unslacked, place a thin layer of lime, and put one of clay, double the thickness of the lime, upon it; then another layer of lime, more clay upon it, and so on, until the whole is formed into a heap 4 feet high, the outside of the heap being of clay. One ton of lime is sufficient for six of clay. The lime will heat the whole of the mass, and make the mineral ingredients of the clay more soluble. After the lime and clay has lain a week in the heap, it may be spread upon the plot of ground, and dug in. Another plan is to place the lime in heaps of about a bushel, and to cover these with the lumps of clay. In either case the lime must be sprinkled with water before covering with clay, if the last be dry; but, if it be wet, water is not necessary to cause the lime to fail. The compost thus formed should be applied to the ground before deluging rains fall upon the heap, and make so much mortar of it. Six inches of the compost, spread equally over the surface, and dug in, will be a good dressing.

HEDGE (A Subscriber).—We do not see in what way we have misunderstood you. Copper Beech is not so hardy as the common Beech, and does not form so good a hedge. If you want a hedge of low growth, nothing grows so fast as Privet; but if you want something better to attain a height of 10 feet or more, we know of nothing better than common Beech; and this we would plant along with the Copper Beech, or Purple, unless you prefer hedge but 6 feet high, then Privet would make a hedge sooner.

NAMES OF INSECTS (S. T.).—The cells found in the old post, surrounded with pieces of Rose leaves, are the cells of the Leaf-cutter Bee, Magachile centuncularis. There is a description and drawing of the insect in the first volume of our New Series.

VINE LEAVES (*M. T.*).—The roughness beneath the leaves never occurs on very vigorous Vines. It will not deteriorate the crop. Admit air very freely.

DESTROYING GREEN FLY ON PLANTS IN BLOOM (*Amateur*).—Fumigate the plants with tobacco smoke.

PEACH TREE INFESTED WITH SCALE (*A Constant Reader*).—You can do little towards destroying the pests that infest your trees now beyond dabbing the infected parts with gum water, made by dissolving 4 ozs. of gum arabic in a quart of cold soft water, applying it with a soft brush. In about a week after it is applied it should be washed off by spraying strongly with water at a temperature of 120°. After the leaves fall wash the trees with a solution of Gishurst compound at the strength of 8 ozs. to the gallon of soft water. Apply it with a brush, rubbing it well into the cracks and crevices of the old wood, being careful not to injure the young fruit-buds with the brush. They must, however, be coated with the solution.

CULTURE OF FOREST TREES (*Rusticus*).—“The Forester,” written by Mr. Brown, of Arniston, and published by Messrs. Blackwood, will give you every information.

NAMES OF PLANTS (*W. L.*).—1, *Styrax officinale*, Linn.; 2, *Chionanthus virginicus*, Linn., with terminal inflorescence; 3, *Sassafras officinale*, Ness; 4, apparently *Pinus uncinata*, but we cannot decide without seeing the cones; 5, *Chionanthus virginicus*, Linn., with axillary inflorescence; 6, *Rhododendron hirsutum*, Linn. (*L. C. Sheffield*).—1, *Symplocarpus racemosus*, Michx. It is not a “British plant” as supposed, but a native of North America, and has escaped from gardens in this country. 2, *Sagina procumbens*, L.; 3, *Carex remota*, L.; 4, *Veronica serpyllifolia*, L.; 5, *Arenaria tenuifolia*, L. (*F. S. B.*).—The two Ferns are: 1, *Pteris cretica*, L., var.; 2, *Adiantum hispidulum*, Sw.; and the flowering plants: 1, *Glaux maritima*, L.; 2, *Cynoglossum officinale*, L. The Moss we cannot name without a proper specimen in fruit. (*S. N. E.*).—1, *Adiantum capillus-Veneris*, L., var.; 2, *Asplenium fragrans*, Sw.; 3, *Onychium japonicum*, Vize; 4, *Erica Iribana*, Andr.; 5, *E. tricolor*, Don; 6, *E. ventricosa*, Thunb. (*A Constant Subscriber*).—1, *Adiantum pedatum*, L.; 2, *Polygonatum multiflorum*, L.; 3, *Lomaria spicant*, Desv.; 4, Not in a fit state to be named; 5, an *Anemone*, but the specimen is not sufficient to show which species. (*E. W.*).—1, *Hemerocallis flava*, L.; 2, *Spiraea filipendula*, L.; 3, cannot be named from such a scrap; 4, *Epilobium angustifolium*, L. (*A. I.*).—The plant with red flowers is *Callistemon lanceolatum*, D. C.; and the other *Pittosporum undulatum*. (*J. Nicholls*).—The flowering plant is *Spirea salicifolia*, L.; and the Fern, *Scolopendrium vulgare*, Sw. (*B. Warsteadi*).—The Vine leaves have a fungus upon them, but it is more connected with excessive luxuriance than any other cause. We cannot name the seed-pod with certainty. It appears to belong to a *Bignonia*, or something closely allied.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

JOTTINGS AT AN AGRICULTURAL SHOW.

THE county Agricultural Meeting was held this year at Mannerling Maudit, and being of the number of those who have nothing to do, I determined to go, and ordered my bed at the Angel. I arrived in the evening, and found the gateway full of hearty-looking men. As I belong to the northern division of the county, and the Show was held in the south, and most of those present were judges and local committee-men, and as I had only lately taken to agriculture (I now farm twenty acres, and have two cows, two horses, several pigs, and lots of poultry), I was unknown. I verily believe I work harder upon and think more of my farm of twenty acres than I did at my business when at the head of a firm in the city. My object, therefore, was to get into the thick of the learned in agriculture, and to store all I heard in my mind. My anxiety on this point may give you the origin of these notes. As the evening grew later, the Angel filled. Most of the visitors had friends in the town, and they dropped in one by one till the room was full.

My first note was that the conversation was confined to the subject for which all had met. There were plenty of exciting political topics, but they were not mentioned. One young man, who seemed to be “getting on,” introduced hunting, but the subject dropped. Another said something about the Malt-tax; even that found no seconder; but the merits of sheep and oxen, of a certain horse bred in that county, of a breed of pigs recently introduced, of the weight of roots, and the probable average of the wheat crop, were endless subjects. Later the Judges came in. They knew most of the company, and everybody knew them. They knew their work would be early, and they soon retired—I did the same; but my bed was over the sitting-room, and it was getting towards daybreak when the cessation of the noise below allowed me to go to sleep. It was evident the real agricultural element had long retired to rest, save a few young ones, and these joined to many of the loose fish of the town, treated the inmates of the house to hunting and Bacchanalian songs, varied with negro melodies, the instrumental part of the concert consisting of rapping to time with the knuckles on the table, and striking tumblers with spoons,

every man to his taste. On a fine morning in June, between two and three, there yet remained some finding pleasure in declaring they would not go till morning and daylight, both of which had arrived.

At this Show they follow the very objectionable plan of public judging, and this led me to notice the difference in the manners, habits, and characters of these gentlemen.

Being on the spot, and a member of the Society, I was enabled to get early admittance, before there were many people on the ground, and to notice all that interested me. The Judges were in sets of three for each department. First, the Demonstrative. This Judge rather prefers to have the public around him, or at least within sight. He attitudinises; he likes to prove the task is not an easy one; he likes three or four competitors brought out from their pens and put side by side. He is then in his glory. He walks round them; he handles them, he appeals to his colleagues. With his right leg thrown well out, his head and bust thrown back, he stretches out his hands and arms, the former palms uppermost, and then comes the music; he hears from the spectators, “Look at him!” “What pains he takes!” “First-rate Judge!” And if his colleagues are against him he leaves them “not in anger,” and walks towards the admiring spectators. It needs all the stern discipline of a poultry show to check the tendency to applaud. We have seen such a one have out a sheep between two rows of pens, and, after trying to impress its merits on his colleagues, at last kneel down to demonstrate the points he was describing.

The next is the Passive. He wishes to have no one present but the Judges; he speaks but seldom, when he does it is to the purpose. He rarely handles anything; he speaks almost in a whisper; he is a first-rate judge, and his colleagues know it. The spectators say, “they don’t think much of him.”

The third is the “Have-his-own-way” man. He walks along the pens or stalls, and, having made his survey, at once points to a pen of fowls, or to any animal or animals, and says, “This is my first.” It is useless to try and convince him he is wrong; he knows better; and he’ll stand there all day, or sleep there all night, but “that’s his first.” As for the others it’s all a parcel of stuff. No doubt the other Judges honestly mean well, but they are wrong; there isn’t a beast in the class fit to hold a candle to his. At last the two unite in deciding against him. Well, he’s beat, and he can’t help it, but he will say, and he don’t care who hears it, there never was a worse decision; he’d sooner have his choice than any other three beasts in the class.

These were the Judges, and I found them the same when I dined with them afterwards. There was no assumption of character, no acting. The first and third really believed it was one of the highest offices a man could fill. I did not envy them; but, as I was walking about unconcerned and they were still handling, I think they envied me.

Next I had to look at the public—I like to do so. The first who came in was one of the leading men of the place, but rather notorious for his love of money. He seems to wear the same clothes, in every particular, that he wore and that were worn fifty years ago—blue coat with metal buttons, buff waistcoat, and drab trousers. As he passed through the wicket, he displayed his card. “Wish for a catalogue, sir?” said a young man. “Of course I do—member and subscriber.” He took it. “Sixpence, sir.” “Nonsense, my good fellow—member and subscriber, I tell you.” “I have to pay for all, sir, and you must pay.” “Where is the Secretary?” asked the now irate man. “Sixpence for a trumpery catalogue! it is unbearable—hand always in one’s pocket—I won’t pay for it. Ah! there goes Jubbins, the Secretary. Here Jub, my dear fellow, tell this tiresome man I am a member and subscriber. He wants me to give sixpence for a trumpery catalogue.” “So you must.” “What! pay for a catalogue! Never! Here take it back, you man. Sixpence indeed, to me, a member and subscriber!” While I was walking about the Show, he borrowed mine three times, having mislaid his own.

Then I noticed a man to be met with everywhere. He pays his price for admission, he buys a catalogue, he takes every paper of every kind that is offered to him. He thanks the man who is working the machine, and who shows him the process of making a drain-tile. He had a try at a hydro-pult, but he was unfortunate, and discharged it full in the

face of the "rural" who was looking on. I was wondering whether he ever bought anything, when the question was solved for me by two men who were in attendance on their master at an implement stand. "The guv'nor did not make a customer of him, Jim." "No, I should think not; them civil fellows that say Thank ye, and admire everything, never buy."

Next, there was another class equally ubiquitous, young, well dressed, tolerably well informed, and rather fast; eccentric in his choice of neck-tie, and his jewellery. He was standing near the first-prize pen of very fat Pigs; some young ladies were opposite, and a very stout man was looking complacently at the swine. "The owner, I presume," said the young man. "Yes," said the farmer. "Things do well in your part." "Yes, not much the matter." He glanced across at the young ladies, and went on.

There was the important gent smoking a cigar placed in a case that was composed of two kittens playing with a small ball, which had a hollow in it to receive the end of the cigar. He had a neck-tie remarkable from appearing to have every shade and colour that could be got together, and fastened with a most elaborate ring. His conversation was that this Show was very well for a small thing, but they should see the Show at "Porsey," in France. He always went.

Then the ladies' man, wearing a straw hat surrounded by a dainty ribband, his open throat spanned by a diminutive collar, held in its place by a narrow blue tie, which was passed through a ring. "Ever and anon" he removed his hat to pass his fingers through his rather long and curling hair, and to show how accurately it was parted down the middle. He was surrounded by ladies who seemed much pleased with his answers to their many questions about stock. He wished he might never be smiled upon again if he knew anything about the animals; but he thought those things in the square dwellings formed of hurdles were baa lambs, and that great thing with horns was a moo cow, and so on.

We got tired of him and dropped on a man who was sure of nothing; the only answer to be had from him was, it might or it might not be. We asked him a question, which he answered in the affirmative, and then sent a friend on purpose, to whom he said, No, because the question leaned to that answer. He was delighted with the whole Show, which he declared to be marvellous.

Then the Lord-Burleigh man, who joins every party that is looking at anything in particular, and when appealed to or spoken to, either nods his head, or sapiently rolls it from side to side, and then passes on.

These all give way to the man who either follows his calling by being at the Show, or gleans the knowledge necessary to enable him to indulge a hobby, with the satisfaction of knowing he was doing good while he was indulging his fancy. I have always thought shows were most excellent things, and I have met with more common-sense men and conversation in a showyard, than I often have at an exhibition during the London season. Lately, I have seen your columns open to contributions that only bear on the pursuit: therefore, if you think fit, you can find a corner for one who sometimes thinks with—*PEN AND INK.*

JUDGES AT THE INTENDED POULTRY SHOW AT THE AGRICULTURAL HALL.

OBSERVING it stated in your last, that Mr. Hewitt is to be one of the Judges at the forthcoming Poultry Show at the Agricultural Hall, I beg to state that no such appointment has yet taken place, consequently your article and remarks are premature.—*EDWD. TUDMAN, an Hon. Sec. to Poultry Club.*

[We saw a letter from Mr. Tudman to Mr. Hewitt, dated June 20th, asking him to be "a Judge for the Club," and ending with this—"I know full well your determination of being free and unfettered, and, therefore, do not press upon you rules or anything of the kind for your guidance. All I now simply ask is, Will you act as a Judge for us? A large Show is about to take place under the management of the 'Poultry Club,' and we trust you will give us the benefit of your acknowledged ability, with another member or two of our

Club." To that Mr. Hewitt replied—"I can only assure you it will give me equal pleasure to officiate for the 'Poultry Club,' as for any other Committee of Management, the restrictions (as now, by you proposed), being withdrawn."

The above offer of a judgeship from the Club's Secretary and Mr. Hewitt's acceptance of the offer we considered conclusive.]

JOTTINGS ON DURDHAM DOWN.

"Tis first the true and then the beautiful,
Not first the beautiful and then the true."

SAYD I to myself while wending my way through, or rather past, busy Bristol to beautiful Clifton. Plenty of the true in black, narrow-streeted, St.-Mary-Redcliffe-shadowed Bristol, and still beautiful as ever stand out the town rocks of St. Vincent—there they are before me this bright shining Monday, June 13th. Now, I did not trust my reverend person to the jostlings sure to be met with on a busy day at the Bristol Station, but slipped out quietly at Keynsham, evidently to the wonder of the whole train. "Strange gentleman that not to be going to the Show!" The one porter at the little station was with difficulty prevailed upon to accept my ticket. The monstrous train at length rolled slowly on, and left me to go my own way. On, skirting pleasantly as I neared it, the great black city, missing all its horrors, and chuckling at my own escape and comparative freedom from trouble. Temple Street Station, well I know it on a busy day. Bristol roughs in a ring round; cabs running into omnibuses; omnibuses threatening cabs; wheels caught into wheels; your neighbour's cab horse putting his head into your cab and giving you a moist kiss (suggestive of glanders) on your right cheek, and you not at all inclined to offer him the other also. Then the narrow streets, with black artizans, and worn-looking, lack-lustre-eyed women gazing listlessly at one from every alley. Oh! this jolting Bristol may produce the best of floor-cloth, but it is not pleasant to be in danger of being floored. Oh! inodorous, dangerous, horrible streets, I have missed you all, and here I am on Durdham Down, raising my hat from my aching brow. I took three services yesterday, to enjoy the beautiful, ever-beautiful Clifton air, which, like the water of the Nile, no one tastes and forgets, for taste the air you verily do.

Two years ago I was present at the meeting of the Society at Wells; so, well remembering it, I determined to compare the two all through. At Wells the Exhibition ground was good enough, and there was a capital view from it of the fine Cathedral, and the finer Glastonbury Tor; but to Clifton must be given the palm. There was a wide carriage-approach, and the Down turf and soil made wet feet impossible. Straight to the poultry show. Now, at Wells there was but one over-crowded tent, with the poor Pigeons put above the fowls (surely the latter should have had the cockloft). Here the Pigeons were as well seen as the fowls. As I was staying in the neighbourhood for a few days, and attended the Show both on Monday and Wednesday, "doing it" fully, I am prepared to give a more decided opinion upon some points than I could have done had I been present only one day. Was, then, the poultry tent a chief or secondary object of attraction? On Monday with some 7000 people present at this Show, it was pleasantly full; on Wednesday, with 18,000 present, the poultry tents were full all day, one regular stream of people; and on Thursday, when 50,000 people were present in the grounds, thousands I am told never did, or could, see one pen of fowls. At all times the poultry tent was quite as crowded as the horticultural, and more crowded than the fine arts tent. And why? Because God's works are more loved than man's, and living creatures with their ever-changing posture and attitudes bring out fresh beauties, and people, therefore, love to go and see them again and again. Oh! ye expellers of the Crystal Palace, Clifton Show condemns you. There I saw prim quaker ladies, fast-going ladies, invalid ladies on wheel chairs, enjoying to the full a show of—cocks and hens. I saw there church dignitaries, one chaplain to the Queen at least, I ran my elbow into a magistrate's

"Fair round belly with good capon lined."

I trod upon the toes of a bishop's nephew, and all these well-bred people had come to see—cocks and hens, which none

but low folks ought to care about. Well, never mind, I will not be angry. On to the birds.

Spanish.—"Ah! Mr. Rodbard, in your old place—namely, the first!" While I was looking at that wonderful cock bird, a kindly little man with a tailor visage said—"Poor fellow! it's a pity you're blind." The white corrugated skin was regarded by my little friend as a deformity, doubtless. *Dorkings*.—Lady Holmesdale's were giants: indeed, their ancestors which Julius Cæsar ate were, I fancy, a trifle smaller; and those of which Sir John Falstaff partook at Justice Shallow's, were, perhaps, not so large either. Eight pens of White Dorking—very glad to see you, for you are the real original proper colour, and Mr. Clift, of Surrey, has kept up the fame of his county by taking first prize. *Cochins*, beautifully ugly as usual, and having no tails, must, on Lord Monboddo's theory, have more head, and, indeed, I think they had. The *Cuckoos* struck me as being very good. Next, *Game*, sixty pens in all, and, as a rule, what good pens! Mr. Fletcher, of Stoneclough, Manchester, I congratulate you upon your great success. Your first-prize Duckwing cock was, in my humble opinion, the most perfect bird I ever beheld, and wonderful was the condition in which he was shown. "Arn't he a pictur, Sir?" said a neighbour in fustian. "Never saw a picture equal to him, my friend," said I. Next, *Malays*, only three pens happily, their horrible ugliness increased by the bad feather in which they were in. They looked as if the cook had caught each, begun to pluck each, and had thrown down each in disgust, with "Drat the birds, they ain't worth plucking." Surely these horrible creatures ought to have been put in a dark corner; or they might at any rate have had a curtain hung in front of them, inscribed, "Malays, but not fit to be seen, the half dozen people in all England who admire these can inspect them after six o'clock." *Hamburgs* of all kinds good, but I thought the Spangled the best, and I was glad to see the too-much-neglected (in Wiltshire, certainly), Silver-spangled mustered strongly. *Polands*.—Mr. Edwards, of Lyndhurst, deservedly first, with a pair of the grand old Black and White Crests. May he breed many such. The "Any other variety class," always an interesting class, deserves a few words. *Brahmas* in abundance. What a pity they are not shown among the Cochins, as "Black-speckled Cochins." The Black Hamburgs have a very Spanish look, especially the hens. I fear Rose-combed Spanish would be the correct name. Just a word about the White Spanish pen marked "disqualified, cock's tail made up." They seem by the catalogue to belong to a lady, one I neither know nor know of; but in the spirit of that charity which hopeth all things, I will say that to my mind no deception was intended. The cock's tail was broken, very likely in the basket, and mended with cotton (this very injudicious), the mend was inches above the quill, and a child could see it. It needed not Mr. Hewitt's sharp and practised eyes. I pass over the sweepstakes, merely noticing Lady Holmesdale's monstrous Dorking cock. Really my lady you, slightly to alter Shakespeare, "Have supped full of prizes." Now for the pretty *Bantams*. The black cock shown by Mr. Davies, of Newport, was the best I had ever seen; and Mr. Forrest's pen of Duckwings, the best pen I had ever beheld, with only one fault, they were a little too large for my fancy. The *Turkeys* were good; but why those "highly commended" did not take the second prize is to me a marvel, as they were certainly, unless my eyes deceived me, much larger.

Last, but not in esteem, came the *Pigeons*, and these were generally excellent. Carriers a goodly row. I think Carrier breeders should beware of getting their birds too small. I like the robust look blended with the elegant, such as I used to see in birds twenty years ago. Tumblers with heads perfect in roundness. Powters large, but not in good trim, feeling, perhaps, their confinement. Runts, would there were more. These are the Dorkings of Pigeons, and ought to be made profitable. Jacobins, the first-prize a little too large according to my judgment; delicacy of appearance should never be separated from a Jacobin, which is the type of a refined lady, hence an approach to coarseness is clearly wrong. Fantails very good, though I scarcely liked the Turncrows in the second-prize. The character of the Fantail head is, I hold, injured by the turn crown. The first-prize was excellent, and the birds robust, which they

should be. Owls extremely good, neat, and clean. So also the Turbits, which were numerous. May they always be as they are—distinct sorts. Nuns, not so excellent; but Barbs a treat to see, so wide were they in the forehead, and good in all points. Dragons were numerous, and Mr. F. G. Stevens showed a Buff pair with very excellent points. The Trumpeters were good. The first-prize birds, black and demon-like, with huge wings to their legs resembling Lord Dundreary's whiskers enlarged. Archangels, a great many. Among the "Any new and distinct variety" class, were some nice birds which would have surprised the old fanciers. The Satins were certainly very pretty. Last of all came the poor "wild Hawk," very wild, and very out of place, beating with bloody beak the iron bars. Oh! cruel fate, not unlike that of Tantalus, so many Pigeons to see, and never a one to eat, not even a little Almond Tumbler to convert into a roller. Poor Hawk! The fowls soon got used to the Show, and grew happily excited; the Pigeons endured it, but each day the poor Hawk was wilder and more unhappy. May I never see in a poultry-yard or a poultry show another "wild Hawk."

Now, to finish these jottings, let me say that the birds seemed well fed and well cared for. Such care was shown, that if a cock disliked his wives he was removed to another pen. They were likewise well supplied with water. Where the birds have large rose-combs the triangular troughs need to be pushed in a long way. I could ask for no improvement except more space for the Turkeys. I fear their quills were bent, and they not wholly comfortable. Much did I enjoy the Show. "Be that a Duckwing, Sir?" said a countryman of a Pile cock, and I acted as his showman, and soon found I gathered an audience. Even the crow of the Cochins, that long, lengthened Alexandrine crow, seemed to be a novelty to some, and called forth now and then a wondering "Lor my!" May the Bath and West of England Committee have ever the success they had on Durdham Down is the wish of—WILTSHIRE RECTOR.

TURKEYS AT THE BATH AND WEST OF ENGLAND SOCIETY'S SHOW.

We feel greatly indebted for your notice of us as "one of the most popular portions" of the late show at Bristol. Doubtless such would have been the case could we have been seen there; but we were placed on the ground, and no more space afforded us than that occupied by a Bantam cock over our heads. We heard repeated inquiries amongst the crowd for the Turkeys, and we have generally much to say for ourselves; but where was the opportunity for display when each masculine was squeezed with his partner into a pen of $2\frac{1}{2}$ feet square?

May we entreat you to impress upon Committees of poultry shows, that when they invite giants to exhibit at their meetings the least they can do is to provide for their accommodation? We have the honour to subscribe ourselves your obedient servants.—CLASS 29.

DECLINE IN CHICKENS.

I AM happy to be able to give your correspondent "A. K. C." what I have found to be a sure cure for the croup in chickens, if this is the name of the complaint from which his suffered, as what they died from he does not distinctly state.

I have reared fifty-six Dorking chicks this spring. The three first broods were all attacked when about ten days old, and I was in despair. Having great experience in poultry-rearing like "A. K. C.", and finding all ordinary means fail, I doctor them as I should a human being with sore throat—viz., with sub-carbonate of ammonia, one tea-spoonful to a table-spoonful of water, and each chick had three or four drops at a time three or four times a-day. Every one recovered; but their fondness for me was turned into hatred, the remedy was so obnoxious to them.

As it is a certain cure, perhaps "A. K. C." will forgive this one bad effect. Soot is also a very good thing to put into their water.—A SUBSCRIBER.

[We think the disease for which our correspondent states

the remedy and calls the "croup," is that of decline and derangement of functions, to which chickens of a few weeks old are so liable, and drop their wings in that desponding mode which we have heard called "Putting on their Mourning Cloaks."]

I OBSERVED in your Journal of June 21st that your correspondent "A. K. C." complains of losing his Dorking chickens. I found great difficulty in rearing such from their being affected with drooping of the wings, after they were a week or ten days old, in the same manner as stated by "A. K. C."

I was recommended to try cow's liver boiled in water with a piece of soda the size of a walnut, and found it most beneficial. I have lost none of my chickens this year, although they began to show signs of drooping. The liver should be crumbled and given in their food.—H. A. F.

[Another correspondent recommends Baily's poultry pills.]

THE PRESENT POULTRY SEASON.

In the last Number of the "Poultry Chronicle" you ask poultry-keepers to favour you with their progress this season: if mine is worth inserting it is at your disposal.

I have a mixed stock, but the Cochinchin element predominates; and on the 29th of February I commenced the hatching season by setting thirteen Cochinchin eggs. This was followed after a few days' interval by other two being set. Out of the three lots my produce was two birds. Many of the eggs were filled, but the birds were dead. I attribute this unsatisfactory result to the cold weather then prevailing—cold enough in the south, but more so in Scotland. My hatching-boxes were placed outside, at the back of the garden wall, and covered on cold nights with matting. That plan succeeded well with me formerly; but this season's experience will lead me to be more careful, and place the boxes in a more sheltered situation in future.

After my three failures, however, I succeeded better. There was a fortnight's interval between the third and fourth sitting; and as by that time the season was farther advanced and the weather more moderate, I had no reason to complain of my success. From six to, in one case, fourteen chickens were the usual hatchings, and fine, strong, healthy birds. Of the fourteen lot the hen has brought up thirteen, one was accidentally killed by being trampled on. Of all I have hatched I have not lost one from disease; and I do not recollect in previous seasons having seen them so advanced at their age. I have a great respect for pure-bred fowls, but for usefulness find the cross-bred ones far excel them. The advantages they possess are that they arrive more quickly at maturity and have a hardier constitution; and these are advantages which those who look principally to their useful properties cannot afford to despise.

I was told some years ago, when beginning poultry-keeping, that every egg would cost me 2d. I have never found that to be the case, but, on the contrary, the eggs we sell pay for the food consumed, and we have the eggs and chickens used in the house for our trouble; and all that is necessary to secure this result is to give them personal and particular attention.—AN AMATEUR.

UNHOUSING BEES—PRICE OF HONEY.

On the 14th of May I hived a swarm and put a super on immediately; this they filled, and on the 8th of June they began to cluster. On the 18th of June I thought they would have taken flight. I took off the super, which was apparently full of honey, but which turned out to have some brood in a very forward state in the centre of it, and put on another. I should state the front of my bee-house is boarded up, and in consequence of the boards warping a little the bees can get into the house. On the 20th of June and following days much rain with a rather high wind prevented any chance of a swarm, so that thousands took possession of a corner of the bee-house adjoining their hive, and built a great deal of comb. What ought I to do therefore? for I

cannot fumigate them; the house, of course, not being sufficiently air-tight.

I have put on several glasses this year, but not one have the bees worked in, although each had a ventilator. I have put on three straw supers, but only the one above mentioned has been at all used. How do you account for it?

Once more: I find poor people cannot get more than 6d. a-pound for their honey here, however good it may be. Where is the best place, therefore, to send it?—DUMPLING.

[Put on your bee-dress and gloves, and after blowing a little smoke from the fumigating-tube amongst the combs built in the bee-house corner, cut them boldly out and brush off the bees with a feather. They will supply excellent decoy-combs for your glasses, the want of which is the most probable cause of failure. Messrs. Neighbour & Sons, 149, Regent Street, and 127, Holborn, give a fair price for honey according to quality.]

LIGURIANISING AN APIARY.

WOULD "B. & W." say how he keeps his Ligurian and black bees from crossing in the same apiary.—A. W.

[In reply to the above inquirer, "B. & W." would state that he has hitherto not attempted to keep the Liguriants from crossing with the black bees, knowing it would be futile. By getting rid of all his black bees this year, "B. & W." hopes another year that all the drones in his apiary will be pure Italians, be they the offspring of his original purely impregnated Italian queen, or of those he has bred from her, but which are all, probably, impregnated by black drones. If not, there is no trust to be placed in the doctrine of parthenogenesis, for "B. & W.'s" apiary is a considerable distance from any other.]

SUPERING.

I HAVE a stock of bees in the common old straw hive with hole at top. On the 19th of May last they threw off a first swarm; same evening placed a small straw-cap hive on old stock, expecting them to fill it; they will not work in it. Will you kindly inform me what I am to do to obtain honey from them this season without destroying the bees?

My first swarm, which came off the 19th May last, now show strong symptoms of swarming. Can I do anything to prevent it or let them do so? Most probably both the old stock and first swarm will throw off a small cast each if allowed to do so. What shall I do with them?—O. O.

[If you wished to prevent swarming altogether you should have put a full-sized super on the stock in April. After swarming a super of moderate size may be placed on the swarm, not on the old stock, and this will, probably, prevent the issue of a "maiden." If you get two casts you had better unite them at once.]

OUR LETTER BOX.

DUCKLINGS DYING (*Constant Reader*).—It has been a very bad Duck season, and they have been scarce in consequence. The complaints we have heard have been more about hatching than rearing. Whenever Ducks are out of condition, they show it by a film on the eye. They are subject to cramp and it is fatal to them. We have never known one to recover when it proceeds from illness; but where it is caused by roosting in a house with a brick, stone, or wooden floor, they often get well if they are removed from it. Give them some oats put in a pan or other vessel with gravel.

DORKING COCK BUMBLE-FOOTED (*Inquirer*).—The large lumps in the feet, and the swollen legs indicate, we are afraid, a bad case. Dorking fowls, from their great weight, and the fineness of their skin, are always liable, after two or three years, to become "bumble-footed;" but their doing so is not inevitable; and if they have low perches, and proper floors, with a grass run, they may, as we have often seen, remain clean-footed, even though five or six years old.

SMALL BANTAMS (*T. D.*).—Those who wish to keep their birds very small, generally breed them late, so as to rear them when the weather is getting colder. We know no food that prevents growth.

* **MOTHS IN CORN BIN** (*A. W.*).—Perhaps airing and turning the corn to prevent the moths breeding in it, and scalding the hoppers and corn boxes frequently, will prevent the evil.

BANISHING BEES (*Grateful Heart, Ipswich*).—We cannot tell you how to keep your neighbour's bees out of your garden.

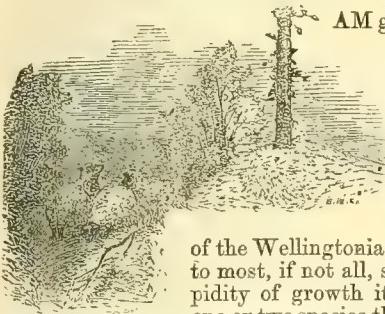

HORSES' MANGERS (*J. Friggs*).—We never heard of the machine.

WEEKLY CALENDAR.

Day of M'nth	Day of Week.	JULY 12-18, 1864.	Average Temperature near London.			Rain in last 37 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.	
			Day.	Night.	Mean.									
12	Tu	Buckwheat flowers.	75.4	50.7	63.0	12	59 af 3	12 af 8	6	1	17	11	20	194
13	W	Traveller's Joy flowers.	75.8	51.8	63.8	13	0	11	14	2	45	11	5	195
14	Th	Oat Grass ripe.	76.1	51.5	63.8	14	1	4	10	8	22	3	11	196
15	F	Hedge Parsley flowers.	75.8	50.3	63.1	20	2	4	9	8	28	4	23	197
16	S	White Poppy flowers.	75.8	50.1	63.0	15	4	4	8	8	29	5	7	198
17	SUN	8 SUNDAY AFTER TRINITY.	75.8	52.0	63.9	13	5	4	7	8	24	6	5	199
18	M	Eyebright flowers.	74.7	51.0	62.9	18	6	4	6	8	11	7	12	200

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 75.6°, and its night temperature 51.0°. The greatest heat was 93° on the 14th, 1847; and the lowest cold, 41°, on the 13th, 1840. The greatest fall of rain was 1.60 inch.

FAST-GROWING CONIFERS.

AM glad that the subject of remarkable Pinuses has attracted attention in your pages, and I willingly add my testimony to all that has been given as to the beauty

of the Wellingtonia and its adaptability to most, if not all, situations. For rapidity of growth it is second only to one or two species that I am acquainted with, and possibly local circumstances may have given them an advantage which they might not enjoy elsewhere. Mr. Ridgway has given, at page 434 of the last volume, very minute particulars respecting the growth of the fine specimen at Fairlawn; and I believe there is a similar fine tree at Redleaf, near Tunbridge. Both of these specimens are two years or more in advance of the best that we have here, and which was not planted out until January, 1859, when it was 1 foot 9 inches high. The wet season of 1860, and the severe winter which followed, did not affect it further than that it was a little browned on its eastern side, and the growth of 1861 was less than before or since. At Christmas, 1861, it was 6 feet 6 inches high. I have not its dimensions for the following year, but last Christmas it was 12 feet 11 inches in height, having made a growth of 6 feet 5 inches in two years, and a corresponding increase in diameter of stem. The growth of last year may be considered the more remarkable when I mention that last summer, about the beginning of June, a squirrel or some other animal nipped off the leader, cutting off about 9 inches. Such a disaster, I admit, alarmed me at the time; but such is the accommodating character of the tree that it speedily formed another, and now it is not easy to see that it had lost a leader. We may, however, justly conclude that but for this accident the tree might have been a foot higher; as it is, the fact of the tree so quickly forming another leader, and assuming its true conical outline again, is worth recording.

Rapid, sturdy, and symmetrical as the growth of the Wellingtonia is, it is equalled if not excelled in these respects by Cupressus macrocarpa or C. Lambertiana, for I believe the two are identical. A plant of this, about 18 inches high, was planted out in April, 1854; and in December, 1861, it was 21 feet high and 13 feet through at bottom, dense and bushy to the ground, and of the deepest green, on which the sharp winter of 1860-61 did not seem to make the slightest change. It is now about 28 feet high or more; but at the end of the growing season I will measure it. So rapid-growing a tree requires careful handling when young. A tree that has been some time in a pot, and has its roots so twisted that it is impossible to lay them out perfectly straight in planting, will only be a disappointment; for the tree being much more

dense in its habit than the Wellingtonia, it is much more exposed to the wind, and if it is not very carefully planted in the first instance it will not be able to resist the wind. I have known more than one tree 6 or 8 feet high blown down in consequence of the roots at the collar still retaining the coiled form which they took while they were confined in the pot, and therefore offering little resistance to the wind. The one above alluded to was well attended to, and has hitherto maintained its upright position.

Differing very considerably from either of the above in character, but I believe equal to them in rapidity of growth, is Thuja Lobbi, a most graceful Fern-looking tree of the Arbor Vitæ class; but it appears to have a greater disposition to make a tree, sending up a long slender leader several feet in advance of the side shoots, which also have a tendency to point upwards. A young plant of this species in a sheltered position has made a growth of 9 feet in the last two years, the tree being now 13 feet high. Thuja Lobbi promises to be second to none for beauty, and being perfectly hardy, must prove a great acquisition. Thuja gigantea and T. borealis also promise fairly, but have not the spiral form of T. Lobbi.

Mr. Palmer asks for the dimensions of other Pinuses as well as of the Wellingtonia. It would either be better to give the heights during the past winter or wait until the season's growth is completed; but it may interest him to know that Pinus excelsa is here considerably above 30 feet in height, and perhaps 35 feet, and about the same in diameter, while P. insignis will by the autumn be fast approaching 50 feet high, and upwards of 40 feet through; Cryptomeria japonica is 35 feet or more, beautifully tapering; Abies Smithiana about the same, and dense and compact; Picea pinsapo, the finest of all, is a perfect cone, about 26 feet high or more, and densely clothed to the ground. Our largest Deodar had to be taken down for the benefit of another tree, and I hardly think we have any exceeding 38 feet high. An Araucaria has, however, attained the height of about 30 feet, and is a finely-formed tree. My purpose, however, is not to go into details, but to invite those interested in arboriculture to report such particulars about their trees as cannot fail to be useful to all concerned. As Pinuses sometimes exhibit growth of more than ordinary dimensions in particular situations, an inquiry into the cause may throw much light on their cultivation. As an example of rapid growth in a species not generally supposed to be fast-growing, I may instance a Picea nobilis which we have here, that will by the end of the present growing season have increased its height 10 feet or more.

Before closing these stray notes on Conifers I may remark that I hope to hear of other instances of fast growth, and of remarkably fine trees. The genial climate of Devonshire doubtless favours the growth of trees of many kinds which cannot be expected to become equally fine in a cold bleak district, but we now and then meet with fine specimens where they are least expected. Many years ago I remarked one of the finest Araucarias that I ever met with in an old garden in Northumberland. I

think the same enclosure also contained a very good Deodar, but of this I am not certain. I may also mention that although I am tolerably well conversant with Mistletoe growing on various trees in Kent, I have never noticed so fine a specimen of this parasite as I observed on an old Apple tree near the Araucaria above alluded to.

I shall be glad to hear how the species I have referred to, as well as others, succeed, and no doubt planters will be interested to know in the autumn where the finest Wellingtonia is to be seen. Though the particulars given by Mr. Palmer as to the height of the best-known trees are interesting, I should not wonder if changes in their relative heights take place, and some outsider, not thought of, be found at the head of the list. The subject is one well worthy of attention, and at a future time I promise myself to go further into details than I can with any degree of accuracy do now, the middle of the growing season necessarily increasing the altitude of trees considerably; and it would be better for those who report during this progressive period to mention what their specimens were in the past winter.

J. ROBSON.

CULTIVATION OF THE MELON.

(Continued from page 475.)

SOIL.—Various descriptions of soil have been recommended for growing the Melon, but none is better than a strong rich loam with plenty of vegetable matter. The turf cut to form loam for the Melon should be taken 4 inches thick from a pasture which rests on a bed of clay; and if it can be had from the rich warped lands bordering rivers such is decidedly to be preferred. These turves should be laid in a heap for twelve months and turned over twice, and a bushel of soot mixed with every cartload at each turning, to enrich the compost and to make it obnoxious to wireworms and other pests. The whole chopped up with a spade makes a compost suitable for growing any kind of Melon; but it often happens that substitutes have to satisfy the cultivator. Road-scrapings form no bad substitute, but they should be taken from a road noted for being muddy; and the materials forming the road must not be limestone, for Melons will not thrive in limestone. The road-scrapings, mixed with an equal bulk of well-decomposed manure, and turned over occasionally for a year, make a very good compost for the Melon. The next best compost is ditch-cleanings turned over once or twice for a year; and if the cleanings are little besides clay mud mingled with tree leaves, so much the better. With the ordinary strong soil of gardens Melons may be grown very well; but light composts of whatever kind are valueless for Melon culture, yet they may be made to afford some fair fruit by adding an equal quantity of cowdung, and turning them over frequently so as to thoroughly incorporate the mass.

The above are all improved by being exposed to the influence of the atmosphere for a year. The compost should be made firm by treading or beating after being placed in the frame, in order to force the roots to run slowly through the soil, and give a stiff short-jointed growth.

PLANTING OUT.—The bed being covered with one of the composts, and all being in proper order as to bottom heat, sweetness of atmosphere, &c., select the pots that contain the shortest-jointed plants—that is, those of which the leaves are nearest to one another; and any that have lateral branches shooting from the neck of the plants are to be preferred to those that have none. Turning the pot upside down, and gently tapping the edge against the edge of the frame, the ball will come out entire. Plant this immediately in the centre of the cone, in the hole, so that the cone, after the plant is put in, may be 9 inches higher than the 3 inches of soil with which the bed is covered. The top of the cone or hillock should be rounded a little to hold water, and the soil having been pressed rather firmly round the ball, give a gentle watering to settle the earth about the roots, using water of the same temperature as the frame. In this manner plant the remainder of the lights. Two plants are sufficient for one light after March, but earlier in the season three are requisite as they do not grow so vigorously; but if they do, and there is any fear of the frame becoming too full, it is easier to cut a plant away than to plant to fill up the vacant space if a plant go off. Air will now be needed daily in mild and sunny weather, the amount being regulated by

a thermometer within the frame. For about a fortnight after planting the temperature should be 70° at night, and 65° afterwards; but when the fruit is ripening a temperature of 75° much improves the flavour, especially if accompanied by a corresponding dryness. Air should be admitted when the thermometer is at 80° if there is a prospect of more sun, and the frame should be closed with the thermometer indicating 85°.

ADMITTING AIR.—It is important to do this without causing draughts of cold air, and in the early stages, when the external air is cold and cutting, a thin mat or piece of taffy or hexagon netting placed over the openings will admit sufficient fresh air, and yet prevent the deleterious effects of cold. As the season advances air will be needed in larger quantities, regulating the time of opening and shutting up by the thermometer. Begin in the morning by opening the frame a little at the back, and then open wider as the heat increases. I know of no better contrivance for admitting air to frames than the notch system, in which a wedge is usually made out of an inch deal board, and cut with a saw to represent steps, the first of which is 1 inch wide and 1½ inch long, and cut slantingly, so that the lights can be elevated half an inch or an inch. The other notches are 1½ inch wide and long, and are generally four in number. The accompanying engraving (fig. 1) will show this useful contrivance, which is decidedly preferable to sliding the lights down, as this causes a current of air

at once by the escape of hot air at the back, and the ingress of cold in front to supply its place. This is extremely injurious to any plant, for by ventilation we seek to displace foul air and supply its place with fresh; but no one would seek to enjoy fresh air by opening two doors or windows from opposite points, and then sit down between the two in the full current of air. If such draughts are injurious to man they are equally so to vegetation. In giving air to Melons it is well to give a little air as early in the morning as safe, say a notch or half a notch as the case may be, and to increase the width of the opening as the sun increases in power during the forenoon, reducing the opening again in the afternoon in proportion to the decline of sun heat.

WATERING.—It is necessary that the plants be watered moderately when planted, for the moistness of the heat assists in keeping the soil moist—so much so, indeed, that early in the season very little water is required. Waterings, at first, must be given near the stems of the plants, but as the roots extend and reach the sides of the hillock more soil must be piled round it.

ADDING SOIL.—It should be placed in the frame twenty-four hours to get warmed before it is placed in contact with the roots. This fresh soil must afterwards be watered in place of that near the stem, for the Melon is at all times extremely susceptible of moisture at its neck and main branches. More soil must be added as the roots extend, so that about three earthings will be necessary at intervals of a fortnight, to cover the bed all over to a depth of 8 inches for early Melons. This will leave the stems slightly elevated, and so prevent water reaching the neck at the time of watering. It is imperative to keep the neck dry, or the plants will almost to a certainty canker there, and the result will be a loss of crop or immature badly flavoured fruit. For the second crop of Melons it is only necessary to earth the bed twice after planting, covering it to the extent of 10 inches; and for later crops it is not necessary to wait longer than a fortnight or three weeks before covering the bed with 1 foot of soil. In all cases the soil should be made firm, for Melons enjoy a firm strong soil. Water should be given once or twice a-week as the state of the soil may determine, it being essential to have the soil moist but never sodden, so that the plants may grow freely from the time the fruit appears up to the time of its maturation.

FRUIT SETTING.—A moist condition of the soil being necessary to insure free growth,—light, air, and temperature

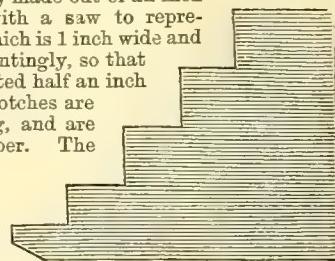

Fig. 1.

making that growth stiff or long-jointed, fruitful or barren, in proportion as they are judiciously or carelessly administered,—so is it desirable to have the soil in a healthy moist condition when the plants are in flower; at the same time, as is well known, the surface of the soil, at any rate the atmosphere, should be dry at the time of setting, otherwise the blooms set very indifferently. Though a rather drier state of the atmosphere assists in the process of fecundation, yet I am certain that the real cause of Melons being so uncertain in setting is not the moisture of the atmosphere, but a sluggish root-action owing to the bottom heat being slack; and in many cases the soil is dust dry, and can scarcely keep the leaves green, much less support a flower and swell the fruit. Keeping the frame close at the time of setting also prevents the pollen from being properly aired, which is a certain cause of not setting. I am not quite sure, but am inclined to think, that Melons and all other plants require quite as much moisture at the root at the time of flowering as at any other time; and though the pollen of any plant may be more freely distributed during dry weather, I am certain that a moderate degree of moisture is necessary to insure its perfection and consequent fertility. For a sure method of making Melons set, I know of nothing better than giving a good watering a day or two before the flowers are likely to open, to have the bottom heat brisk, and to admit abundance of fresh air, which cannot be given to Melons on dung-beds in dull weather unless the bottom heat be brisk. It is to want of air and active root-action that I attribute the difficulty experienced in getting Melons to set in frames. I may, however, be wrong; but I never experienced any difficulty in this respect in pits heated by tanks and hot-water pipes. While the fruit is setting no water should be given so as to wet the surface of the soil much; but if any be needed it should be supplied through drain-pipes with one end inserted in the soil to the depth of an inch. These, distributed 18 inches apart, will enable any one to water the bed without wetting the surface, for it is only necessary to fill the drain-pipes with water and leave it to sink into the soil. This is not a bad method of applying water to the roots after the vines fill the frame, especially in dull weather, when water on the stems is certain to cause "gout," if I may coin an expression, or a gummy exudation from the branches.

(To be continued.)

G. ABBEY.

ROYAL HORTICULTURAL SOCIETY'S SHOW.

JULY 6TH.

THIS, the last of the great summer shows, was well attended by exhibitors, by visitors interested in horticulture, and by many more belonging to neither class, who were drawn to it by the presence of their Royal Highnesses the Prince and Princess of Wales. Notwithstanding the large numbers who visited the Exhibition, at no time were the Exhibition tables overcrowded—a circumstance which can only be accounted for by the preponderance of the non-horticultural element, and the superior attractions for such of the fresh air and military bands. It must, however, be admitted that but for the flowers there was little to induce a prolonged stay in the arcades; for the dust was swept up by the ladies' dresses, and the stages for the plants were remarkable for their ugliness. They consisted of bare boards which had once been green, but had become of a nondescript hue between green and earth colour. How different this from the fresh green turf banks of the Regent's Park!

STOVE AND GREENHOUSE PLANTS.—These were for the most part the same as at the Royal Botanic Show on the previous Saturday. Among them were fine examples of *Ixoras alba* and *salicifolia*, *Kalosanths*, *Aphelexes*, *Vincas*, *Ericas*, *Hedaramas*, *Dracophyllum gracile*, *Allamandas*, *Dipladenias*, &c. *Pleroma elegans* was shown in fine condition in several collections. *Sollya linearis* with drooping blue flowers, and *Mussænda frondosa* with its large white calyx and small yellow flowers, were also very attractive. For twelve Mr. Fraser was first, Messrs. Lee second, Mr. Williams third; for nine, Mr. Peed first, Mr. Chilman second, Mr. May third, extra Mr. Wheeler; for six, Mr. Page second; for six (Nurserymen), Mr. Rhodes first, Messrs. A. Henderson second.

FINE-FOLIAGED AND VARIEGATED PLANTS.—Mr. Baines, gardener to H. Micholls, Esq., Bowden, took the first prize with a remarkably fine collection, of which the narrow-leaved variegated Croton, *Theophrasta imperialis*, a very large and fine *Gleichenia spelunca*, and *Alocasia metallica* with magnificent leaves, were the most noticeable. Messrs. Lee were second, having their large *Cordyline*, and fine specimens of *Neottopteris australasica*, *Cibotium princeps*, *Rhopala magnifica*, and other plants which have been noticed in previous reports. Variegated plants were confined to Caladiums and Ferns. Of the former, Mr. J. Veitch, of Chelsea, had the finest collection. It contained magnificent plants of *argyrates*, *Baraquinis*, *Houlletti*, *Troubetskoi*, *Belleymei*, *Lowii*, *Chantini*, and *regale*. Messrs. A. Henderson were second, their plants being also very large and fine. Their collection contained of kinds not already named, *pæcile*, *mirabile*, *Wighti* (very pretty), and *bicolor magnifica*. In variegated Ferns, Mr. Bull was first with *Pteris tricolor*, *argyraea sublobata*, and *albo-lineata angusta*. Mr. Young was second with *Pteris tricolor*, *argyraea*, and *cretica albo-lineata*.

FERNs AND LYCOPDS.—For twelve exotic species, Mr. Bull took the first prize with a fine collection, consisting of *Cyatheas*, *Dicksonias*, *Gleichenias*, *Cibotium princeps*, *Mariattia elegans*, *Microlepia platyphylla*, &c. Mr. Martin, gardener to J. Taylor, Esq., Woodberry Down, was second; and Mr. Young third. For British Ferns, Messrs. Ivory had first and third prizes, and Mr. Salter, of Hammersmith, the second, the collections of both containing many pretty forms. *Hymenophyllums* and *Trichomanes* were shown in good condition, especially *demicissum*, by Mr. Watson, St. Albans; Lycopods by Messrs. Higgs, Young, and Ingram, each of whom took a prize. Among the pans exhibited were fine examples of *Galeotti*, *Martensii*, *dumosa*, *umbrosa*, *microphylla*, *caesia*, and *apoda*.

ORCHIDS chiefly consisted of *Cattleyas*, *Vandas*, *Lælias*, *Ærides*, *Saccolabiums*, and *Oncidiuns*, many of them large specimens and in excellent bloom. Most of them, however, have been noticed in previous reports. Of *Ærides Larpentæ* two or three fine examples were shown. *Vanda teres* came from Mr. Williams; and from others *Oncidium divaricatum* with showy yellow, orange, and brown flowers, *Epidendrum crassifolium*, *Phajus albus*, very fresh and pretty, and *Ærides affine superbum* with seventeen spikes of bloom, large and small. Among *Anæctochils*, *Lowii* and *macodes petola* were well shown by Mr. A. Ingram, of Highgrove, who had first prize in that class.

The prizes awarded were:—For *Ærides*, &c., Mr. Baker first, Mr. Milford second; for *Cattleyas* and *Lælias*, Mr. Milford first, Mr. Baker second; for nine Orchids (Amateurs), Mr. Baker first, Mr. Milford second, Mr. Penny third; for nine (Nurserymen), Mr. Williams first, Mr. Parker second, Mr. Woolley third; for six, Mr. Wiggins first, Mr. Baker second, Mr. Page third.

PELARGONIUMS.—Mr. Bailey, Shardeloes, was, as usual, first in the Amateurs' Class. His plants consisted of *Lady Canning*, very fine; *Lord Clyde*; *Sir C. Campbell*, very large and profusely covered with bloom; *Desdemona*; *Etna*; and *John Leech*. Mr. Wiggins was second, *Maid of Honour*, *Kettledrum*, and *Regina formosa* being the best. In the Nurserymen's Class, Messrs. Dobson & Son were first, *Caractacus*, *Queen of England*, and *Lord Clyde* were the most noticeable; and Mr. Fraser second. In Fancies, Mr. Bailey was again first with fine plants, but not equal to those exhibited a month ago. The varieties were *Madame Rougière*, *Ellen Beck*, *Edith*, *Delicatum*, *Princess Royal*, and *Queen of the Valley*. Mr. Shrimpton, gardener to M^ss. Doxat, Putney Heath, was second; his *Roi des Fantaisies*, *Cloth of Silver*, and *Lady Craven* were very good.

Scarlet Pelargoniums, for which there were several classes, were a new feature, and one which promised to become very interesting and instructive. When further experience shall have been gained in the exhibition of these plants improvements will no doubt suggest themselves from time to time. For twelve distinct kinds, of any colour, *zonale* or plain-leaved, Mr. Fraser was first. Among the best were *Virgo Marie*, a beautiful white; *Leoni*, salmon; *Comte de Morny*, *Woodwardiana*, rosy carmine; *Madame Vaucher*, and *Rose Rendatier*, bright rose. Mr. Salter was second; *Helen Lindsay*, *Amelia Griseau*, and *Merrimac*, the latter with an immense truss, being particularly good. *Rubens*, a fine

salmon rose, came from Mr. Duke, Finchley, who was first for six.

Of the variegated-leaved kinds the best of those shown were Mrs. Pollock, Mountain of Snow, with pure white margin; Golden Vase, fine golden foliage. Mr. Fraser had the first prize in this class, and also in that for six scarlets; of these Martin Gireau and Attraction were very fine.

In Nosegays Mr. Salter was first. Model Nosegay, pink, Lord Palmerston, and Merrimac were fine.

MISCELLANEOUS.—Under this head it will be most convenient to group the remaining classes. Mr. Rhodes had a first prize for Heaths, of which amabilis, Paxtoni, and Fairreana were excellent. Mr. Watson, Clapham Park, had a similar award for Disa grandiflora and its variety superba, the bright scarlet blooms of which were very striking. Mr. McLellan, Barnet, exhibited some large and well-grown Begonias; Mr. Baines, Sarracenia and Anæctochilus Lowii in fine condition; Mr. Higgs, Putney Heath, three standard Fuchsias about 10 feet in height, and in excellent bloom; Mr. Collins, gardener to Major R. Trevor Clarke, Cotton, Tea, and Coffee plants; Mr. Bull, Green and Black Tea, also a collection of medicinal and officinal plants, such as Vanilla, Cotton, Ginger, Quassia, Pepper, &c., under their scientific and popular names. Mr. Bull and Mr. Williams also contributed collections of their new plants, most of which have been previously noticed, and others that will be referred to in our Floral Committee report. Mr. Salter had a dwarf Sedum, which is used with good effect as an edging at his nursery at Hammersmith; Messrs. Veitch, Lilium auratum, and their fine white Lapageria alba, also a collection of garden Turnips; and Messrs. E. G. Henderson, plants with ornamental foliage for the summer decoration of flower gardens. Stands of cut flowers, consisting of Carnations, Pinks, Picotees, and Pansies, were sent by Messrs. Turner, Hooper, and Weymouth. Roses were shown in good condition by Mr. Turner and Messrs. Paul & Son; and, finally, hanging-baskets, tastefully filled, by Mr. Williams, and A. Henderson and Co.; and plant cases and ornamental stands by Messrs. Barr & Sugden. Numerous prizes having been awarded for the various objects above enumerated, we must refer to the prize list for the names of those who were successful in taking them.

FRUIT.

The show of Fruit was very limited in extent, though the quality of that exhibited was good. When one calls to mind the palmy days of Chiswick when a hundred Pines were staged in one day, it looks something like retrogression to find only fourteen. The Grapes and Strawberries were finer than in the old times, but the best of the Peaches and Nectarines were nothing extraordinary.

Of Pines the best Cayenne came from Mr. A. Henderson, one of the Smooth-leaved variety. Mr. Brown was second with a Prickly Cayenne of 5 lbs. In Queens the best came from Mr. Grant, Finchley; Mr. Cawkill, and Mr. A. Henderson. Mr. Hannan and Mr. Bailey were first in the Any variety Class, the former with a Providence, the latter with an Envile, very fine. Mr. Kerfoot was second with Black Prince, weighing 9 lbs. 2 ozs., and third with a New Providence of 8½ lbs.

In Grapes the best Black Hamburgs came from Mr. Meredith and Mr. Petch, and very good they were; Mr. Sawkins was second, Mr. A. Henderson third. Mr. Meredith also had a first prize for Black Frontignan. In the class for Any Black variety Mr. Hill was first with his enormous bunches of Black Prince, Mr. Cross second with fine bunches of the same kind, Mr. Brown third.

In Muscots Mr. Sage stood first, Mr. Turner second, Mr. Embrey third. Buckland Sweetwater from Mr. Hill, the three bunches weighing 6 lbs. 3 ozs., was first in the class for that variety, Mr. Goldsmith being second. The best Golden Hamburgs came from Mr. C. Smith, Norwood, the bunches and berries large; Mr. Bain was second. In Any White kind long bunches of Chaptal, from Mr. A. Henderson, were first; Canon Hall Muscat, from Mr. Embrey, being second; and Foster's Seedling, from Mr. Meredith, third.

In Noblesse Peaches Mr. Tillery, Welbeck, was first, Mr. McLellan second; in Violette Hâtive, Mr. Sawkins first, Mr. Sage second, and Mr. Brown third, the fruit of all being fine; in Grosse Mignonne Mr. Robinson, gardener to R. Benyon, Esq., M.P., was first, Mr. Tillery second.

In Nectarines finely ripened Pitmaston Orange came from Mr. Cross, and highly coloured fruit from Mr. Brown, who was second; and in Elrige Mr. Cross, and Mr. Wills, Oulton Park, were first with excellent fruit of that variety,

The best Figs were Brown Turkey from Mr. Robinson and Mr. A. Henderson.

In Cherries Black Tartarian, very fine, from Mr. Turner, were first; Elton, from Mr. Widdowson, second; Black Tartarian, from Mr. Sawkins, third.

Strawberries generally were very good. In single dishes Mr. Widdowson was first with Admiral Dundas; Mr. Budd, Cobham Hall, second with Empress Eugénie; Mr. Kaile third with Admiral Dundas, one berry of which was of remarkable size and about 2 ozs. in weight; and Mr. Beasley, Twyford Abbey, had an equal third prize for Sir Harry. In six dishes Mr. Bailey was first with Filbert Pine, Oscar, Bictom Pine (a large white variety), Sir C. Napier, Wonderful, and Admiral Dundas, all of which were large and fine. Mr. Widdowson was second, Mr. Budd third.

Melons were not numerous. The best Green-fleshed was Oscar, from Mr. Bailey; and in the Scarlet Class Windsor Prize, from Mr. Goldsmith, was first.

Of Miscellaneous Objects, excellent Barrington Peaches were shown by Mr. Petch; very large and fine Brunswick Figs by Mr. Robinson; Vines in pots by Messrs. Lane and Son and Mr. Standish; Orchard-house trees in fine bearing, consisting of Peaches, Nectarines, and Plums, by Mr. Cocks, Clapham Park, and Messrs. Lane, the latter also having a collection of Apples, Pears, Cherries, Figs, &c.; Orange trees by Mr. Higgs, gardener to Mrs. Barchard; Strawberries in pots by Mr. Turner; Raspberries by Mr. Young, Highgate, and Mr. Sawkins; and good Grizzly Frontignan Grapes by Mr. Beasley.

FLORAL COMMITTEE, JULY 6TH.—One of the most beautiful of the Exhibitions of the season was held in the Society's Gardens, South Kensington, on this day. The introduction of prizes for collections of Scarlet Pelargoniums promises to be a success, judging from the several excellent collections brought forward for competition. Next year we hope to see many more exhibitors in this class. Several certificates were awarded by the Sub-Committee for examining new plants. Mr. Veitch, of Chelsea, received a first-class certificate for *Quercus* sp. *nova*, from Japan; and a commendation for *Linum Chamissonis*. Messrs. Ivory, Dorking, had a first-class certificate for *Polypodium vulgare pulcherrimum*, and *Polystichum aculeatum acrocladon*. Messrs. Jackman and Son, of Woking, had *Clematis viticella pallida*, new in shade of colour, pale pink, fine form—second-class certificate; and *Clematis viticella Mooreana*—commendation. J. Day, Esq., Tottenham, sent *Polychilus cornu-cervi*, a small-flowering Orchid, for which he received a commendation. From Mr. Bull, Chelsea, came *Cypripedium Hookeri*, *Ophioglossum palmatum*, and *Salpiclæna volubilis*, all of which received first-class certificates; also, *Pandanus Blancoi*, which was awarded a second-class certificate. Mr. Watson, St. Albans, sent *Astelia bivittata*, a graceful foliaged plant—commendation; Messrs. A. Henderson, *Gardenia variegata floribunda*—first-class certificate; Mr. Williams, Holloway, *Erica Lindleyana*—first-class certificate; *Dendrobium Moulmeinense*—first-class certificate; *Beaucarnea* species—first-class certificate; *Nidularia Innocentii*—first-class certificate. Mr. Baines, gardener to H. L. Micholls, Esq., Bowden, sent an *Ixora*, from Moulmein, which received a commendation. *Anthurium* sp., from the Society's Garden at Chiswick, a plant sent home by Mr. Weir, had a second-class certificate; it is a handsome Caladium-like-foliaged plant.

Among the florists' flowers but few certificates were awarded. Messrs. Smith, Dulwich, sent seedling Scarlet Pelargoniums *Pactolus*, *Model*, *Bright Eye*, *Princess Alice*, *Mary Ann*, in no way improvements on older sorts; also *Princess Mary*, a handsome variegated seedling, but not equal in foliage to many others. Mr. Watson, St. Albans, had *Calceolaria Beauty of Herts*, light orange brown, like Kentish Hero, of dwarf habit, free flowering, and a useful bedding variety—second-class certificate; *Calceolaria General Tom Thumb*, very dwarf, compact habit, with small bright yellow flowers, very free flowering—this also received a second-class certificate as a good variety for edging purposes. Mr. Salter, Hammersmith, sent a seedling Scarlet

Pelargonium Mr. G. Natchet, bright scarlet; fine bold truss of good compact form, thrown well above the zonate foliage: this will make a fine specimen plant: it received a second-class certificate. Scarlet Pelargonium *Ornement de Massifs* also came from Mr. Salter. It was an imported variety; the flowers bad in form, but novel in colour, shaded purple and carmine. It was commended as a decorative plant and useful flower for hybridising. If its colour could be secured in a flower of perfect form and good substance, which doubtless will be done, something beautiful and novel would be the result. Messrs. Downie, Laird, & Laing sent Scarlet Pelargonium *Golden Sceptre*, one of the innumerable varieties of Mrs. Milford. Mr. Wills, Oulton Park, sent Verbena *Ariel* and *Verbena Helena*; Messrs. E. G. Henderson, Wellington Road, Fuchsia *Lucrezia Borgia*, a large-flowering kind with expanded corolla, light red broadly striped with purple, bright red sepals—first-class certificate; Fuchsia *Sunshine*, crimson sepals, with pale lavender corolla; Fuchsia *Don Giovanni*, pale crimson sepals, with greyish expanding corolla; Oberon, reflexed crimson sepals, dark corolla; Charming, very much resembling Crimoline; Il Trovatore, white waxy sepals, rosy corolla edged with carmine; Verbena *Velvet Cushion*, noticed last week; Petunia *Cinderella*, semi-double greyish-veined flower; Petunia *Princess of Wales*, semi-double, pure white striped with mauve. Messrs. E. G. Henderson also sent a collection of their beautifully variegated-foliaged seedlings, many of which had been seen before, and received certificates.

Mr. G. Lowe, Beeston, had a very beautiful collection of cut Show and Fancy Pansies; Mr. Hally, Blackheath, Scarlet Pelargonium *Monitor*, of the Marbled section, with zonate foliage; Mr. Keeler, two seedling Scarlet Pelargoniums—Noble, a fine truss, with zonate foliage, and *Alba floribunda*, very similar to the former, perhaps more abundant in producing its trusses—both good flowers, but not superior or equal to Madame Vaucher or *Virgo Marie*. From Mr. Turner, Slough, came Picotee Princess of Wales, white ground, light delicate purple edge, fine petals, a most beautiful variety—first-class certificate; and from Mr. Vocknies Glloxinia *Princess Alexandra*. Mr. Hooper, Bath, sent seedling Pink British Queen; seedling Carnation Duke of Cambridge, rose flake, coarse flower; Pansy Snowball, pure white, with dark centre, a very superior and distinct variety—first-class certificate; Pansy Yellow Beauty; and Perfect Model, dark purple. Among other Pansies in the stand we noticed Bob as a very fine flower, dark maroon upper petals, yellow ground, good eye, deep belt, fine form; and Harry, dark purple upper petals, white ground, good eye, belted with purple, a very fine flower.

FRUIT COMMITTEE (G. F. Wilson, Esq., in the chair).—There were exhibited three excellent bunches of the Duchess of Buccleuch Grape from Mr. Thomson, of Dalkeith. This, which has already had a first-class certificate awarded to it, was in excellent condition, and, for the produce of a pot Vine, the bunches were unusually large, and the flavour exquisite.

Mr. Turner, of Slough, exhibited a seedling Strawberry called Sir Joseph Paxton. It is not one of those soft, pappy, fluted, cockscomb-shaped sorts, of which we now have so many, but a handsome and regularly-shaped ovate fruit, with a solid firm flesh, of a rich flavour, reminding one of that of the Hautbois. It was awarded a first-class certificate.

Mr. Ward, of Oxford, sent a seedling Strawberry which seemed, from its colour, as if it had a dash of the Black Strawberry in its breed, but it was not sufficiently rich in flavour to command an award.

A Black Grape from Oran was exhibited by Mr. J. G. Cocks, gardener to J. Cundell, Esq., Clapham Park. The berries were rather large, and hammered in an extraordinary way; but the flesh was hard, hollow, and flavourless, as many of those African and Asian Grapes are.

DEATH OF MR. DANIEL FERGUSON.—Mr. Ferguson, Curator of the Royal Botanic Garden, Belfast, died there on the 5th instant, aged sixty-two. He was a native of Perthshire, and was for a long time foreman of the Glasgow Botanic Garden, at which place he assisted in getting up specimens, &c., for Sir Wm. Hooker's (then Dr. Hooker) botanical lectures, and on whose recommendation he was

appointed to the curatorship of the Belfast garden twenty-eight years ago. He was well known in Ireland as a landscape gardener, and was very much employed in the north. His decease will be heard with regret by many; for he was not only able in his profession, but kind, courteous, and honourable. We are glad to hear that the Directors have signified their intention of appointing as his successor his son Mr. W. Hooker Ferguson; for his successor has been trained in the gardens under his father, and is of acknowledged high attainments, not only as a botanist, but as a cultivator.

THE ROYAL BOTANIC SOCIETY'S SHOW.

(Concluded from page 6.)

HEATHS were in great perfection. Among them were some splendid plants of *Parmentieri rosea*, *ventricosa Bothwelliana*, *obbata*, *Savilleana*, and *Fairreana*. The last-named, also *nobilis* and *Paxtoni*, were very fine in Mr. Rhodes's collection, which took the first prize in the Nurserymen's Class for ten, Messrs. Jackson & Son being second, and Mr. Baxendine, Guildford, third. In the Amateurs' Class for eight Mr. Peed was first, Mr. Wheeler second, Mr. Page third, and extra prizes were awarded to Mr. Chilman and Mr. May.

FUCHSIAS.—Of these several collections were shown in excellent condition. Rose of Castille, Lord Elcho, Madame Cornelissen, Fair Oriana, Souvenir de Chiswick, Fairest of the Fair, and Senator were the leading varieties. Mr. Cannell was first; Mr. Cross, second; Mr. Weston, third; Mr. Hayes, fourth.

PELARGONIUMS, although less numerous than at the previous Show, and not equal in size and profusion of bloom to the enormous plants then exhibited, were, nevertheless, very good, especially those from Messrs. Dobson, Mr. Fraser, and Mr. Bailey. Queen of Whites, white spotted with carmine, was very attractive; Lord Clyde and Conflagration were very striking from their rich glowing colour. Of Desdemona, Etna, and Sir Colin Campbell splendid plants were shown; Sanspareil, Perdita, Illuminator, and Empress Eugénie being also fine. For twelve (Nurserymen), Messrs. Dobson and Sons were first, Mr. Fraser second; for ten, Mr. Bailey first, Mr. Wiggins second; for plants of large size, Mr. Bailey first.

There was in addition a class for new Pelargoniums sent out in 1861 and 1862. In this the first prize was awarded to Mr. Bailey for Beacon, Pericles, Regina formosa, Landseer, Royalty, and Royal Albert; and Mr. Fraser took the second. But the best collection in the opinion of the Judges was that sent by Mr. Wiggins, of Isleworth, but which was disqualified for not being in accordance with the rules, there being varieties more recent than the years named. They consisted of Eurydice, white, with deep crimson upper petal and light edge; Royal Albert, rose, white centre, large dark blotch; Paris, rosy pink, maroon top; Diana; Maid of Honour, a very pleasing lilac; and Regina formosa.

In Fancies, Mr. Fraser was first in the Nurserymen's Class; and Mr. Bailey first, and Mr. Shrimpton second, in that for Amateurs. Cloth of Silver and Delicatum among light varieties were very beautiful and in profuse bloom; Ellen Beck, Roi des Fantaisies, Princess Royal, Sarah Turner, and Lady Craven were also sent in fine condition.

Of Scarlet Pelargoniums large plants were shown by Messrs. Catlin, Pettit, Duke, and Windsor, who each received prizes in the order in which they are named. Some of the plants, however, had their trusses tied down in a very objectionable manner. Of the varieties shown, Vivid was perfectly dazzling; David Manning had large bright flowers; Madame Vaucher, though not in full bloom, was evidently the best of the whites.

CUT FLOWERS, consisting of Roses, Pinks, and Pansies, were numerously exhibited. The former consisted of the same varieties as shown at Kensington on the previous Wednesday, and it would be useless repetition to record the names of the best. For fifty, Messrs. Paul & Son and Mr. Turner had first prizes, Mr. Cant was second, Mr. Fraser third; for twenty-five, Mr. Ingle first, Mr. Exell second; Mr. Wright, gardener to Mrs. Ramsden, third; for twenty-four, Messrs. Paul & Son first, Mr. Turner second, Mr. Cant third. Of Pinks several very fine stands were shown by Mr. Turner, Mr. Hooper of Bath, and Mr. Hall. Car-

nations and Picotees were also shown in fine condition by Mr. Turner; cut Pelargoniums by the same; Pansies by Messrs. Downie & Laird, and Hooper; and Sweet Williams by Mr. Hally, Blackheath.

NEW PLANTS.—Many of those exhibited have already been frequently noticed in these pages, and it is, therefore, unnecessary to repeat their names. The beautiful white-flowered *Lapageria alba*, however, which came from Messrs. Veitch, and *Lilium auratum* cannot be allowed to pass unnoticed. Mr. Williams, of Holloway, was awarded first-class certificates for *Beaucarnea* sp., for a *Hemerocallis* with distinctly white-striped leaves, and for a *Yucca* having thread-like appendages at the margin of the leaves. A second-class certificate was awarded to the same exhibitor for a variety of *Mimulus cupreus* with the leaves much variegated with white. Mr. Bull had a first-class certificate for the magnificent and scarce new *Araucaria Rulei*, which was shown along with one of its long cones; also, for *Canna nigricans* with dark red leaves; for *Salpiclæna volubilis*, a Fern of twining growth; and for *Geonoma Ghiesbrechtii*, noticed last week. Second-class certificates were given to Mr. Bull for *Pteris albo-lineata angusta*, with narrow fronds having the central portion white; for *Peperomia arifolia* with prettily variegated deep green and white leaves; and for *Pandanus Blumei*.

Messrs. F. & A. Smith again exhibited their new *Lobelias*, of which compacta was the best for dwarf edgings, having at the same time large flowers; and *Gordoniana superba*, azure blue with a white eye was a very fine kind of taller growth.

Dendrochilum filiforme, an Orchid with long racemes of small greenish yellow flowers more curious than beautiful, came from Mr. Lawrence, gardener to the Bishop of Winchester, Farnham Castle; and a brilliant variety of *Disa grandiflora*, called *superba*, from Mr. Watson, gardener to C. Leach, Esq., Clapham Park.

Messrs. Low, of Clapton, had first-class certificates for two very fine new Heaths, one of which was called *Lindleyana*, the other *venosa*; and a similar award was made to Messrs. A. Henderson for *Gardenia florida variegata*, the leaves much variegated with yellow; also for a variegated form of *Rhyncospermum jasminoides*. Rose Dr. Lindley from Mr. W. Paul, a shaded dark crimson and very fine, had a first-class certificate. Amy Hogg, a beautiful rosy purple approaching magenta, and others of the late Mr. Beaton's Geraniums already noticed at page 4, came from the same gentleman. Scarlet *Pelargonium The Clipper* and *Calceolaria Charmer* from Mr. Bull; *Verbena Velvet Cushion* from Messrs. E. G. Henderson, and *Clematis lanuginosa* varieties from Mr. Townsend, of which an account was given at the same page, were again exhibited. Scarlet *Verbena Earl of Aylesford* from Mr. Perkins of Coventry, with a large truss and flowers, had a first-class certificate. Messrs. E. G. Henderson had a like award for *Fuchsia Lucrezia Borgia* with enormous flowers, the sepals reflexed and fine crimson scarlet, the corolla violet and scarlet mixed; Mr. Holland for *Petunia striata perfecta*, a charming rose-and-white-striped variety; and Messrs. Ivory for *Polystichum aculeatum acrocladon*. Beauty of Herts *Calceolaria* from Mr. Watson, St. Albans, a free-flowering orange and brown sort, appeared likely to be useful for bedding purposes.

FRUIT.

The show of Fruit was excellent, but more limited in extent than one would have expected at this season. Good collections were shown by Mr. Henderson, of Trentham; Mr. Bannerman, gardener to Lord Bagot at Fugeley; and Mr. Lynn, Hedsor, who received prizes in the order in which they are named. Mr. Henderson's, which was far the best, consisted of Queen, Envile, and Smooth-leaved Cayenne Pines; three Melons; Chaptal, Muscat, and Black Hamburgh Grapes; Peaches, Nectarines, Cherries, Figs, and Strawberries.

PINES were not numerous. Mr. Bailey, Shardeloes, had two very fine Providences, and the same number of Envilles; Mr. Young, gardener to C. Bailey, Esq., Aberaman, a Providence of 9 lbs. 10 ozs., and Queens of 5 lbs. 4 ozs. and 4 lbs. 4 ozs.; and Mr. A. Henderson an Enville of 7 lbs. The largest Providence, however, was one from Mr. Bailey, weighing 12 $\frac{1}{2}$ lbs.; another from Mr. Hannan, gardener to

R. T. Crawshay, Esq., Cyfarthfa Castle, and from a sucker only twenty-one months old, was 7 $\frac{1}{2}$ lbs. A Prickly Cayenne from Mr. Brown, gardener to Sir C. Knightley, Bart., was 5 lbs.; and of Queens excellent fruit were shown by Mr. Cawkell, Mr. Chitty, Mr. Perkins, and Mr. Godfrey. The prizes awarded were:—For collections, Mr. Bailey first, Mr. Young second, Mr. A. Henderson third; for Providence, Mr. Bailey first, Mr. Hannan second; for Queens, Mr. Cawkell first, Mr. Chitty, Mr. Perkins, and Mr. Godfrey second; for any other variety, Mr. Brown first, Mr. A. Henderson second, Mr. Budd and Mr. Gardiner third.

GRAPES.—In three dishes Mr. Meredith was first with Trentham Black, Victoria Hamburgh, and Black Hamburgh, very fine; Mr. M. Henderson, Cole Orton Hall, was second with excellent Black Hamburghs and Muscats; and Mr. Embrey third with Canon Hall, Muscat of Alexandria, and Black Hamburgh; a similar award being made to Mr. Peachey for Black Hamburgh, Golden Hamburgh, and Grizzly Frontignan. The next class, for baskets of any kind, was a somewhat unfortunate one, as it involved the comparison of such dissimilar Grapes as Black Hamburghs and Muscats. The latter, shown by Mr. Turner with large berries and in good condition as regards ripeness, carried off the first prize; Black Hamburghs from Mr. Meredith, black as sloes and very fine, taking the second; and the same kind from Mr. M. Henderson had a similar award. Black Hamburghs were almost without exception fine. Mr. Sawkins, gardener to G. Brassey, Esq., Brainfield, was first, Mr. Meredith second; the former being, we understand, the heavier bunches, whilst those from Mr. Meredith were the best coloured. Opinions were much divided as to the respective claim of these two exhibitions to hold the first position. Third prizes were awarded to Messrs. Hyde, M. Henderson, and A. Henderson. Of Black Prince, of course, there was no exhibition to compare with Mr. Hill's magnificent bunches, of which special mention was made last week; an error, however, crept in as regards the weight of the largest three, which should have been 13 lbs. 1 oz., or 9 ozs. less than formerly stated. They were the produce of a Black Prince grafted, we believe, on a Mill Hill Hamburgh. Mr. Pottle was second, Mr. Goldsmith third. In Muscats Mr. Turner was first with excellent bunches, Mr. Embrey and Mr. Sage second, and Mr. M. Henderson third. In the Any variety Class, Buckland Sweetwater, shown by Mr. Hill, was first, the three bunches weighing 6 lbs. 3 ozs., and a second lot was 5 lbs. These were much admired. Golden Hamburgh, very fine, from Mr. C. Smith, Norwood, was second; and the same kind was also shown very well by Mr. Hyde. Duchess of Buccleuch from Mr. W. Thomson, of Dalkeith, attracted much attention; the three bunches were from a pot Vine, and weighed 3 $\frac{1}{2}$ lbs. The other varieties exhibited were Grizzly Frontignan, Trebbiano, and Foster's Seedling, many of them unripe.

MELONS.—Golden Perfection, Bromham Hall, Beechwood, Orion, and Hybrid Cashmere were the chief Green-fleshed kinds, and Scarlet Gem the best of the Scarlet-fleshed classes. Mr. Gadd was first in both classes, Mr. Meredith and Mr. A. Henderson taking second prizes.

PEACHES AND NECTARINES comprised fine fruit of Grosse Mignonne, Violette Hâtive, Early Newington, Royal Charlotte, and Noblesse Peaches, and Downton and Elrige Nectarines. First prizes were awarded to Messrs. Rawbone, Sawkins, and Ford; second prizes to Messrs. Hill, Holder, and Miller.

CHERRIES.—Black Tartarian from Mr. Turner, very large and fine, took the first prize in the Black Class; the same kind from Mr. Beck, gardener to Lord Broughton, being second. May Duke was shown by Mr. Meredith, Knight's Early Black by Messrs. Lane. Mr. Enstone and Mr. Turner were first and second in the White Class, both with Elton.

STRAWBERRIES.—The kinds exhibited chiefly consisted of Admiral Dundas, Oscar, Sir C. Napier, Sir Harry, Empress Eugénie, and British Queen, all of which were fine. Mr. Turner had Sir Joseph Paxton, which has already been noticed in these columns. It is large and of handsome form, less irregular in outline than most large kinds, in colour dark red, and it has a slight Hautbois flavour. It has, moreover, the merit of ripening at the same time as Keens' Seedling. Mr. Bailey had the first prize, the second going to Mr. Lydiard.

MISCELLANEOUS.—Some good Figs, chiefly Brown Turkey, were exhibited by Mr. A. Henderson, Mr. Brown, and Mr. Pottle; Raspberries by Mr. Young, Strawberries in pots by Mr. Turner, Vines in pots bearing fine bunches by Messrs. Lane and Standish, and orchard-house trees by the former and Mr. Fraser, Lea Bridge. The Cocoa-nut from Syon was again exhibited by Mr. Fairbairn, and a cluster of *Musa Cavendishii* by Mr. Carr, gardener to J. Hinds, Esq., Byfleet, whose success in cultivating this Banana was specially alluded to in No. 144.

BIRMINGHAM ROSE SHOW.—JULY 7 AND 8.

THE third annual Exhibition of Roses was held on the above days in the Town Hall, Birmingham. It so happened that the second Exhibition of the Birmingham Botanic Society fell on the 7th; but whether this made any difference as regards the number of visitors I can by no means state positively. The day was fine but not hot—indeed such a day as is most suitable for a flower show, so that visitors could enjoy both the Rose Show in the Town Hall and the other in the Society's gardens. If the two Shows falling on the same day made no difference in the number of visitors, it certainly did in that of plants; for Roses, however they may be prized as flowers, do not fill a large hall without an intermixture of foliage. This was not wanting, but more plants would have been better. The orchestra was nicely decorated with an intermixture of fine-foliated and flowering plants, which looked exceedingly well, the effect being enhanced by a temporary fountain.

The Roses were very fine, and made a grand display, both in the body of the hall and also in the galleries, the whole being differently arranged from last year, so as to allow more room for the visitors. Altogether the arrangement was very good, both in the disposal of the blooms and plants, and in that of the various gardening implements, &c., exhibited.

Though I believe the Roses were as numerous as last year, or nearly so, I missed several of the larger exhibitors, and some of the smaller ones also. The Show was, however, a very good one, and there can be no question as to its success. The following is a list of the prizes awarded:—

No. 1. Ninety-six varieties, three trusses.—First, Messrs. Paul & Son, Cheshunt. This collection contained some of the very finest blooms, and was exceedingly fresh, although, probably, too fully blown for a two-days show. I noted the names of some of the best, but I do not think it would interest the generality of readers to give them. Mr. J. Keynes, of Salisbury, was second, his collection very closely following that of Messrs. Paul & Son. The flowers were mostly very brilliant in colour, and sustained the character of the grower.

No. 2. Forty-eight varieties, three trusses of each.—First in this class was Mr. B. R. Cant, of Colchester, with a most splendid collection, the blooms being full and generally well formed, besides being very brilliant, although placed within the shade of the front gallery. Second in this class came Messrs. Paul & Sons, and third Mr. Keynes, both with very good collections.

No. 3. Twenty-four varieties, three trusses of each.—First, Mr. Cant; second, Mr. Keynes; third, Mr. Batley, of Rugby; fourth, Mr. Davies, of Newbury.

No. 4. Twenty-four varieties, single trusses.—First, Mr. Treen, Rugby; second, Mr. Batley; third, Mr. Vertigans, of Edgbaston.

No. 5. Twelve varieties, three trusses.—First, Mr. Treen; second, Mr. Batley; third, Mr. Vertigans.

No. 6 (Amateurs). Forty-eight varieties, single trusses.—First, Mr. S. Evans, Arbury; second, Mr. J. Perry, Castle Bromwich. No. 7. Twenty-four varieties, single trusses. First, Mr. E. Stuart, Leicester; second, Mr. Evans; equal third, Mr. Sage, Atherstone, and Mr. Perry. No. 8. Eighteen varieties, single trusses. First, Mr. S. Evans; second, Mr. Brown, Elmden Hall; third, Mr. Hunt; fourth, Mr. Garnet, Moor Hall. No. 9. Twelve varieties, single trusses. First, Mr. Sage; second, Mr. Stuart; third, Mr. C. E. West, Sutherland. No. 10. Twenty-four varieties, single trusses. First, Mr. W. Brown; second, Mr. Perry; equal third, Mr. Garnet and Mr. Smythe, Solihull. No. 11. Twelve varieties, single trusses. First, Mr. W. Brown; second, Mr. Wright, Perry Bar; third, Mr. Smythe; fourth, Mr. J. Perry.

No. 12. Six varieties, single trusses.—In this class the exhibitors are limited to such as grow their Roses within three miles of what is considered the centre of smoky Birmingham. Last year there was not one entry, but this season there were several, and the trusses exhibited were no discredit to the growers. The first prize was awarded to Mr. H. Lowe, Edgbaston; the second to Mr. E. Sansome; the third to Mr. Wragge, Edgbaston; and the fourth to Mr. E. Sturge.

In No. 13, New Roses of 1862, 1863, or 1864, twenty-four blooms, Mr. J. Keynes was first. His collection contained splendid blooms of John Hopper and Baron Rothschild. The second prize went to Mr. B. Cant for a very nice collection. The third to Messrs. Paul & Son, whose collection contained very fine blooms of Paul Delameilleray, Jean Goujon, Madame Soupert, and Professor Koch. The fourth prize was awarded to Mr. Batley, who had Clement Marot, very good.

In No. 14, the best New Rose of 1862, 1863, and 1864, Mr. Keynes was first with Madame Charles Wood, and second with Charles Lefebvre; Mr. Cant second with John Hopper; Messrs. Paul & Sons fourth with Lord Clyde and Maréchal Vaillant.

No. 15. Best Design, Basket, or Vase of Roses and Rose Foliage.—First, Mr. Vertigans; second, Mr. Evans, Arbury; third, Mr. J. Cole, Birchfield. No. 16, Best Design for Dinner Table Decoration, Flowers to be Roses with other Foliage.—First, Mr. Vertigans; second, Mr. Brewer, Islington, Birmingham; third, Mr. J. Cole. No. 17, Best Bouquet of Roses and Rose Foliage.—First, Mr. Vertigans; second, Mr. Cole; third, Mr. Treen; fourth, Mrs. Sandford, Chepstow.

The above are all the prizes; but there were contributions in the way of plants and flowers, particularly a stand of Verbenas from Mr. J. C. Perry. There were also stands of Roses which were not for competition; one row of boxes from Mr. J. Cranston, containing several hundred blooms, and most of them very fine.—F. CHITTY.

NEW FRUITS.

THIS morning I have had the pleasure of sending you another small case containing two varieties of Cherries and six of Currants. The Cherry No. 64 is Montmorency à longue queue (cultivated among us under the name of Cerise Orange*), and the other is De Jonghe's Transparent. The latter was raised from seed in 1844, and produced fruit for the first time in 1852 or 1853. The tree is of very moderate growth and great fertility, a point which one feels the disadvantage of when strong shoots are required to supply buds for budding. Since 1854 I have tried it in every way, and I have found in the last experiments that the variety succeeds best grafted as a half standard or full standard on the Red Gean. It is less at home on the Black Gean, and much more still on the Mahaleb. Planted *en cordon oblique* against a wall or espalier, leaving the stem to develop itself at leisure, but taking care to pinch the laterals, there will be, in the second year, all along the stem, fruit double the size of the specimens I send in the case. As you see it the fruit is of very good quality.

When the tree first bore fruit, after having examined and tasted it, I gave it the name of "Transparent," and, to distinguish it from other varieties bearing this name, I added my own as raiser of the variety. This denomination is in conformity with the system of Baron Truchsess, now generally admitted in the science of pomology. It is also under this name that I have furnished many plants of it to Mr. Thomas Rivers, and you have described it† from fruit received from that gentleman, without at all indicating its origin.—J. DE JONGHE, Brussels, July 6th.

[DE JONGHE'S TRANSPARENT CHERRY.—We cannot speak too highly of this delicious Cherry, which in size equals the May Duke; the skin is thin and transparent, showing the texture of the flesh through it, and is of a pale red colour. It is sweet and richly flavoured.

RED CURRENTS.—No. 5 is an abundant bearer, and pro-

* This is a very distinct Cherry from our Kentish, with which it is made synonymous in the Horticultural Society's Catalogue.

+ JOURNAL OF HORTICULTURE, Vol. IV., page 41.

duces good-sized bunches, bearing from fourteen to eighteen berries on each. The colour is of a fine brilliant red, and the flavour much less acid than that of the Red Dutch Currant grown in this country. No. 6. In this we do not distinguish anything different from the Red Dutch, and it is inferior to the Long-bunched Red. No. 7 produces shorter bunches than either of the above, and is possessed of a mild acidity. It is not, however, an improvement on existing varieties, except in that respect, for it is much less acid than even Knight's Sweet Red. No. 8 is too much like Red Dutch in every respect.

WHITE CURRANTS.—No. 35 appears to be a very late variety, comparing it with the fruit of the following, which is dead ripe while the former is quite hard and green. No. 38 appears to be a great bearer, but in the bunches and berries it is not superior to existing varieties.]

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE Anniversary Meeting of this excellent Society was held on Friday, July the 8th. The Right Hon. Charles Lawson, the Lord Provost of Edinburgh, presided, supported by R. Wrench, Esq., J. A. Henderson, Esq., J. Lee, Esq., J. Veitch, Esq., Messrs. Addiscott, Barnes, J. Bolton, J. Bruce, J. Cutbush, &c.

THE LORD PROVOST said—I beg now to propose the health of "Her Most Gracious Majesty the Queen." Although I have never had the honour to propose this toast in London, I feel assured that it will be greeted with the same hearty loyal reception which it never fails to call forth in the north, and everywhere throughout the British dominions. We are a loyal people, and will always respect and pay homage to our Sovereign. But Queen Victoria possesses, and deserves to possess, more than mere homage and respect. She has gained the love and confidence of her people; and well she may, for her whole life has been adorned by the unaffected display of virtues, never more brilliant than when they grace the exalted and illustrious position which Her Majesty occupies. The Queen has earned a great and a good name in history, and I trust she may be long spared to us.

THE LORD PROVOST said—Our next toast is to "The health of their Royal Highnesses the Prince and Princess of Wales, and the other members of the Royal Family." From what little I have had the honour of seeing of the Royal Family, and from a great deal I have heard, there are few families owe more to the care and anxiety which their parents have bestowed upon their early training, and few parents have ever had more teachable, well-disposed, and noble-minded children. I believe there is but one feeling in the country regarding the Royal Family, and that is, that the Prince of Wales, his fair Princess, and every individual member of that illustrious circle, are conducting themselves with a propriety and a grace which reflects the highest honour upon themselves, and, I may almost say, if possible adds to the brilliancy of that lustre which their Royal parent has shed over the British Court [loud cheers].

THE LORD PROVOST—I have now the honour to propose the health of those services which have for centuries guarded the freedom and the honour of our flag. If ever there was a time when we should desire to see our Navy and our Army in good discipline and ready for work, in my opinion we should desire to see that now. For some time past those clouds which have been gathering round the political horizon of Europe have been creeping on towards us, and darkening as they crept. Whatever may be the result of the excited state of feeling abroad, it is impossible to say; but, come what may, our soldiers and sailors are as brave and daring as they ever were; and if circumstances compel us to assert the dignity and authority of the British flag, woe betide the foe that may have the temerity to question our doings. I am glad to know that our Volunteers are still keeping up their numbers, and are still maintaining their efficiency in drill and rifle exercise. They may yet be called upon to guard our shores, and I know they will do it well. I beg to propose the health of those services [tremendous cheering].

THE LORD PROVOST—I have now the honour to propose what on the present occasion must be regarded as the most

important toast of the evening: "Success and Prosperity to the Gardeners' Royal Benevolent Institution." It is, perhaps, one of the finest features of this country, that private generosity and the kind feeling of the prosperous perform those obligations which the fortunate owe to the unfortunate, which in some countries are discharged by the Government, and in others left undischarged altogether. Now, in Great Britain the number of benevolent institutions is most amazing, and they form in my humble opinion no unworthy monument in honour of the public sense of duty which beats nowhere stronger than in a British heart. Amid all the benevolent institutions in the country, I do think it is but fair that one should be devoted to gardeners, for I do not know that a more deserving, a more hardworking, or a more useful class of men exist than they; and more than this, their profession is peculiarly calculated to excite our sympathy for them in the days of their adversity. We have undoubted testimony that the gardener's is the most ancient profession of all; and it has often occurred to me that the employment of gardening is the most innocent, and productive of the most happiness and pleasure. In a perfect state of things one can almost imagine all kinds of professions being done away; indeed, things would be anything but perfect if certain learned professions continued to exist; but the tending to all the beauties of the floral creation and the caring for the rich variety of fruits with which Providence has so bountifully endowed this earth, honestly appears to me to be compatible with an existence as perfect as we can imagine it to be. In that perfect state of things gardening would be a pastime, and gardeners, probably, something like angels; but at present they are only hard-working men, and they have to go through much toil to support wives and children, and unhappily it not unfrequently happens, that in old age the poor man who has been the means of administering so much comfort to his fellow creatures, who has, no doubt, again and again adorned our tables with flowers, and served us with the choicest fruits; who, in fact, has done his little to help in restoring the earth to its pristine beauty from which it has so lamentably fallen—I say it often happens that this quiet, hardworking administerer to our joy and comfort, is overtaken by the hand of misfortune, his age embittered by sickness, and nothing to look to but the kindness of those who are unwilling to see an honest, good man go without a helping hand when he needs one. Happily this Institution exists, and we now celebrate its 21st anniversary. I am sure the history of the Institution is well known to most of those friends I see around me; but as some strangers have honoured us with their company, I think I may be forgiven if I say a few words as to its progress:—During the early years of the Institution little or no good was effected, but in 1843 some beneficial changes in the management were introduced; it received the Royal patronage in 1851, and has gradually progressed in usefulness, affording annuities to deserving applicants above sixty years of age; of £16 and £12 to men and widows respectively; giving always a preference to subscribers, which has been found to encourage habits of prudence and economy through life. At this moment there are fifty-five persons preserved from the evils of poverty and sickness by this Institution. It is entirely supported by annual subscriptions, collection at the anniversary dinner, and the dividends on £5500 funded stock. My friends Mr. Wrench and Mr. Cutler kindly consent to continue their services as Treasurer and Secretary; and of the twenty-four members forming the Committee of Management, one-third of that number are always practical gardeners. Now, I hope no one will esteem it a fault on my part when I say, if all the well-to-do gardeners were to come honourably forward and subscribe their mite towards an institution eminently their own, they would only be doing by their less fortunate brethren what reason, ordinary kindness, and duty should prompt them to do. I hope that all our landed gentry will consent to become subscribers to this Society—every one should, indeed, who enjoys the luxury of flowers, fruit, and vegetables. The ladies, especially, ought to think of the poor gardeners, whose hands have reared the flowers which give them so much pleasure, and enhance so beautifully their charms; but with the gardeners it is a positive obligation, and I trust that ere long such will be the success of the Gardener's Royal Benevolent Institution, that not a single gardener or gardener's widow in the

country, who may be in true misfortune, may have to ask twice, or ask in vain, for its sheltering protection.

The LORD PROVOST said—The next toast which I have the pleasure to propose, is one to which I am not sure whether I should allude in its official or private capacity. I beg leave to propose “The Health of the excellent Treasurer of this Institution, an esteemed friend of my own, Mr. Wrench.” In the particular branch of commerce in which I and many around me have been engaged, it is well known that Mr. Wrench’s name is a kind of household word; and I am sure I only say with truth, that both his own name, and the name of his father before him, are held in an estimation which reflects the very highest credit upon the firm and upon every individual member of the family which raised, by their talent, industry, and high sense of honour, that firm so high in public opinion. It is most creditable to Mr. Wrench to find him, while even yet immersed in the anxieties of business, holding a responsible office in this benevolent Institution; and I well know that he holds it with great credit to himself, and that he has spared no effort to bring his services to bear successfully on the prosperity of the Institution. I know that for the success of the Gardeners’ Benevolent Institution we must also look to others than the Treasurer; but I always think it good to have a lucky Treasurer, and, as I cannot but regard Mr. Wrench as a lucky man this evening, surrounded as he is by so many munificent benefactors to the Institution, I congratulate the Institution in possessing so fortunate an omen of its future prosperity.

The Lord Provost’s health was next drunk most enthusiastically, when in returning thanks he said:—I am quite at a loss how to thank you adequately for the very kind manner in which my health has been proposed, and the more than kind manner in which it has been received. I assure you when I was asked to preside at the dinner I felt myself much complimented, for I knew how many more distinguished persons and more deserving might have been chosen for such an honour; still, from a feeling of pride I suppose, I could not refuse the compliment, and I have now had the intense satisfaction of presiding at an English dinner in your own English metropolis. Permit me before I sit down to say a word in praise of what I consider a noble feature in the English character—it is free from all prejudice, and in this forms a brilliant example to your neighbouring fellow countrymen north of the Tweed and across the Channel. In this great city you invite all and sundry—Scotch, Irish, foreign—no matter where they come from they are all welcome, and welcome to do as they choose. I call this a grand national characteristic, and to it London is in no small measure indebted for the proud position she holds among the nations of the world, even England herself, indeed, for her greatness; and, to compare great things with small, I am indebted for appearing here this evening. I shall long remember the agreeable entertainment we have just had, and again thank you most warmly for your kindness to me.

The health of the Ladies, who mustered strongly in the gallery, was next given.

The musical arrangements were admirably carried out by Miss Poole, Mr. W. H. Cummings, Mr. Montem Smith, and Mr. Lewis Thomas. Mr. W. H. Thomas acted efficiently at the grand pianoforte; and our old friend Harker as usual made an able toastmaster. The dinner was of a most *récherché* character, and gave great satisfaction.

SKELETONISING LEAVES.

SOAK the leaves in soft water until the green parts are perfectly decomposed. Pour off this water and fill the basin with fresh water. The basin must be large enough to hold the hand comfortably. Put the hand into the basin, and, holding the leaf under the water, gently manipulate it between the fingers and thumb (using only the tips of the fingers), until every particle of green comes away. If it does not do so easily, the leaf requires more soaking. Fingers have a far more delicate touch than any brush. A piece of white blotting paper raises the leaf out of the water better than writing paper. Pass the leaf once or twice through a solution of chloride of lime, half a teacupful of the powder

to a pint of water. Dry them gradually between folds of blotting paper not too much pressed, and remove them either to mount or to preserve in any manner you please before they are quite dry.

MUSCAT GRAPES.

As the interesting and instructive remarks on “Choice of Grapes” by Mr. Pearson (page 454), were offered partly for the purpose of eliciting the opinion of others, I am induced to offer a few remarks on the choice of Muscat Grapes.

When Mr. Pearson says that it signifies very little which variety of Muscat, excepting the Canon Hall, is planted, I have no doubt he speaks from his own experience; and there is no doubt that under skilful management and favourable circumstances he is, to a certain extent, correct. There are, however, varieties of the Muscat which are not attended, under ordinary circumstances, with that precariousness in setting which belongs to what is generally known as the old Muscat of Alexandria, and which results in the many samples of that Grape which are to be met with having irregularly set or stoned berries, and which greatly disfigure the bunches. First-class management can and does overcome this objectionable tendency in the old Muscat; but there are many instances in the present day in which Muscats are planted and fruited at the hot end of comparatively cool vineeries, and under other circumstances not favourable to complete success in setting and maturing the berries.

Under such circumstances I think the selection of varieties of the very greatest moment, because I have found that there are one or two varieties of Muscat, every berry of which sets and ripens in a temperature where the same success does not attend the old Muscat, and which are in size of berry and flavour, more particularly in the former point, more than equal to any of the Muscat section.

The varieties I allude to are the Tynningham and Bowood Muscats, both of which set as freely, and can be thinned as freely, as the Black Hamburg in a temperature lower than is necessary to secure the same result with the old Muscat. Moreover, both these varieties, with me at least, make finer berries than the old Muscat, while they ripen sooner, and are easier brought to that amber pitch characteristic of first-class Muscats. They can be shut up for forcing the first week of February, and placed ripe on the table in the last week of June.

I think these are points well worthy of the attention of those who grow Muscats in a mixed collection, or who have not the command of a high temperature. The two sorts I recommend I am certain will give more satisfaction in setting and ripening in a moderate temperature than the old Muscat.

What Mr. Pearson says about their general appearance when ripe and placed on the table may be, to a certain extent, correct. But I have for some time grown the three sorts to which I refer, and I would never think of planting the old Muscat while I could obtain the other two.

Some time ago an effort was made to prove the Tynningham and Bowood varieties identical, but some who entertained that opinion think differently now; and they are, with me, more distinct in wood, foliage, and general character, than are some of the Black Hamburg varieties of Grapes, which are, nevertheless, varieties.—D. T.

MR. TOWNSEND’S SEEDLING CLEMATISES.

My attention has been directed to the concluding paragraph of the proceedings of the Floral Committee of the Royal Horticultural Society of June 29th, as reported in the last Number of your Journal. The insinuation contained in this paragraph is calculated to seriously damage my character as a florist, and, therefore, I beg to be allowed to occupy a small space to furnish the gentlemen composing the Floral Committee (and of whose names I am entirely ignorant), with some information respecting the seedling Clematises submitted by me for their judgment.

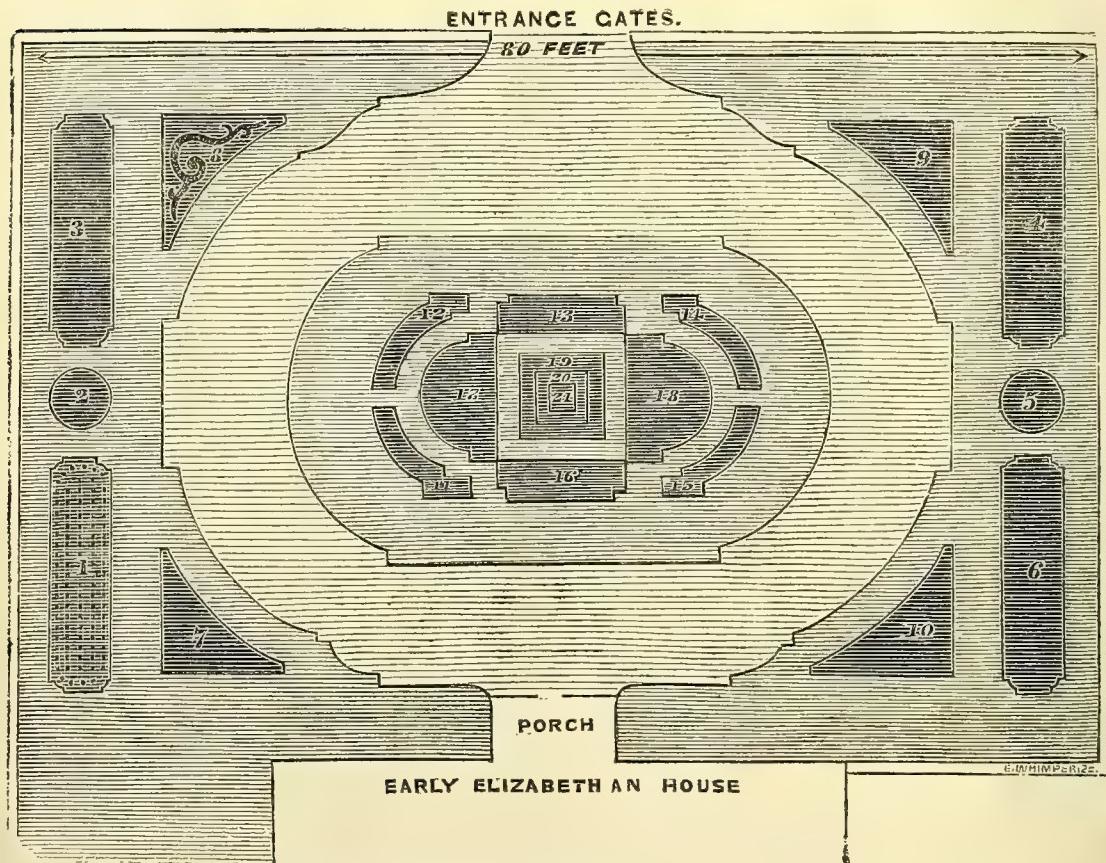

The seed from which these Clematises were raised was hybridised and gathered by me. I came to St. Mary’s Nursery, Hornsey, at Christmas, 1862, immediately after which the seed was sown. The plants exhibited were the

produce of that seed, and have never been out of my possession. Some of them bloomed last year, and one of the plants exhibited is a plant of this year's growth, and bloomed for the first time this summer. I still have of this year's growth more than twenty plants from the same seed, none of which have yet bloomed, but are now showing bloom, which I shall be happy to show to any person who may favour me with a call, and answer any questions concerning them.

None of these Clematises have ever been shown till they were exhibited at the Alexandra Park Flower Show, June 22nd; they were there awarded first-class certificates of merit. They were then submitted to the judgment of the gentlemen composing the Floral Committee of the Royal Horticultural Society, June 29th. Since then they have

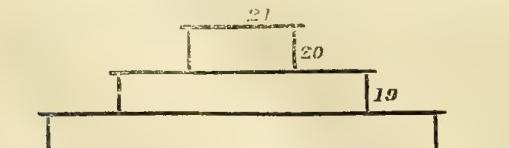

been exhibited at the Royal Botanic Society's Flower Show, Regent's Park, when they were also awarded certificates of merit. These were the only times the plants have ever been exhibited. I feel assured the gentlemen of the Floral Committee would not willingly injure my reputation as a florist by unjustly doubting my integrity; and as they appear to have withheld their commendation of these Clematises from some doubt as to their origin, I trust this explanation will be satisfactory to them, and that they will do me the justice to award me any certificates they may think these plants merit; or should they desire it, I am willing again to submit them for their opinion at any future meeting of the Committee.—THOMAS TOWNSEND.

FLOWER GARDEN PLAN.

- | | | | |
|---|--|---|---|
| 1. Centre Golden Chain Geranium, surrounded with Bijou, and edged with Lobelia. | 5. Christine Geranium, Nierembergia, Variegated Alyssum. | 12, 15. Lady Plymouth, dotted with Lobelia. | 19. Tropaeolum elegans, edged with Lobelia, and Lady Plymouth Geranium planted alternately. |
| 2. Henri de _____, Nierembergia, Variegated Arabis. | 6. Cerise Unique Geranium, Lady Plymouth, Lobelia. | 13, 16. Cloth of Gold Geranium, edged on outside only with Perilla. | 20. Christine Geranium, edged with Nierembergia. |
| 3. Boule de Neige, Spitfire, Lobelia. | (2, 3, 4, 5, 6, planted as No. 1.) | 17, 18. Cerise Unique Geranium; Calceolaria Aureoflora, edged on outside only with Perilla nankinensis. | 21. Perilla nankinensis, edged with Variegated Alyssum. |
| 4. Bijou Geranium, Golden Chain, Lobelia. | 7, 8, 9, 10. Cera-tium with pattern as shown in Perilla. | | |
| | 11, 14. Lady Plymouth Geranium, dotted with Brilliant. | | |

THE garden is surrounded by a wall as shown. The gravel path is wide, as it is used as a drive up to the house. The

centre beds 19, 20, and 21 are raised one above the other,

as in the accompanying woodcut. The sides are of slate painted like stone. No. 6 bed would have been planted as No. 3, simply reversing the position of Boule de Neige and Spitfire, but I had not a sufficiency of these Geraniums.—A SUFFOLK SUBSCRIBER.

[We think your garden will look very well as proposed if you give it the necessary pruning and regulating, especially as respects the Perilla outside of the beds. We think, however, that you have too much Perilla; and a line all round the figures 13, 16, 17, 18 will give a sombre appearance, especially being next the grass. Charlwoodii and Purple King Verbena would suit better. The Perilla will

want so much regulating outside Cloth of Gold and *Aurea floribunda Calceolaria*, that if you must use Perilla we would put it in the middle—thus: 13, 16, Perilla, Cloth of Gold; 17, 18, Cerise Unique Geranium (strong plants), Perilla, *Aurea floribunda*. In 21 we would put Scarlet Geranium instead of the Perilla; 19 and 20 as stated. Then as you cross 11, 14, and 12, 15, which will do well, and all the better from the above proposed alteration, we would take that crossing as the guide for the other planting; and we would thus make pairs of 1 and 4, 3 and 6, 7 and 9, 8 and 10: the last two might have *Amaranthus melancholicus* instead of Perilla. By your proposed mode all your edgings of the corner beds would be Perilla, all the outside ones Lobelia. By the proposed plan the inner would be yellow, the outer blue. Even blue is tame against grass. Give rich top-dressing to the Verbenas, and rotten leaf mould to the Calceolarias, firming the soil well.]

THE WANT OF VARIETY AMONG TREES AND SHRUBS IN PLEASURE GROUNDS

AND ORNAMENTAL PLANTATIONS.

WHEN we consider the great taste for ornamental gardening at the present time, the numerous fine hardy trees and shrubs which are capable of enduring our climate, and the moderate price at which they can be obtained, it is rather strange that the shrubberies and ornamental plantations in very many places of note are still mostly composed of the oldest and commonest kinds of trees and shrubs; which, with few exceptions, have occupied similar places in our gardens since the days of Philip Miller and Abercrombie. The great lack, however, of variety at the present time in most pleasure grounds and ornamental plantations is perhaps more owing to the generality of planters not knowing the different species and varieties of hardy trees and shrubs that we now possess, and the kinds which are best suited for the purpose.

One of the principal reasons for planting different kinds of trees and shrubs in a plantation or pleasure ground is to create as much variety as possible in the scenery, by the display of the natural character and outline of the heads of the larger trees at a distance, and the smaller trees and shrubs near at hand; for the object of variety is not like that of mixture, to puzzle and confound the spectator, but to charm and delight by leading the eye a sort of wanton chase, as Uvedale Price has expressed it, "from one beauty to another; alike, but yet different;—presenting in the detail novelty at every movement, and all parts conspiring to form a beautiful and harmonious whole." Therefore, when trees and shrubs are planted for ornamental purposes in or around the pleasure ground, or near the mansion, they should in all cases present as much variety as possible, so as to make these spots attractive and interesting, more especially as the trees and shrubs planted in such places are for the most part permanent and confined to belts or clumps placed in prominent parts, for the purpose of forming screens, or planted singly for varying the general aspect of the place, or separating one part of the grounds from another.

Mr. Loudon says, "The first step towards a knowledge and taste for variety is to be able to distinguish variety from mixture," and "that a knowledge of what variety is would lead to an effectual desire to possess it." Now, if, as Mr. Loudon so justly observes, such a desire were applied to the planting of the various hardy trees and shrubs which we now possess, what an amazing increase it would produce in the arborescent riches of country seats as compared with what they now are; besides, it would lead to the employment of ten times the number of species and varieties of hardy trees and shrubs that is at present grown, and so displace the present meagre, monotonous, thicket-like mixtures that ladies and gentlemen are now content with in most parts of the country. Again, if all the species and varieties of trees and shrubs which bear the open air in this country, and which have any pretence to ornament or distinction, were planted at gentlemen's country seats, what an interest would such places then excite as compared to what they do at present; and all that seems wanting to produce this interest, enjoyment, and commerce is a more

general knowledge of all the hardy trees and shrubs, their habits, and the sizes which they attain, on the part of those who are entrusted with their selection and planting, and a little more taste, ambition, and a desire to have them properly named by their employers; for when a large variety of trees and shrubs are properly arranged and named they form a fine contrast, and add greatly to the interest of the place.

The number of hardy trees and shrubs which we now possess is large and admits of very great choice in the formation of ornamental plantations, where variety always adds both to the attraction and beauty of the place; for every tree and shrub has its peculiar character. The Lombardy Poplar, for instance, has unity of design and an unsocial habit, which forbids the mingling of its branches with those of other trees; while the Weeping Ash disobeys the ordinary law of vegetation, and grows downwards. Every tree and shrub, likewise, has its two characters, both of which are natural to it, the one when it grows up in a mass or among others, and the other when it grows singly, with ample room for the extension and development of all its parts. In the former case the stem or stems are mostly straight, and comparatively free from branches near the ground, while in the other the tree extends its branches amply on all sides, and retains them down to the ground. It is, therefore, obvious that plenty of room and pruning are of the greatest importance in the management of ornamental plantations and shrubberies, and quite as requisite as in timber plantations.

In plantations where large and small kinds are intermixed, and especially flowering ones, the chief object should always be to show the individual character of each species or variety and the beauty of its blossoms, and for these purposes the plants must never be crowded together. Nearly all trees and shrubs are planted as permanent objects, which increase both in size and beauty every year, and when a large assortment of them is introduced and properly arranged in the pleasure ground or ornamental plantation, a succession of changes, not only of foliage and flowers but in the general aspect, takes place nearly all the year round; for a perceptible change is constantly going on in the plants, caused by their perpetual progress, not only to maturity, but to dormancy. Such changes are exhibited by the various tints of the young expanding leaves in the spring and the maturer shades of summer, by the various hues assumed by the dying foliage of deciduous kinds in autumn, and by their leafless spray in winter. Every species of tree and shrub has its peculiar habit of growth, tint of colour, and outline, and, consequently, requires sufficient space for the full development of its characteristics, and if these are not carefully considered at the time of planting an evil is created that frequently is not noticed afterwards until it becomes too late, and the result is either the mutilation or sacrifice of some of the finer specimens, which, if due consideration had been exercised at first, would have been avoided. Nothing can be worse than to see in a pleasure ground two or three nearly full-grown trees of different species and habits with their heads and branches mutilated or interwoven, and destroying the outlines of each other.—GEORGE GORDON, A.L.S.

NEW STRAWBERRIES.

It is a rule with me, from which I seldom depart, to speak only of good Roses and Strawberries, and say nothing of those which are bad or unsuitable to my locality, especially if they have been kindly sent by the raiser. Moreover, an article may be good elsewhere that is not good here.

These are very good; and judging them under unfavourable circumstances, they may be safely recommended.

1. THE ROYAL HAUTBOIS (Rivers), is an immense cropper, and the fruit is very large and delicious. The plant is a hardy hermaphrodite.

2. LUCAS (De Jonghe), derived from La Constante, is excellent, harder, and a better grower. I do not think, as some do, that it is superior to La Constante, but it is excellent, and is a heavy cropper. The fruit is nearly round, and handsome. It is more suitable to different soils and localities. The plant does not burn under a torrid sun, as I have seen La Constante do. It is also a better winterer.

3. BOISSELOT SEEDLING No. 1 (called, I believe, *La Vin-euse*), a latish Strawberry, is excellent, as a plant a heavy cropper, with round fruit of good flavour, with a slight briskness. It is very hardy and quickly established—a point of great moment in this precarious climate. I speak of these three Strawberries after their second year's trial.

4. BIJOU (De Jonghe), is a pretty dwarf-habited plant, slow in growth, but healthy and tolerably hardy. The fruit is of regular and perfect shape, round-coned; but alas! from my only three plants the innumerable birds have pulled off the net, and saved me the trouble of tasting.

5. JOHN POWELL (Ingram), is Queen-leaved and Queen-flavoured. The plants came late last autumn, I could not therefore expect a crop. I have tasted sufficient berries to say it is first-rate. The fruit is irregular, round-coned, and handsome. The flesh is solid to the centre and firm. It is juicy and pine-flavoured. I fancy it will be one of the very best new sorts, and remain in the catalogue. I have taken off all the remaining fruit in order to "make plant," as the plants had a severe winter in their unestablished state. The Frogmore Pines (in huge crop and size here), and John Powell do Mr. Ingram the greatest credit. The former is one of the greatest leaps in the Strawberry line.

6. LORD CLYDE (Dean), is strong as a plant and quickly established. I received it late this spring in the midst of hoar frosts. It is a first-class Strawberry. I saved sufficient fruit from my two plants to speak of it highly. It is of fine flavour, and also the most honey-sweet Strawberry that I ever ate. I think it will be a cropper. The berries are not uniform. They are round, cockscombed, or double-breasted. They are not so firm as John Powell, but I fancy they are equal to it in flavour. These three are in their first year of trial. The last two have well pleased me.

Here, then, are five novelties, a pentateuch of excellence, that stand out in bold relief from an annual inundation of trash.—W. F. RADCLIFFE, Rushton.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE June meeting of this Society was presided over by A. T. Stainton, Esq., F.L.S., in the absence of the President. Amongst the donations to the library received since the last meeting were the publications of the Zoological and Botanical Society of Vienna, the Royal Agricultural Society, the Entomological Society of New South Wales, &c.; also a new work by M. Simon on the Spiders, and an elaborate monograph on the Bos Flies (*Estridæ*), by Herr Brauer of Vienna.

Mr. Morris exhibited some leaves of the Sugar Cane received from the island of Mauritius, where the canes are infested to an alarming degree by a species of Coecus closely resembling the common Vine Coccus, and which was supposed to have been introduced from Belgium or France. The young leaves of the canes both in Mauritius and the island of Réunion are especially infested to a great degree by the insect. Sulphur had been applied to a certain extent, but it was very difficult of application. Carbolic acid had also been strongly recommended to be used as a wash in a diluted form. It was in dry weather especially, when the leaves are succulent, that the pest is the most troublesome.

Mr. F. Smith exhibited, on behalf of Mr. Atkinson of Calcutta, a number of drawings of the Lepidopterous insects of India, executed by native artists with a delicacy of touch and precision of colouring quite marvellous. Many very rare and interesting species were thus represented, especially some singular varieties of the extraordinary *Epicopeia polydora* and *Calinaga Buddha*. He also exhibited a Humble Bee (*Bombus* sp.), captured by his son on Deal sands, which was evidently distinct from any previously-described British species; also, on behalf of Mr. S. Stone, a series of six nests built by a colony of *Vespa germanica* in cubical boxes glazed in front, and exhibiting a variety of most fantastic forms, one resembling a large cup on a pedestal, another the columns of a stalactite cavern, and one was a fair miniature representation of Stonehenge. Professor Westwood suggested that Mr. Stone had induced the Wasps to build their nests in these curious shapes by introducing small pieces of wire in different positions, of which the wasps took advantage as affording support to their combs.

Some notes were also read on the destruction of queen Wasps in the spring of various years, proving how greatly the development of these insects is affected by the varieties of climate. In cold springs scarcely any wasps could be seen, but in dry and warm ones vast numbers were found; thus, in 1841 as many as 586 dozen of queen wasps were caught and destroyed.

Mr. F. Smith objected to this wholesale destruction of Wasps (each queen, of course, representing an entire future colony), considering that Wasps were rather beneficial in the economy of nature than otherwise.

Mr. McLachlan exhibited a Case-bearing caterpillar found on Thyme at Box Hill, differing from any hitherto observed Lepidopterous Case-bearer. The specimen in question was, however, stated by Professor Westwood to be the larva of the Coleopterous genus *Clytara*.

Professor Westwood also exhibited a number of minute four-footed Acari, which had been communicated to him by Mr. Chapman of Glasgow, and which had proved very destructive during the present spring to the buds of the common Black Currant, within which they were found in vast numbers, and of which they destroyed the embryo bloom. He also exhibited and read the description of a new and remarkable Butterfly from Assam and Singapore, forming the type of a new genus, to which he gave the name of *Liphyra Brassolis*; the Butterfly, although belonging to the family Lycaenidae, exhibiting a great resemblance to the robust body *Brassolis* of South America.

Mr. Bates read a communication from Mr. Trimen of Cape Town, giving an account of an interesting instance of mimetic resemblance traced to its object in the instance of a species of Spider which resides on the *Senecio pubigerus*, Linn., and which so exactly resembles the flowers of that species of Ragwort in its colours and markings as to deceive the small species of Butterflies, which it captures and devours when they fly down to settle upon the supposed blossom.

Major Parry exhibited a curious case of monstrosity occurring on an exotic species of Stag Beetle, *Odontolabis Stevensii*, the antennæ of which were divided into three branches.

Mr. Stainton exhibited the curious pupa of a small Moth, *Anchinia verrucella*, which closely resembles that of the Butterflies of the genus *Pieris*, being attached by threads at the tail and girt round the body.

Mr. Tegetmeier made some observations on the economy of Hive Bees, especially with reference to their habit of clearing out and taking possession of old combs, which they have the instinct to fasten with fresh wax at the top, and also on their feeding upon pollen.

Dr. A. Wallace gave an account of the successful rearing and winding-off of the silk of the *Bombyx Cynthia*, which feeds on the *Ailanthus*, at Colchester. Specimens of the silk as carded from the cocoons, spun silk, and woven silk were all shown, together with a skein of ailanthine spun from the cocoon in a continuous thread, which had until quite recently been considered impracticable.

Mr. F. Walker communicated a memoir containing descriptions of new species of Chalcidites, of the genus *Smiera*, brought from the Amazons by Mr. Bates, and now in the British Museum.

WORK FOR THE WEEK.

KITCHEN GARDEN.

PERSEVERE in the all-important operation of stirring the surface of the soil at every favourable opportunity. There is no kind of soil which will not be benefited by this operation, but more particularly for those having a tendency to run together or bind it is indispensably necessary. No one who has not followed out the system perseveringly can truly estimate the great advantages resulting therefrom. It is very proper to apply stimulants in the shape of manure trenched in and incorporated with the staple soil, or in a liquid state during the growing season; but the benefit of such applications is greatly increased by continued, and, as far as possible, deep surface-stirring; for it is the atmospheric agents acting upon and combining with the substances composing the food of plants, which reduce them to a fit state to be taken up through the roots and assimilated.

lated by the plants. *Cabbage*, make another sowing for autumn use. *Carrots*, make a small sowing if they are in request for drawing young, also a few more Onions for the same purpose. The Tripoli Onion answers best. The autumn-sown ones transplanted in the spring will now be attaining their full growth; as soon as this is perceived lay the tops down with the back of a wooden rake for some time previous to pulling. *Celery*, the main crops must now be got out without delay. Let the plants be well supplied with water, and shaded for a few days if necessary. The early crops to be liberally supplied with liquid manure, and the soil about them frequently stirred with a fork; but by no means make any attempt at moulding up until they have nearly attained the desired growth. *Peas*, continue to earth up and stake, the last sowing of these may now be made. The Early Frame is generally recommended, but Knight's Dwarf Marrow will also succeed if the season prove fine. *Potatoes*, the spaces between the rows of early Potatoes should be deeply forked up, and planted with the latest crop of Brussels Sprouts, Kale, Coleworts, and other winter and spring Greens. They will not interfere with the well-doing of the Potatoes. *Scarlet Runners*, earth-up and stake the later-sown, unless they are required dwarf, when the tops must be frequently pinched out; but it is always best to stake them if possible both for neatness and productiveness. *Tomatoes*, keep them well thinned out and constantly nailed. *Turnips*, keep up good successional sowings, of which a large breadth may now be got in. Dry wood ashes or charred refuse sprinkled over them when they are wet is a good preventive against the fly.

FRUIT GARDEN.

Keep the young wood of wall trees constantly nailed in. Spur-in the young wood of Gooseberries and Currants, it increases their productiveness, and also the fineness of the fruit. Care will still be required to keep down the ravages of aphides on wall trees by frequently syringing. Strawberry plantations, that are to stand to bear another crop, to have all the superfluous runners cut away between the rows, and all weeds carefully removed; but on no account let any of the foliage be cut away at this season. Most kinds of fruit now ripe or ripening, will require the protection of nets to preserve them from birds. Peaches and Nectarines should have their final thinning when the stones in the fruit get firm and hard, as all the risk of dropping during the stoning process will then be over. Vines against walls to be nailed to the wall. Pinch out the points of the current year's wood (except the leaders), of Figs when they have made five and six joints.

GREENHOUSE AND CONSERVATORY.

Shading should be used sparingly, except on bright days, for during dull unsettled weather plants require all the light that conservatories, the roofs of which are partially shaded by twiners, afford, and are greatly benefited by an occasional gleam of sunshine. The beauty of most softwooded plants will be considerably prolonged by the use of weak liquid manure, which should be given frequently. Indeed such things as Achimenes, Clerodendrons, &c., may be had in full beauty from June to October through being liberally supplied with manure water; but this must not be given too strong at first. Keep the atmosphere as moist as can be done; but avoid damp on cold nights by leaving sufficient air to cause a gentle circulation, and spare no attention to keep the plants clear of insects. Chinese Primulas, especially the double varieties, if at all backward, should be placed in a cold frame and shaded from the sun, where they will make rapid progress, particularly if the pots stand on a slight bottom heat. A thorough revision of plants belonging to the greenhouse should now take place with the view of affording them a final shift for the season, giving, where necessary, support by judicious tying, and repairing irregularities of growth. The obvious reason for shifting during the summer is, that before the approach of winter the plants may possess a sufficient mass of roots to support them through that trying season.

FLOWER GARDEN.

Go over the beds frequently, and keep the young shoots of Verbenas, &c., nicely regulated and pegged down until the ground is fairly covered, after which the shoots may be allowed to grow more at liberty. On poor dry soils two or

three applications of weak manure water, given at intervals of a few days, and when the ground is moist, will greatly assist in getting the beds covered without loss of time. See that Dahlias, Hollyhocks, &c., are securely staked and properly tied as they advance in growth. Manure water will also be useful to these. Remove dead flowers and seed from Roses, and give the autumn-flowering varieties plenty of manure water, in order to keep them in vigorous health and secure plenty of wood for blooming in the autumn. Budding should be proceeded with in cloudy weather. Mildew is sometimes very troublesome after this season, and no time should be lost in dusting the infested plants with sulphur.

PITS AND FRAMES.

The stock here will now be growing freely, and should be frequently examined individually to see that all is going right, for plants when growing rapidly very speedily suffer through neglect in watering, or from the attacks of insects. Examine young specimens that were potted early in the season, and shift at once such as require more pot room, so as to get the pots moderately well filled with roots before the winter, in which state plants are much more easily carried through the winter than when either over or under-potted. Leschenaultias should be carefully examined for green fly. Chorozemas, Bossizas, &c., must also be frequently examined for red spider and laid upon their sides on a clean mat and thoroughly washed with the syringe, repeating the syringing as often as may be necessary to eradicate the pest. Young specimens of valuable hardwooded plants should be carefully trained, keeping the shoots nicely tied out or pegged down in order to secure close compact specimens. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

HERE our work has been much the same as in previous weeks, with the exception of clearing off our first Cauliflower, and dunging and trenching the ground for Strawberries—to be transferred from pots that were forced under glass—and clearing off some early Potatoes, to get in Brussels Sprouts and Scotch Cabbaging Kale. Dug down, also, some Strawberry-borders after being cleared of fruit, which borders are also supplied with dwarf bush Apple trees, and planted thickly with Colewort Cabbage, except for a square of 4 feet or so round the trees. We do not by any means recommend this hard cropping of fruit-tree borders; but must do has a language of its own, as with a small garden, and a continuous supply, there is little use to think of uncropped fruit-borders, however much you may desire them to be so. For all tender fruit the injury done is not so much owing to what the cultivated plants take from such a border as from the shade given, which keeps the soil cold; and as the surface is apt to become dry from the absorbing properties of the roots of the vegetables, or smaller fruits, as Strawberries, the roots of the trees are naturally inclined to go down deeper after moisture than is good for them.

Above we have spoken of clearing off the remains of the early Cauliflower, as in the very busy days of May and June, when every moment was valuable, heads were frequently cut, and the stumps left remaining until a slacker time could be obtained for their removal. In general, however, this is a bad, wasteful, slovenly plan—wasteful because the large leaves left on the stump continue to pump up for themselves much of the nourishing properties of the soil, as we found beneath such stumps the ground dry, and thoroughly permeated by roots, at the depth of 30 inches; wasteful, too, because they thus not only uselessly exhaust the soil, but the nourishment which the decomposed stumps and leaves would give to other crops is so much longer held in abeyance. The plan is slovenly, because, if followed in the case of a Cauliflower, it is apt to be followed in the case of Potato-haulm, Lettuces, &c., it being somewhat easier to cut a Lettuce than to pull it up and leave all that is not wanted for the table to give its nourishing properties to the rubbish-heap, and all such remains left in the garden give it an untidy appearance, conjuring up the ideas of a thorough cleaning-up day; whilst the prominent ideas in a well-kept garden should be constant tidiness, comfort, and elegance. Why should not a row or a bed of Cauliflower be

as interesting as a flower-bed? It has at least all the advantages of utility to recommend it. The cut-and-leave-stump system is also very deceptive to all but the individual who cuts. A quarter of Cauliflower which has been thus treated, seen at a little distance, would look a quarter of Cauliflower still. When the useless parts are at once removed, the superintendent or the proprietor can see what he has left, and take stock without an effort. From this cause alone we have known unpleasantness from circumstances that would be comical, but for the annoyance associated—such as gentlemen offering half a dozen or half a score of heads of Cauliflower to a neighbour, when he himself had not one left fit to eat.

This gossip about stumps of Cauliflower brings to our mind two questions that should have been answered a week ago. The first is, "What do you consider the best size for Cauliflower to be when sent to a gentleman's table?" We do not consider the question of size as of so much importance as the question of quality. Insure quality, and then size will be an advantage, for large parties especially. The larger the better, if the head is white, compact, firm, no floweriness on it, no openings, and forming about three parts of a solid ball. The same rule will hold good as to prize Cauliflower at shows. A large head, if at all open or flowery on the surface, or with open spaces between the parts of the heads, will be passed over, and the preference given to a smaller head if quite firm and compact. As to ourselves, for the parlour table we prefer compact heads rather under than over the ordinary size of a man's closed fist. When larger or beginning to open they are sent to the hall, and if they come in too fast even to suit rotations there, they are given in turns to the men who help to grow them.

This brings us to the other question from "A YOUNG GARDENER:" "My Cabbages are many of them beginning to split and my Cauliflowers to run because they come in faster than they can be used. Is it not a usual thing to give such vegetables to the labourers who choose to accept them? Would I not be perfectly right to do so?" We thoroughly approve of your intentions. It is a pity that what is fit for human food should be wasted; but if you wish to be safe you must dismiss from your mind all reliance in such matters on mere usage, and all feelings with respect to anything like right. The right alone rests with the proprietor, and if you are wise you will do nothing in the matter without receiving his full sanction. Even after this, such a commendable proceeding must be accompanied with prudence. After much observation and experience we consider that two things are essential. First, that you yourself see the vegetables thus distributed; and, secondly, that you take care that no more be given at a time than can be used at once by the receiver. There must be no inducement in the shape of quantity for the labourers to dispose of them. There are many high-minded proprietors who would not descend to sell, but who feel a great pleasure in giving to their friends, and who are very pleased that any surplus should be given to the workmen; but we have known instances of great mortification, unpleasantness, and even the giving up of a good old benevolent usage, because it came out that the workmen sold what was given to them.

Well, then, in return for what we consider prudent advice, we want some of our readers and friends to help us. Of all vegetables there is nothing that delights more in sewage water and manure water of all kinds than Cauliflower. We have a pump for one sewage tank, and the men as yet have never said anything about it, as we do not think they have ever found the smell offensive. But our own nasal organs are excessively sensitive, and we are not satisfied with anything we have done to render the sewage inodorous before it is committed to the earth. After that, the earth soon makes all right. Now, what we want is some cheap and easily-obtainable substance, and one, too, which would not interfere with the nourishing value of the water—a substance which would have the desired effect, either when thrown into the water or, better still, placed in the barrel in which the sewage is pumped. A short paper on this subject from a practical scientific friend, would, we are sure, be read with great interest. Perhaps a correspondent who gave us some good ideas the other week would be good enough to amplify on the subject. The great essentials are cheapness, retaining nutritive properties, simplicity and safety in the application,

so that a common labourer may use it safely, and the humble cottager may apply it to the hole in which he husband all his slops and washings for manure-waterings. We lately saw two plots of Cabbages in two neighbouring cottage gardens, those in the one plot having a light silty woe-begone appearance, with the leaves flabby, and little or no hearts, whilst those in the other plot had nice firm hearts, and a rich dark appearance in their foliage—a beautiful contrast to their neighbours. The kinds were the same, and the culture and treatment much the same, with this exception, that from one house all the slops were allowed to pollute the highway, and from the other the most of all that could be saved was put to the roots of the Cabbages. Some half a dozen plants had been burnt up by an overdose, but this was knowledge which would be valued in future, and lead to diluting slops when otherwise too strong. In all cases it is safest to use such waterings weak enough.

FRUIT GARDEN.

Much the same as in previous weeks. Notwithstanding the showers, have had to water some heavy crops of Queens and other Strawberries, as the flower-stems looked as if inclined to droop. Want of watering when there is plenty of bloom is the chief cause of Strawberries failing to produce well. The first-turned-out Strawberry plants from forced pots are now coming nicely into bloom, and will come in as successions to such late kinds as the Elton. In all small gardens the fruitful plants of such late kinds as Elton and Eleanor should be marked for runners as stated the other week, as barrenness is more apt to be transmitted from them than from some of the earlier kinds.

ORNAMENTAL DEPARTMENT.

Here it would take a long article to tell all the ins and outs of potting and repotting greenhouse and stove plants, fresh arranging with huge Balsam plants, Scarlet Geraniums, &c., looking over beds, fastening and training plants, so as to have all the beds full, so that they may not have that desert appearance until August, of which a correspondent spoke lately, and which is a common accompaniment of the present system of flower gardening. This and various other matters we cannot now allude to, farther than to enter a protest against the idea so currently gaining ground, that fine flower gardens, say from July, and comparative dreariness in the spring, are the fault of the gardening body. Let the burden be laid on the right shoulders. Let labour, material, and means be given, and with previous experience, and the help of Mr. Fleming's little book, there would be no difficulty in having gardens gay from spring to November at least. But the truth is, that in a great many places the energies of gardeners are already overtired to make the most of the bedding system for summer and autumn; and to fill the same number of beds continuously, say from March to the end of October, with the same means and the same expense for labour, is to attempt an impossibility, though the word impossible does not come much in our way. Where this extra expense cannot be afforded, and spring gardening is, as it ought to be, quite as much considered, and rather more valued than a blaze of colour from midsummer and onwards, then the right policy is not to grumble that the gardener cannot do this and that, however willing, but to curtail the extent of the planting, and thus to enable him to keep all in good order from spring to autumn. For this purpose a reserve garden and a great number of pots will be necessary, that when spring beds are removed they may at once be filled with plants in bloom.

One word as to thin and thick *planting of beds* in answer to two inquiries. Our rule would be to plant according to circumstances—that is, the common bedding plants, such as Scarlet Geraniums and Yellow Calceolarias. Where the finest possible show was desired in June and July we would put good plants in some 6 or 8 inches apart. Where the best display was wanted from August until frost came, then we would put in similar plants from 12 to 16 inches apart. It is true you may thin in the autumn those plants turned out thickly; but even then, independently of the trouble, they will not bloom so well generally as plants put in thinner, and that have thoroughly covered the beds without injuring each other. Circumstances, therefore, should regulate the thickness of our planting.—R. F.

TRADE CATALOGUES RECEIVED.

Smith & Simons, Argyle Arcade, Glasgow.—Catalogues of Dutch Flower Roots and Select Roses.

COVENT GARDEN MARKET.—JULY 9.

Supply good and demand brisk. Apples and Pears have made their appearance, the latter chiefly Jargonelle from abroad, and of these a few good samples may be obtained. Plums are coming in abundantly from the continent. Pines, Grapes, and Strawberries are very good and quite sufficient for the demand. Peaches and Nectarines are more plentiful and prices are reduced. Melons are rather scarce, but of good quality; Figs more abundant. Common Cherries are bringing from 4d. to 6d. per lb. Of Currants there is a good supply of all kinds. Asparagus is nearly over. The supply of other vegetables is good.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

PEACH TREE INFESTED WITH SCALE (*Old Subscriber*).—Dissolve 4 ozs. of gum arabic in a quart of water, and paint the infested parts with it by means of a soft brush. Allow it to remain on a few days, then wash it off by strongly syringing the tree with water at 120°. In winter after the leaves have fallen dress the tree with a solution formed by dissolving 8 ozs. of Gishurst compound in a gallon of soft water, and brush this well into the cracks and crevices of the wood, being careful not to injure the fruit buds.

GALLIC CULTURE (*Idem*).—Plant the offsets in rich ground in an open situation in February, and in rows 1 foot apart, and 6 inches from offset to offset in the rows. The drills should be drawn about an inch deep, and the offsets placed with their growing points upwards in the drill, and be gently pressed into the soil. When planted cover with an inch of fine light soil. Keep them clear of weeds, and when the tops turn yellow take up the roots, and tie them in bunches of about half-a-dozen, and suspend in any cool dry place.

GROWING CABBAGE SEED (*Idem*).—Sow the seed in April, pricking off the seedlings when strong enough, and finally plant out in rows 2 feet apart, and the same from plant to plant. Earth up and keep clear of weeds, and in autumn transplant into good rich deep soil and in rows a yard apart, and sufficiently deep in the soil to cover the stem to the lowest leaves. The Cabbages should be 2 feet apart. A sheltered situation is to be preferred. The plants will bloom in due time, and seed will follow soon afterwards.

SYRINGING VINES (*Idem*).—They may be syringed every morning before the sun becomes powerful with clear soft water, except when in flower, and after the Grapes change for ripening. It is, however, much more advantageous to syringe Vines at the time of shutting up the house in the afternoon, sprinkling the paths, &c., the following morning.

CUCUMBERS DISEASED (*F. C.*).—The disease which is so prevalent at present amongst Cucumbers and the Cucurbitaceæ family generally, is evidently of fungoid origin, the cause and cure of it being as yet concealed from scientific eyes. We know of nothing more likely to mitigate the evil than procuring sound seed from plants free from disease, and, after providing a mild bottom and top heat, to keep both sustained so as to make the plants grow freely; to employ soil that has been well exposed to the influences of the atmosphere, and moderately rich—that furnished by rotted turf being rich enough without any addition of manure or leaf mould; to renew the plants often, and when they have produced a fair crop and show symptoms of decreasing vigour, and it may be slight traces of the disease, to pull them up and throw them into the fire, and put in young plants in their places, having previously removed the old soil and replaced it by fresh sweet compost. We shall be obliged by any of our correspondents favouring us with particulars of anything they have found useful in remedying the effects of this disease, which threatens to become as great a scourge to the Cucurbitaceæ as the Potato murrain was to the Potato a few years ago.—G. A.

COTTAGE GARDENERS' DICTIONARY (*G. D.*, of *H.*).—Bohn's edition is the last. No supplement has yet been added.

ANTIRRHINUM AND OTHER SEEDS (*A Young Amateur Subscriber*).—Write to any of the great florists who advertise in our columns and ask them the same questions. They will readily reply. We never recommend tradesmen.

VINE LEAVES (*E. P. Hall*).—What you call an "eruption," only occurs on very vigorous Vines. It will not affect the crop. Keeping the house cooler, drier, and better ventilated usually prevents its occurrence.

CLOVER SEED (*B. H. W.*).—Some Clover seed is grown in all the counties of England where the climate is mild and the rainfall small; but it is grown most extensively, we believe, in Cambridgeshire. The largest quantity, however, is grown in the German States bordering on the Rhine, and it is exported chiefly from Hamburg; yet that which comes to England from Holland and Belgium has found its way thither principally from the German States. In 1861 there were imported into this country 198,120 cwt., in 1862, 168,974 cwt., and in 1863, 272,626 cwt. We have no means of ascertaining the quantity usually ripened in this country.

GROUND VINEY (*A. S. A.*).—For four penny postage stamps sent with your direction, you can have, free by post, the Number containing the plan and description. Or if you wait for a few weeks a Manual will be published at our office containing that and all other particulars relative to Vine-culture.

PLATYCERUM STEMMARIA (*H. A.*).—This is the Fern you mean, and though you saw it growing in a greenhouse it flourishes more vigorously in a stove. It is a native of Guinea and introduced in 1822. You will find it described in some botanical works as *Acrostichum stemmaria*. The usual treatment of stove Ferns is all that it needs.

MAKING ASPARAGUS-BEDS (*Novice*).—We prefer making the beds any dry time in autumn from September to November. It is not of much moment whether the ends of the beds are north and south, or east and west, but preference is given to the first when we have the choice. The plants should be two and not more than three years old. They should be planted in the last week in March or first week in April. Any nurseryman can supply you with the right kind of plants. We do not recommend dealers.

LAPAGERIA ROSEA CULTURE (*A Subscriber*).—It requires a compost of turfy peat with a little turfy loam added, abundant pot room, and perfect drainage. It requires watering every day from the time growth commences until it ceases, and double the quantity at a time to that given to a Fuchsia. It should be trained near the glass on the north side of a span-roof, or be slightly shaded if on a southern aspect. *Lastrea opaca* will do well in a cold greenhouse in winter.

STOPPING FUCHSIAS AND PELARGONIUMS TO BLOOM IN SEPTEMBER (*A Young Amateur*).—Fuchsias may be stopped until within six weeks of the time they are wanted to bloom, but to make sure if you stop them when this appears in print they will need no further stopping. Pelargoniums to bloom well in September should not be stopped after June.

ANTS (*A. J. H.*).—We do not think that they will injure either your Cucumber-roots or Mushroom-spawn. You may drive them away by sprinklings of guano or Scotch snuff. Were they in any other place watering frequently with gas ammoniacal water would banish them, but it might injure your crops.

MILDEW ON PEAS (*W. L.*).—On light soils the mildew may usually be prevented by manuring the soil liberally, mulching over the surface close up to the stems, and for foot wide on each side, with stable manure, and watering freely in dry weather. Dusting with lime we do not think will be of any use. More vigour requires to be imparted to the plants.

SWEET MACE (*Delta*).—The plant so called by the south Derbyshire cottagers is Tansy, *Tanacetum vulgare*.

EVERGREEN FOR INSIDE BACK OF GREENHOUSE (*B. G.*).—For a strong free-growing evergreen for the back wall of the greenhouse, but the flowers are inconspicuous, the *Ficus microphylla* or *capensis* will answer well. For evergreens with a profusion of sweet yellow and whitish blossoms, you could have *Jasminum revolutum* and *Jasminum gracile*. For evergreens in bloom all the winter and spring, and which rather like a little shade in summer, command us to the *Canellias*. They would grow capitally in such a raised narrow border.

DRYING ROSE LEAVES (*Hortus*).—Dry them for making pot pouri by placing them where a dry cold current of air can pass over them. The old Cabbage, Moss, and Tea-scented are the most scented.

VINES IN A PIT (*J. M.*).—There is no doubt whatever that the Vines will succeed planted in the pit and trained up its roof, if you drain the bottom of the pit, and prevent the roots of the Vines descending.

NAMES OF INSECTS (*J. S. S.*).—The insects in the pineries which seem to feed and breed in the tan, and do not appear to injure either the Pines or stove plants, are an exotic Millipede, closely allied to our British species, *Polydesmus complanatus*. They have, doubtless, been imported with foreign plants. These insects are generally considered to feed on decaying vegetable matter.—W.

MELON PLANTS SHEDDING THEIR FRUIT (J. M. Gileanach).—We think extra luxuriance is the cause of your Melons dropping, and so early. Lessen luxuriance by giving less bottom heat, no more water than will just keep the leaves from flagging, and plenty of air day and night, if at the latter period the atmospheric temperature do not fall below 65° and from that to 60°. No doubt the roots run too freely in your rich turf and cocoanut fibre. We are obliged by the information about Broom and caterpillars.

MUSA CAVENDISHII CULTURE (D. G.).—Your Musa Cavendishii is doing well. Eighty fruit is a goodly number to swell well, and Nature seems to be doing what she expected to get some help in doing. A higher temperature, of from 75° to 85°, will not cause more fruit to set, but thinning them much may do so. When your plant has fruited, it is best to encourage it to make a sucker or two; then take it up, detach the young plant, plant it in new fresh soil, and ere long it will rival its parent. This is a better plan than keeping the old stumps. It is not common yet to have fruitful cones on the Wellingtonia.

NAMES OF FRUIT (Thomas Record).—The Strawberries we should say are both Keens' Seedling, but it is impossible to tell from a few fruit only, particularly as there are now so many sorts very similar to that variety. The Grape is Black Prince. (*John Crofts*).—No 2, Elrige Nectarine; 3, Barrington; 5, Royal George. We got in confusion with Nos. 1 and 4. That which is quite pale at the stone is Noblesse, and that which is red is Red Magdalene.

NAMES OF PLANTS (W. H. Mayne).—The white flower is a Watsonia, not a Gladiolus, but we cannot say which species without seeing the plant. The shrub is Ozothamnus thyrsoides, D. C. (*V. Z.*).—1, Lastrea decurrens, J. Sm.; 2, Lastrea diatata, Presl., perhaps the variety Standishi; but the specimen is too young to enable us to speak with certainty; 3, Erinus alpinus; 4, Begonia, we cannot say which species, for there are upwards of 350 known to botanists, and none of them can be accurately named from a single withered leaf; 5, Litobrochia vespertiliois, J. Sm.; 6, Selaginella cuspidata, Link. (*S. H. W., Reading*).—1, Lastrea spinulosa, Presl.; 2, L. Filiix-mas, var. paleacea, Moore. You will find Lastrea rigida in the "British Ferns," published at our office. L. quinquangulare is not in either of our Fern books, and we cannot refer you to any English description of it. It is said to be from West Africa, and is allied to L. decomposita, of which, indeed, some authors consider it a variety. It was first named and described by Kunze in the volume of the "Linnaea" for 1850. (*S. A. P.*).—1, Impossible to name the Lobelia from such a miserable scrap; 2, Farsetia suffruticosa, D. C.; 3, Cerastium tomentosum, L.; 4, Phlox maculata, var. candida, Bth.; 5, Helianthemum, sp. (*Marple*).—1, Polystichum aculeatum (both); 2, too young to be recognised; 3, Alchemilla vulgaris, L. (*W. L.*).—Cladrasis tinctoria, Raf.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY CLUB JUDGES.

I HAVE a letter before me from Mr. Hewitt, stating that he communicated to you privately respecting his being a judge to the Poultry Club, and how you can justify the way in which you have published the correspondence I am at a loss to know. The whole tenor of your remarks appears to have no other object in view than to attempt to injure the proceedings of the Poultry Club, in proof of which, I beg to quote the following extracts from Mr. Hewitt's letter to me, dated 30th June :—

"I can assure you that it is impossible for any one to feel more annoyed than I do at the paragraph in question, nor could any one be more astonished. About the date of your first letter I received from Mr. Dolby two letters, requesting me to aid the proposed Islington Show, by a notice in THE JOURNAL OF HORTICULTURE. I wrote one, as customary, sent it in a separate letter; but even then, well knowing there was a good deal of 'ear-wiggling' going on from the rear against the Club, I wrote another letter to the Editors, explaining privately that in my case the restrictions of rules were removed. This letter was itself headed 'private,' twice dashed, and even the envelope similarly endorsed. By the next morning's post I received so very extraordinary and extreme a reply of disapproval, that I actually went up to London. I wrote a second, very much shorter, simply stating particulars of the prize list. This, too, was virtually refused, and in lieu of it eventually the paragraph appeared in print that is justly complained of." See THE JOURNAL OF HORTICULTURE of the 28th of June.

Such an uncalled-for publication of a private and confidential correspondence appears to me to be a great breach of faith.

Wishing to secure the services of such an upright Judge as Mr. Hewitt, I was anxious to make any sacrifice to meet his views, and the offer to waive the rules was merely a tribute to the great ability and acknowledged experience of the greatest poultry judge in the world—a tribute which no other judge may ever expect.

Allow me finally to state that three members of the Club have consented to act as judges, who have been the most extensive breeders and successful exhibitors in the kingdom; so that you will find, probably, not as you imagine, that the

rules of the Club are inoperative, and their application an impossibility, but the reverse.—EDWD. TUDMAN, *An Hon. Sec. to Poultry Club.*

[We very readily insert this communication. It is quite true that Mr. Hewitt's letter was marked "private," but as we had seen him subsequently, and stated the substance of what we should say in the first notice of his appointment, and to which he did not object, we considered it only due to him to state what we did in our second notice. We think the Club quite right, as you say, in securing the benefit of his great ability and acknowledged experience, and we are quite sure he will act independently.

So far are we from wishing to injure the Poultry Club, that we hope it may succeed in establishing many exhibitions, and that the awards of the judges it appoints may be satisfactory. What we object to is any competent judge (and no other should be appointed), being bound to adhere to rules rather than to the dictates of his own experienced judgment.]

REARING CHICKENS AND DUCKLINGS.

I SYMPATHISE with "A. K. C." as to the loss of his Dorking chickens. The boundless range and over-feeding are most likely the cause. I have found, in breeding poultry, that the Dorking and Spanish are the most difficult to rear. "A. K. C." will do well to confine his chickens, with the hen, in a coop, away from old dead rotten wood, and not where fungi and worms abound. Feed them upon rice boiled with milk, and, as a change, give sharps and oatmeal mixed with milk, the milk to be sweet; skimmed milk will do.

"A FARMER'S WIFE" will do better to keep only one drake to six Ducks. Kill one of the drakes, and if she likes keep one of the young ones of this year's brood. I have one drake to four Aylesbury Ducks. My troops of young Ducks range from sixteen to thirty-two; ninety-nine in all, out of 132 eggs. All are fed with boiled rice and meal.—J. D.

POULTRY JUDGING.

Who is not glad to see "WILTSHIRE RECTOR," whether it be in his practical remarks, or his New Year's Eve Dream? I read, and read again, and, on seeing "WILTSHIRE RECTOR" at the end, am generally disposed to agree to all he writes; but in his "Rules for Poultry Judging," I cannot go with him. I have thought this subject over once and again, but I do not see how you are to make the living individuality which goes to make up the judge merge into the machine, which he must become if he is to judge by a certain code of rules, with which, possibly, he may not agree.

On a matter of opinion, it is difficult to force any person to act contrary to his own notions. But, go further—frame your rules, place them in the hands of every poultry-breeder, and it must still rest with the judge to determine: it is his individual opinion which must decide the merits—whether, for instance, that pen which is evenly matched is not more entitled to the coveted honour than that which has one or, perhaps, two perfect birds, agreeing to the "code of laws" in every particular.

Again, the value of the points in each separate bird must be considered as minutely as the Chinese painter measured the distance between the small-pox marks on the old gentleman's face, that he might transfer them to the canvas intended for presentation to his lady love. What reception will this minuteness receive at the hands of unsuccessful exhibitors? Why, very much like that bestowed on the poor Chinaman, who was unceremoniously kicked down stairs by his rather testy sitter when the discovery was made. It is "agin natur," as Sam Slick would say, for others to discover faults in birds, whose faults, by constant glossing over, we the owners have learnt rather to like than otherwise. This, perhaps, applies much more closely to "exhibitors in a small way;" we have not the unlimited means to buy the perfect specimens, and must in some measure be content with what we can produce.

When "WILTSHIRE RECTOR" says, "I have heard an exhibitor remark, 'I do not know whether I shall take any prizes at this show; they depend upon who is the judge. Mr. A. likes my sort of birds, &c.'" This may be so; but

"WILTSHIRE RECTOR" and "the exhibitor" both seem to forget that it is not always the same pens or the same exhibitors who compete: that even supposing they do, the condition of the pens may have altered. It reminds me somewhat of my man Friday; although he really does attend thoroughly to my poultry, yet he hates cordially all "vowls," wishes "measter 'ud tell he to wring all their necks, shouldn't have to tell 'un twice." Although he dislikes the "vowls," he has no objection to a slice of prize money, and owing to sundry windfalls in this way he has learnt to appreciate my Brahmans. The wind, however, changed, and instead of prizes came commendations and high commendations. I do not blame the judges or wish for a code of rules, &c. I like prizes—who doesn't? but Friday intimated, "Thick thur judge up theer warn't much of a judge not to gie the big cock a prize;" and a few days after when the next dose of high commendations arrived, he remarked, "Thick thur zort of vowl be gwinne out o' vashion, be'ant they?" I strove to convince him that there were better birds there, but I fear I did not succeed. I am sure he thinks the powers of the judge in question very limited. "WILTSHIRE RECTOR," perhaps, recollects that a few months back there was a great talk about the Poultry Club; a code of rules seemed about to appear directly. Where are they? Have the members found it impossible to frame them to satisfy all? I know by experience it is not pleasant to lose, but, as Hood says, "What can't be cured must be endured." We have, by somewhat general consent, arrived at certain landmarks; and, after all, I imagine, wrongly perhaps, that something is necessary to make the good judge that no rules can give—something, in fact, which is inherent in the judge himself, and not in any rules, however good. Certain points appear settled—thus even matching and condition in all pens, whatever the breed; a certain form of comb in some breeds, a variety in others; size, large in some, small in others; a certain character of feathers in a variety of breeds, which may be styled "birds in feathers;" a clean leg in some, feathered in others. Such general points, with others, we all know, or ought to know. Were we to know much more it would be contrary to experience to obtain universal satisfaction. Each judge must see with his own eyes, and mentally make his own calculations as to the relative merits of competing pens. It would add immensely to the labours of a judge if at each pen he must, with pencil in hand, make a calculation of points; and I am rather disposed to believe that the best judges of the present day would not judge under such conditions.—Y. B. A. Z.

PAIR OF HENS OF ANY OTHER BREED.—Prize, T. E. Kell. Commended, W. Cannan; T. B. Ireland.
GESE.—First, O. A. Young. Second and Commended, W. K. Goodbarne.
DUCKS (Any variety except Aylesbury).—First, O. A. Young. Second, W. H. Park, Mewton Kyme. Commended, W. Cannan.
DUCKS (Aylesbury).—First, W. Cannan. Second, O. A. Young.
TURKEYS.—First, W. Cannan. Second, Miss Walton, North Milford. Commended, Mrs. Blacker, Healaugh.

DOMINIQUE FOWLS.

THIS variety is, very justly, becoming popular where best known, especially for hardiness. We find the following description of it in a very valuable article upon poultry, in the late report of the Department of Agriculture.

"The Dominique is the best fowl of common stock that we have, and is the only fowl in the country that has enough distinct characteristics to entitle it to name. These fowls are full medium size, being but little less in weight than the Dorking, have full breasts, rounded full bodies, double or single combs, and yellow legs. Their main plumage has a light grey ground colour, while each feather is barred cross-wise with a darker shade. They are frequently known by the name "Hawk-coloured fowls." They are hardy, easily raised, retain their peculiarities with great tenacity, have yellow skins, a colour preferred by many for a market fowl; and taking these fowls all in all, they are one of the best varieties in common use."

The flesh is good and they are fine layers. They roost high, and hence are not in the way like the lazy Asiatic fowls.

The Black Spanish are most beautiful fowls, but a winter like the past is very disastrous to them. Undoubtedly, with extra care in winter, they are the best layers in the world; but we would not recommend them for the general fowl of the farm by the side of the Dominique. The Spanish for a village or city are first.

To substantiate our estimate of these fowls we will state that Mr. Wentworth, who has experimented with almost every known kind of fowl, has abandoned all others, and is now starting with the Dominique.—(*Prairie Farmer*).

HEN PHEASANT ASSUMING THE PLUMAGE OF THE MALE BIRD.

THIS change of feather is not nearly of so rare occurrence as many suppose it to be; and as the subject is now before the public, I willingly add my own experience to the statements of others already published.

Some five and twenty years back I obtained a brood of young Pheasants, which after a time became exceedingly docile and familiar. Without exception they proved of the general common feather. A portion of them I kept by me for many years. The hens all laid well, and the eggs proved fertile when placed under common fowls. Matters went on in this way for some ten years or more, when I found one of the hens become exceedingly pugnacious, ill-treating alike both her female and male companions. She ceased laying altogether, or rather did not commence laying at all at the customary time, though the others were as productive as heretofore. Her worst feature now was, she ate every egg she possibly could obtain of the other Pheasants, and this caused me to remove her to run with some fowls, whose eggs she also took a fancy to, with a zest equally depraved as when in the company of her fellows. It was when taking her from her original pen that I first perceived she was assuming the feather of the cock bird. It showed the first year chiefly about the neck and head, the breast also becoming of a peculiar ruddy hue. That first moult, too, the tail-feathers were evidently much longer than in the other hen pheasants; and during the three or four years I afterwards kept her she gradually altered more and more to the cock's plumage. At length she became so indomitable a virago as to allow no other bird of any kind to live in the same aviary. She was then killed, and I still have her preserved. The head and neck feathers are precisely the same metallic bluish green as a cock's would be, but she never assumed the coral velvety appearance round the eye as in the cock. Her breast is of the ground colour of a cock, but devoid of the black markings. The back and tail feathers are still much

SELBY, TADCASTER, AND MARKET WEIGHTON AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE eleventh annual Exhibition of this Society was held at Tadcaster on Friday, the 1st inst. There was a good show of poultry, comprising about 150 pens. The prizes were awarded by Mr. Geo. Jackson and Mr. Alex. Cattley, of York.

SPANISH.—First, M. Kidd, Tadcaster. Second, W. Houseman, Tadcaster.
Chickens.—Prize, F. Powell, Knaresborough.

DORKINGS.—First, T. E. Kell, Wetherby. Second, T. B. Ireland, Tadcaster.
Chickens.—Prize, J. E. Kell. Commended, Mrs. Oliver, Bolton Lodge, Tadcaster.

COCHIN-CHINA (Any colour).—First, W. Cannan, Bradford. Second, R. Dewes, Knaresborough.
Chickens.—Prize, R. Dewes.

MALAY.—First, O. A. Young, Driffield. Second, withheld. **Chickens.**—Prize, O. A. Young.

SINGLE GAME COCK.—First, R. Bickers, Beverley. Second, T. B. Ireland.
PAIR OF GAME HENS.—First, J. Harrison, Holbeck, Leeds. Second, T. B. Ireland.

GAME CHICKENS.—Prize, J. Barker, jun., Dunnington, York.

HAMBURGH (Golden-spangled).—First and Second, W. Cannan. Commended, G. Holmes, Great Driffield. **Chickens.**—Prize, C. Snowdon, Tockwith.

HAMBURGH (Silver-spangled).—First and Second, W. Cannan. **Chickens.**—Prize, W. Cannan.

GOLDEN-PENCILLED HAMBURGH COCK.—First and Second, W. Cannan.

HAMBURGH (Silver-pencilled).—First and Second, W. Cannan.

CHIUTEPRAAT OR CORSCIAN.—First, W. Cannan. Second, withheld.

POLANDS.—First, W. Cannan. Second, O. A. Young.

ANY OTHER VARIETY.—First, F. Powell (Brahmas). Second, W. Cannan (Black Hamburgs). **Chickens.**—Prize, Mrs. Moore, Boston Spa (White Dorkings). Commended, F. Powell (Brahma Footra); H. Lacy (Brahma Footra).

BANTAMS (Any variety).—First, T. E. Kell (Game). Second and Commended, Lady Londesborough (Golden). Commended, W. Cannan (Golden).

COCK OF ANY OTHER BREED.—Prize, W. Cannan.

the colour of the hen Pheasant, but her tail had each year become longer and longer, till the principal feathers reached that of a male bird. They are peculiar, the shaft of the longest feathers being somewhat depressed.

A neighbour of mine had also a hen English Pheasant that changed its feather in the same way, but to a much greater degree, a few years after: indeed she, when living, looked at first sight like a young cock. She, too, became furious to other birds, and an inveterate egg-eater. When I last saw her she was closely approaching a clear blotting-paper colour, and had very slight markings on the breast, towards the crop only. She, too, was an old-reared bird.

From what I have now stated alone, facts seem to carry out the supposition that all such birds are old birds, and in several shot Pheasants of like character they were evidently aged specimens. It is well here to mention, that in all cases I ever narrowly examined, the ovary was much diseased, though the bird showed well as to flesh or feather—in fact, appeared like an expressly fatted fowl. But I must briefly mention another case of a somewhat different character.

I once hatched a young Pheasant that at her first moult, long before she had arrived at laying time, became of the questionable feather referred to; but as she consumed every egg within her reach, and was the worst of neighbours to all others, as time drew on her last appearance was on the dinner-table, devoid of all outward peculiarities. I also have known the same fact in a fowl, a Sebright Gold-laced Bantam hen, from whose eggs I for years reared many chickens of excellent markings. At one moult she obtained partial sickle feathers with a hackle and saddle feather that would be held as abominable in this particular breed; yet prior to this moult so perfectly feathered had she been, that at three different Birmingham shows she figured in the first-prize pen. Her spirit of ill-will was then similar to the Pheasant's before named, and as I wanted eggs (though she never laid after her change), and she ate all other eggs at hand, I gave her to a medical friend, who, on examination after he had killed her, found a diseased ovary, as I had anticipated would be the case.

In conclusion, it appears that all such birds are useless and very expensive as hobbies if allowed the run with others, and therefore it is expedient to put them aside as soon as this strange freak is first manifested.—EDWARD HEWITT, *Eden Cottage, Sparkbrook, Birmingham.*

ARTIFICIAL SWARMING.

THE following account of my first and successful attempt at making an artificial swarm may, perhaps, interest some of your readers, as it took place under peculiar circumstances.

In May last I received a hive of Ligurian bees from "A DEVONSHIRE BEE-KEEPER." Early in the morning of the 4th of June I found the queen in a dying state on the alighting-board, and the bees passing in and out over her body with the most perfect indifference. On the 13th several young queens were heard piping; but day after day the weather prevented their swarming. On the 16th they attempted to come off, but the high wind drove them back again. The next morning I expected to find the supernumerary princesses thrown out; however, they were still piping, and the weather was wet and cold, so I determined to divide the bees.

The stock which I shall call A was taken to an unfurnished room, and placed at some distance from the window. An empty hive, which I shall name B, was placed in the window. Both hives are made on the Woodbury plan. I removed the crown-board from A and puffed in some smoke; then, taking out a frame from the middle of the hive, I carried it to the window and found it contained what I wanted—a royal cell with a piping queen in it, and a fine young queen at liberty on the comb. This young lady I captured and returned to A. Having fixed the frame in B, and placed the crown-board on, I proceeded to brush a sufficient number of bees off the bars of A to keep the brood warm during the night. Then I placed the crown-board on A, closed the entrance, collected with a feather the bees which were trying to get out of the window, and placed them at the entrance of the hive. They all settled in before dark, and

the hive was placed in the house which A had occupied, and A conveyed to another part of the garden. The next day was fine, and all the bees that left A went to B, which by the evening contained a good swarm, and a sufficient number of bees were left behind to carry on the work of the hive. The young queen in B piped for about two hours, and the piping continued in A until the next evening, when a fierce slaughter of the drones took place, and continued until all were lying dead on the floor-board, from which I swept them the next day. The bees in A have not settled down to their work as I could wish, and there appears to be a nervous timidity about them. They seem afraid to leave their hive, guarding the entrance against some foe, and disputing the passage of their own bees into the hive. A little pollen is carried in, but they leave off working early in the afternoon. I do not think anything can be wrong with the queen. I found two young grey bees on the alighting-board yesterday morning, and some drones that appeared after the great slaughter were worried. I think this nervousness must have been occasioned by the unaccountable desertion from their hive. Have any of your readers met with anything similar to this? The young queen in A is much darker than her mother was, whom, no doubt, she had slaughtered.

If I ever perform an operation of this kind again I shall provide myself with indiarubber gloves, as I was very much stung through my dogskin. The moment I moved the frame I was attacked most savagely, and my left hand was very much swollen the next day.

This is the second instance I have known of young queens having been kept beyond three days. I once had a hive that swarmed on a Monday early, having been kept back by the weather on the evening when piping commenced, and they piped until the next Sunday, when they swarmed. The whole of the week was wet and cold.—J. L.

[The cessation of honey-gathering in A is owing to all bees of sufficient age for this purpose having deserted it, and returned to the old spot. Time will set this right. The young queen will become much lighter when, as a matron, she is expanded to her full size. "A DEVONSHIRE BEE-KEEPER" says, "Apologise for having misled this lady so much as to induce her to use leather gloves," and we do apologise; and as bees do not sting us through our gloves, we can only conclude that the skins of Editors are very thick—and so they need to be.]

FLOWERS FOR BEES.

THE following notes are published in reply to a correspondent, "A YOUNG BEE-KEEPER":—

BORAGE is probably the best of all bee flowers. It flowers in July (earlier if self-sown), on through the summer until cut off by autumn frosts, and is an annual. It should be sown in an open situation in beds 4 feet wide, and as long as desired, sowing the seed broadcast, about an inch apart over the surface and then throwing the alleys out over the beds, so as to cover the seed with from a quarter to half an inch deep of soil. A sowing made the first week in March, and another the second week in April, will afford a supply of flowers in most seasons from June until November.

MIGNONETTE.—Sow the seed the first week in April in beds as described for borage, only it should be sown more thickly, and be only just covered with light fine soil. It flowers in July onwards through the season.

SALVIA NEMOROSA.—An herbaceous perennial with blue flowers. It is readily increased by divisions of the root, which should be taken off, or the old stools or plants divided, in March, planting the offsets like Sage slips in rows 2 feet apart and 1 foot from plant to plant in the rows; or they may be planted in four-feet beds with one-foot alleys between, and three rows in a bed. It delights in a light gravelly soil, but will grow in almost all soils and situations. Planted on sunny hedgebanks, and on the borders of woods it grows well, being not only useful for bee forage but highly ornamental. It should have an open situation, and after the stems decay they should be cut down to the ground, and a little leaf mould or any waste vegetable refuse placed around the stools between the rows, which should be neatly forked-in in the April following. Beyond keeping clear of weeds

it needs no further attention. It flowers from June to October.

CROCUSES.—The bulbs of these should be planted in rows by the sides of walks, 1 foot apart and about 3 inches deep, in October, or in clumps, of three, five, or more together. Planted in sunny situations in shrubberies they add a charm to such places, and will grow well in all soils. Light soils, however, are preferable. They need no care beyond taking up once in three years, and dividing, planting a number in the same place again the same day, and others on hedge-banks, in fact anywhere not much overshadowed by trees. They should be replanted and divided in October.

SINGLE BLUE HEPATICA.—These, like crocuses, will grow anywhere in open situations, and are increased by division of the plant. They are best divided in autumn after the foliage decays, parting them so that two or three crowns are left to each division, which may then be planted in rows 1 foot apart, and the same distance between the rows. They should be planted so that the crowns are level with the surface. In future years it is only necessary to place a little fresh soil or waste refuse of any kind between the rows, to dig or fork it neatly into the soil, and divide the plants when too large for the allotted space, and replant. They flower early, often in January, and last a long time in flower. We have seen them in April. Crocuses usually flower in March and April.

BEES IN AUSTRALIA.

ENGLISH apicians will probably be interested in the following extract from the address of Dr. Bennett, delivered before his Excellency the Governor (Sir John Young), and others, at the annual meeting of the Acclimatisation Society of New South Wales, on Monday, April 4th, 1864.—G. F. B. Spalding.

"The English-imported bee has nearly driven away the small Australian stingless species, and the recent introduction of the Ligurian bee will be a great acquisition to the colonies, being very prolific, and yielding a larger supply of honey and wax than any other species; and the rearing of bees has the advantage of requiring very little capital, and but a small amount of labour. The quantity and value of the honey and beeswax produced in the colony is very great, and the latter has lately been exported to England at a remunerative profit."

A footnote in the *Sydney Morning Herald* adds the following:—

"I have been informed that the small black stingless bee in Australia has sometimes been seen in close proximity to the English bee, both having formed their nests in the same hollow of a tree, being only divided by a mud partition. When in that position one or the other lose their brood; they attack each other, and the Australian bee contrives to cut off the wings of the English bee. The honey from the native bee has a more agreeable acidulous flavour than that produced by the naturalised English insect."

SUCCESSFULLY LIGURIANISING AN APIARY.

HAVING had a beautiful Ligurian queen sent to me last September, I removed the English queen from a common stock of bees in one of my improved observatory-hives, the four sides and the top of which are of glass, and placed her at their head. She immediately commenced laying worker eggs. I examined the combs on the 9th of October, and found many young Liguriants hatched, and the queen still laying eggs. In none of my common stocks could I find any eggs on that day. This, I thought, was a very convincing proof of the great superiority of the Liguriants over the English queens in their prolific powers. The stock passed through the winter in the best possible health. The hive was exposed in an open latticed arbour, without any cover over the glass; and the thermometer inside of the hive, observations of which were taken three times each day, indicated a mean temperature of 3.88° in December, 3.90° in January, and 4.55° in February, higher than the mean temperature inside my other hives.

March 14th.—I cleaned the floor-board for the first time,

and only found two dead bees. I had not before seen a single dead bee upon it during the whole winter.

April 20th.—I commenced my Ligurianning operations by removing the queen out of one of my English stocks, and gave to it two Ligurian combs filled with eggs and brood. I also removed all the drone brood and cells out of thirteen common stocks.

April 22nd.—Examined the two Ligurian combs, and found no signs of any royal cells commenced (second day).

April 25th.—Examined the two combs and found the bees had about half made a royal cell on each comb, but only one of which contained larvæ, the other cell was empty (fifth day). They had also about half made three royal cells on the next comb, which was entirely empty.

April 27th.—Examined the two Ligurian combs and found the cell containing the larva enlarged. They had about half made another royal cell on the other comb, and the one previously made was in the same state as it was on the 25th, neither of them contained eggs or larvæ. The bees had also constructed four more royal cells on the empty comb (seventh day).

April 29th.—Examined the combs and found the larva in the royal cell nearly straight, and the bees about finishing the closing of the royal cell (ninth day). The two cells on the other comb, and the seven royal cells on the empty comb, were in the same state as on the 27th. I put another comb, containing drone and worker brood and eggs, into the hive out of the Ligurian stock, and I also placed worker eggs out of it into the nine empty royal cells, but I afterwards found that the bees removed all of them again.

This is only the account of the operations with one stock, but the end of it all was, that on the 31st of May I had beautiful Ligurian queens at the head of fourteen stocks, and had also hatched many more Ligurian queens than I required. On that day I made my first Ligurian swarm artificially, a very large one, and that night they had their queen hatched, and have done very well since.

My great difficulty has been to prevent a single common drone being hatched in my apiary. About every ten days I examined every comb in each hive, and removed all the drone eggs or cells that I found the bees had made. I shall now be able to keep the Liguriants pure, as I have only Ligurian drones in my apiary, and there is not a single common stock within about three miles. Thus I shall not have the same difficulties to contend with in keeping them pure that Mr. Woodbury has, as he is surrounded by common English bees. My old Ligurian queen is the finest and most beautiful one I ever saw, and she has certainly done wonders in laying eggs this spring. By the middle of May I had removed from her no less than twenty-two combs nearly filled with worker and drone brood and eggs, and the hive is crowded with bees quite ready for swarming.—W.M. CAEE, Clayton Bridge Apiary, Newton Heath, near Manchester.

TRY A "BEE-BOB."

MR. LANGSTROTH says, "Having noticed that a new swarm will almost always alight where they see a mass of clustering bees, I find that they can be determined to some selected spot by an old black hat, or even a mullen stalk, which, when coloured black, can hardly be distinguished at a distance from a clustering swarm. A black woollen stocking, or piece of cloth, fastened to a shady limb in plain sight of the hives, and where the bees can be most conveniently hived, would probably answer as good a purpose. Swarms are not only attracted by the bee-like colour of such objects, but are more readily induced to alight upon them if they furnish something to which they can easily cling, the better to support their grape-like clusters. By proper precautions before the first swarms issue, the bee-keeper may so educate his favourites that they will seldom alight anywhere but on the spot which he has previously selected. The Rev. Thos. P. Hunt, of Wyoming, Penn., has devised an amusing plan, by which he says that he can at all times prevent a swarm of bees from leaving his premises. Before his stocks swarm he collects a number of dead bees, and stringing them with a needle and thread, as worms are strung for catching eels, he makes of them a ball about the size of an egg, leaving a few strands loose. By carrying,

fastened to a pole, this 'bee-bob' about his apiary when the bees are swarming, or by placing it in some central position, he invariably secures every swarm."

I wish some of my aparian friends would try a "bee-bob" of some kind, and report results in THE JOURNAL OF HORTICULTURE.—A DEVONSHIRE BEE-KEEPER.

APIARIAN NOTES.

A RULE TO ASCERTAIN THE LOSS OF QUEENS.—Soon after they swarm, the queens when on a bridal trip, and are enjoying the society of the drones, as they course through the air, become so intoxicated with their amorous enjoyments as to be confounded on their return. Not recognising their distinctive homes, they mistakenly land in a foreign colony, only to meet a sudden death by the subjects of a queen, whose jealousy prompts them to the attack. Should we inspect a hive about this time, and find no eggs or brood, it is proof positive that it has no queen. The usual time for this is about twenty days after the issue of the first swarm. Again, if the bees allow the drones to remain in the hive long after the general massacre—say to the 1st of September or October—it is a never-failing sign that the queen is wanting, or that she is in an unhealthy condition. In such a state the stock should be supplied with a queen immediately, or united to another.

RULES FOR PURCHASING BEES.—Select two-year-old stocks of large size, that swarmed the previous year. It has been demonstrated that such stocks have young and vigorous queens, and are generally well-conditioned, promising a healthy generation. A very old stock should be rejected, even if it swarmed the year before and contained a yearling queen, for the obvious reason that the bees, having been bred in the old contracted cells, will be found of small size and insignificant in numbers. If you take your hive away to get a swarm placed into it, always purchase the first or prime swarm, and see that it is given you. Do not be put off with a second or late swarm. Choose a stock to commence with as you would choose a wife—get the best you can find. If you obtain one in the old box-hive invert it, and secure the bees by a cloth tacked securely over the bottom. Take it home when the air is cool, attend to it regularly, obey the directions as given, and then congratulate yourself as having started right.

In the purchase of bees there are many things it is well to observe. Remember if stock-hives are to be procured, ascertain the age of the queen. To select a young healthful mother seems to be a forward step towards a vigorous progeny.—(*Flander's New Bee-book, American.*)

FOUL BROOD AND DYSENTERY.

As it is the desire of some of your correspondents to learn from different observers their experience of foul brood, I give you what has come under my notice regarding it during the last few months. The first case was a hive that was much diseased, and was broken up in autumn, and the contents given to a healthy hive for the very purpose of proving infection, by "A STEWAETON APIARIAN," and no bad result has accrued therefrom since. The hive is all but healthy. The second is a hive in my own apiary which was almost reduced to a mere handful in the spring from what is termed dysentery. But I differ a little in my opinion, thinking it rather an overgorging, or feeding in winter more than they ought to do, in consequence of sudden changes of temperature arousing them to activity and causing them to feed oftener than would have been the case had they been shaded from the sun. At all events I have never found those attacked that were thus shaded. The bees were not able to fly, falling in hundreds on the ground, and leaving their excrements in the hive until it was thoroughly polluted. I took the advantage of the first fine day and turned the hive up to the rays of the sun for an hour and half till the bees were perfectly dry and able to fly. I then removed all filth, and took away one stock-box (it being in a square bar-and-slide hive), leaving in it one box only. It immediately commenced breeding, being about six weeks earlier than the majority of hives here. The spring this season was backward until April, the weather then continuing favourable till the 17th of May,

when it took a turn and continued increasing in cold till the 31st, when it appears to have reached its climax. The frost on the 31st of May and 2nd of June was so severe that icicles were suspended from the roofs of the bee-houses and covers, whilst the ice was an eighth of an inch thick, and newly-wrought ground was penetrated half an inch, so that all tender plants and the Potato crop have suffered severely.

But I must return to the condition of the hive. It had not been long in the breeding state when I found there was something wrong from the strong effluvium emitted. I immediately turned it up and examined it, when I found it in a backward state, with foul brood, and the bees scattered throughout the whole hive, evidently paying all the attention they could to the scattered brood. I used no means whatever to restore it farther than cutting out some of the worst combs for microscopical examination. This forced the bees to concentrate themselves, having very few combs for the queen's peregrinations, so that at the present time it is in a very thriving state and has got additional room. I am not, however, oversanguine of its future prosperity, but if spared I will report to you how it gets on.—A LANARKSHIRE BEE-KEEPER.

[“Who shall decide when doctors disagree?” In illustration of this adage we quote the following paragraph from a letter recently received from an able and highly-valued aparian correspondent in the adjoining county of Dumfries:—“The past winter has been cold and changeable. We had occasionally severe frosts, but at no time in this county above an inch depth of snow. On the 14th December, the bees in hives exposed to the one-o'clock sun got all out and evacuated. Those shaded remained within and were obliged to remain till after the middle of March. The consequence, as might have been expected, was dysentery, and, in most instances, destruction.”]

Foul-breeding stocks should be isolated as much as possible in order to prevent the disease from spreading to others. Yours appears at present to be what Dzierzon terms the mild and curable type. Take heed lest it degenerate into the virulent and incurable.]

HOUSEHOLD RECIPES.

SOILED CARPETS.—When soiled, carpets may be cleansed after beating with the following mixture:—Two gallons of water, with $\frac{1}{2}$ lb. soft soap dissolved in it, to which add 4 ozs. of liquid ammonia. This may be rubbed on with a flannel cloth, and the carpet then rubbed dry.

CEMENT FOR THE MOUTHS OF COOKED BOTTLES.—Melt together $\frac{1}{2}$ lb. of sealing' wax, the same quantity of resin, and 2 ozs. of beeswax. When it froths, stir with a tallow candle. As soon as it melts, dip the mouths of the bottle into it. This is an excellent thing to exclude the air from such things as are injured by being exposed to it.

OUR LETTER BOX.

PREVENTING SWARMING (*An Amateur, Preston.*)—Raising the hive on an eke 4 or 5 inches deep may prevent its swarming, or if the bees will work in a bell-glass it may have the same effect. Payne's improved cottage-hive is good and cheap, and may be obtained of Messrs. Neighbour. Buy "Bee-keeping for the Many," price 4d., free by post from this office for 6d.

BESIDES OUTSIDE HIVE (*Gardenia*).—The entire colony appears to have taken up its quarters outside the hive, and not merely thrown out a swarm as you imagine. During the middle of a fine day we should disperse and quiet them by the means of a little smoke, cut off the combs (keeping a sharp look-out for the queen), and fit them into a frame-hive into which we should then sweep the bees. If you cannot manage this, we see nothing for it but to destroy them in the autumn and appropriate their stores.

BEES—QUEENS, &c. (J. M.).—It is impossible to say exactly what amount of delay from bad weather or other causes may suffice to compel a virgin queen to lay eggs and thus become a drone breeder. On one occasion I knew impregnation deferred a month without injury. A month after the issue of the last swarm the presence of a queen may be ascertained by driving the bees into an empty hive and inspecting the combs. If sealed brood be found the stock is, of course, all right; if none can be seen it is, probably, queenless. If you cannot drive bees you may, perhaps, obtain a sufficient insight into the state of affairs by simply turning up the hive and dispersing the bees by means of a little smoke.—A DEVONSHIRE BEE-KEEPER.

CANARIES (*P. Carter*).—We conclude from what you state, that either the weather is too cold for your Canaries, or that the other birds do not allow them to feed. We would recommend their being taken out of the aviary and removed to warmer quarters, and that their food be hard-boiled eggs, bread, and canary seed, with occasionally a little hemp, mawseed, and green meat. We presume you supply the birds with plenty of sand in the aviary.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 73.2°, and its night temperature 51.3°. The greatest heat was 92° on the 25th, 1844; and the lowest cold, 38°, on the 21st, 1862. The greatest fall of rain was 1.37 inch.

THE ANÆCTOCHILUSES.

HESE deserve more attention than is bestowed upon them; for well do they merit the title of gems of the vegetable kingdom, from the contrasts in the colour and exquisite markings of their leaves. As exotic Orchids they require at least a stove temperature, in which with proper treatment they thrive well, though there is a general impression that they are very difficult of culture. To this cause alone can I attribute the want of specimens of this genus in almost all stoves; certainly it is not in the prices charged for them that the cause is to be found; and I think that with a greater acquaintance with their real habits, and a certain, and by no means difficult, mode of treatment they may yet be brought into more general cultivation.

Perhaps the only plants under cultivation which have to submit to an unvaried treatment the whole year through, save, it may be, an increase in the minimum temperature during the summer, are those of the genus *Anæctochilus*. Instead of potting these plants as occasion suits, and then placing them under bell-glasses, there to remain an indefinite period, I advise a certain routine of treatment to be observed annually, the heads of which are here given, having myself had proof of the attendant success.

TIME OF POTTING.—All the plants, both large and small, should be fresh potted each spring, as, whether they require pot-room or not, and even when they are apparently doing well, it will at all times, in consequence of the moist state in which they are kept, be well to put fresh and sweet material in the room of that in which they have remained all the winter, and which must have become more or less soured. They will thus be assisted in making a good growth during the summer. The time of potting them must depend entirely upon that at which the house, whether a stove or Orchid-house, in which they are grown begins to receive its summer treatment; at no time would I pot them until a temperature of at least 75° is attained. This, perhaps, would be about the beginning of March.

COMPOST AND MODE OF POTTING.—The material in which I have found them thrive best has been a mixture of two parts of sphagnum, two of silver sand, and one of broken potsherds. The sphagnum, being finely-grown pieces separated from the more minute and dusty remnants, should be well chopped into small pieces; but previously to this, it, as well as the sand, and even the potsherds, should be well washed with clean water. This to some may not appear necessary, but I hold it to be an

essential to success. These materials should be well incorporated together.

I prefer a shallow pan to a pot for growing them, and when possible it should correspond with the size of the plant; or if a specimen-pan is required this should be of the size to which it is desired to grow the specimen, taking care that it match the bell-glass which is to be placed over it. The glass must at all times be kept over the plants. This I prefer to a mode often practised—that of plunging the pan into another, upon which the glass is then placed. The drainage should be abundant, taking care to place a thin layer of sphagnum upon its surface to prevent the sand from passing down.

The compost having been then placed very firmly in a conical form in the pan, the plants should be planted carefully over the surface.

Where the creeping rhizomes have rooted pretty freely they can be firmly embedded in the compost, otherwise a stem without roots should be firmly pegged upon the surface only. Give the whole a liberal watering with a light rose, slightly shaking the heavier drops of moisture from the leaves before the bell-glass is placed over them. A shady warm corner will be the best place for them for a fortnight, taking care if the weather be very bright the first day or two after potting to place over them, in addition to the customary shading, a thin sheet of paper.

PROPAGATION.—The most ready way of propagating them and that generally practised is by division of the creeping stems when of sufficient length, which will be about midsummer; this period, about the middle of their growth, being the best time. The stem may be severed by a sharp knife into as many pieces as will insure to each piece so severed two distinct roots, each having more or less hold of the soil below the surface. The plants so divided should be encouraged by a continuation of the summer treatment recommended below until the following spring.

SUMMER TREATMENT.—When the plants have become more or less established under the bell-glasses after the shift, a frame should be procured sufficiently large to admit the whole without undue crowding. It should be high enough at the back to allow of the pans being elevated upon pots. Three small 60-pots to each will be best, as thus the outer air will be more readily admitted through the apertures at the bottom of the pans amongst the crocks. The air will prove very beneficial to the plants, especially when the roots have struck well down amongst the crocks. No better position could be found for the frame than upon a side stage over the pipes and not too far from the upper glass. The plants will be better of being kept close for a day or two, after which the system of treatment I advocate during the summer, and which seems so beneficial to them, may be commenced.

This consists in taking the glazed light away from the frame about ten o'clock every morning, and giving the whole a moderate watering overhead with clear tepid water; just brush away from the axils of the leaves any heavy drops, leaving them then fully exposed to the

atmosphere of the house until the plants have become thoroughly dry, when the lights should be returned, shut down close, and allowed to remain so until, at the same time next day, the treatment be repeated. Should the surface of the soil be disposed to green over, remove carefully the worst, adding afterwards a slight surfacing.

The *Anæctochiluses* already number upwards of thirty, of which superior as ready-growing are, *intermedius*, *Lowii*, *Lobbi*, *superbus*, *Veitchii*, *striatus*, *argenteus pictus*, *setaceus*, and *setaceus albo-marginatus*.

W. EARLEY, *Digswell.*

INTENDED STRAWBERRY FETE AND BOUQUET EXHIBITION OF THE ROYAL HORTICULTURAL SOCIETY.

THESE were wished to be on the 13th inst., but proved entire failures. There were twenty-five classes with corresponding prizes for Strawberries, but only entries in seven of the classes, and it may be said there was no competition in them, for ten prizes were awarded, and of these Mr. Lydiard, of Batheaston, near Bath, received seven! The heaviest single Strawberry was a British Queen, from Mr. Lydiard, weighing 1 oz. 8 dwt.; the heaviest twelve Myatt's Eleanor, also from Mr. Lydiard, 12½ ozs.

Then it was announced that "arrangements would be made by which it was hoped that Fellows, &c. (and others?) might be able to purchase a supply of the different fruits exhibited;" yet it surpassed belief at the time, when it was announced on the first day, that all the fruit that could be purchased came from Mr. Solomon and Messrs. Webber, the fruiterers in Covent Garden, and that if you bought the fruit you could not have it until the day following! Did not the managers know that freshness is essential to excellence in Strawberries?

The exhibition of bouquet-holders was equally defective. The very beautiful one presented to the Princess of Wales by the Maharajah Dhuleep Singh, was kindly sent for exhibition by Her Royal Highness, and there were eight or ten others in a glass case, but no one knew anything about them, nor did any one seem to care. If prizes had been offered for the most tastefully arranged bouquets, some interest would have been excited, and they would have been more consonant with the objects of a Horticultural Society.

CULTIVATION OF THE MELON.

(Continued from page 23.)

WATERING AFTER THE FRUIT HAS SET.—When the fruit has set and begun to swell water will be needed once or twice a-week, or it may be every other night, so as to keep the soil in a moderately moist condition; and in addition to this a watering, which should be given about two o'clock in the afternoon in April, or if earlier in the season in the morning, and after April at the time of shutting up the frame, let that be when it may, so that the plants may not only feel the refreshing influence of water at the root, but that of a moist atmosphere, such as is produced naturally after a shower. They should be lightly sprinkled overhead daily at the time of shutting up the frame on the afternoons of hot days, to create a moist atmosphere, presently to be cooled down by the cold of night, thereby producing a kind of artificial dew to repair the waste in the day, and reinvigorate the plants. This sprinkling overhead should not be practised in dull, cloudy, or rainy weather, nor should the watering be then so plentiful; but at the same time it is necessary to have the soil in a moist state whilst the fruit is swelling; three gallons of water at the same temperature as the frame being sufficient to apply to one light at a time. Whenever water is given, or the plants sprinkled overhead, care should be taken not to wet the stem or centre of the plant whence the branches radiate, or the stems will very soon decay at that part. The soil beneath the centre of each light should be slightly elevated above the rest of the surface, so that water may be carried away from the stems of the plants, and a space a foot in diameter, which is supposed to contain the stems of the plants, in the centre of each light, should never be wetted more than can be helped after the bed is earthed.

When the fruit begins to net water must be supplied rather less copiously, still keeping up a moderate moisture in the bed and atmosphere; but when the netting spreads to nearly every part of the fruit, cease syringing or sprinkling the plants overhead, and diminish the supply at the root to one-half what it was when the fruit was swelling. After the fruit has become netted all over desist altogether from watering the surface of the soil, and unless the foliage begins to show signs of want of water, no more should be given until the fruit is ripe; but if water be absolutely necessary to keep the foliage in good order, it must be given by making holes in the soil and pouring water into them through drain-pipes, for a dry atmosphere is essential to the perfection of the fruit. The soil even when the fruit is ripening should be in such a state of moisture as to cause the fruit to ripen fully. Watery and insipid fruit is the result of a moist atmosphere; but dryness induces richness of flavour, yet too dry a soil affects the juiciness of the fruit. Too much moisture in the atmosphere, also, at the time of ripening, with a wet soil, causes the fruit to crack, especially if accompanied by a low temperature. The soil, therefore, should only be kept moderately moist after the fruit begins to net, and the atmosphere cannot be kept too dry if fruit is desired and needs no sugar to make it fit to eat.

TRAINING.—It is presumed that the plants were stopped prior to planting out, and supposing them to be stopped at the second rough leaf, they will each push three or four shoots, one from each of the rough leaves, and generally one from each of the bases of the seed-leaves, and these shoots do not spread much before they push laterals. These laterals, if left, overcrowd the neck of the plant; but as we are not certain that the shoots on which we are depending to produce fruit will do so, it is advisable to retain two or three laterals on the two shoots that spring from the base of the plant, and such laterals should be stopped at the second leaf. The first and third lateral of every alternate principal shoot should be cut away close to the shoot from which it takes its rise, the intermediate shoots having the first and third laterals retained, the second only being cut away. The laterals retained to supply the place of the principal shoots should these not set their fruit, or in order to supply shoots for a second crop, should be stopped at the second leaf, so as to throw as much support as possible into the principal shoots. These will grow rapidly and continue to throw out laterals as they advance, each of which must be stopped at the second leaf, and this stopping will again cause the sap to flow freely into the principal shoots. These should be trained at equal distances apart towards the front or back of the frame, according to their position; the distance between them should be 1 foot. We have now only to cut clean out every alternate lateral for 1 foot from the lateral left at the base of each principal shoot, stopping those left at the second leaf unless fruit be shown, when they must be stopped at the joint above the fruit, but not until the flower has been properly impregnated and the corolla has closed. By the time these laterals push sub-laterals the principal shoots will be advanced to within 6 inches of the sides of the frame, when we stop them. This will induce laterals, and on these and the laterals already stopped, now pushing sub-laterals, we expect fruit will be shown in sufficient numbers to warrant our keeping the atmosphere dry for a time, to facilitate the setting.

The proper number of fruit on a plant is two at an early period of the season, or later on when large fruit are required; three after April, to afford full-sized fruit, and as many more as desired, only no one need expect to have on one plant six Melons equal in size to those on plants producing two or three. It not unfrequently occurs that the laterals retained near the stem of the plant show fruit, in consequence of the frequent stopping, before those on the principal shoots do so. Some make a practice of taking such fruits away, the reason being that if they should set they will require moisture for swelling, and that if not supplied with it they never attain any size, whilst if moisture is supplied on their account it endangers the principal show of fruit. Though it is preferable to have the flowers open at nearly the same time, yet I do not consider it wise to miss a couple of fruit on a plant, though it be the only one in a frame that shows so early, for fruit formed early near the

stem invariably swell the best, and are the most handsome. It should, however, be borne in mind, that it is very undesirable to treat such fruit as if the principal crop were to be subordinate to them. Many cultivators of the Melon, however, consider that an early fruit, or one in advance of the rest, prevents others from setting freely, if at all; or if these do, they seldom attain the perfection they would were there no fruit in advance of them. This opinion I must say is also in accordance with my own experience, but I never could resist the temptation to get fruit set as early as possible; and from plants in different stages in the same frame, I have had fruit insipid in one case, and excellent in the other. It is desirable, therefore, to have the fruit set as nearly at the same time as possible, and though we have provided for this, it may happen that the plants do not show fruit so freely as we could wish, or if they do they do not set. I have said before, and I now repeat it, that the bottom heat should be brisk (80° to 85°), and a dry atmosphere with a change of air daily must accompany the setting. With these conditions secured, the soil moist and firm, the plants not far from the glass, and strong, short-jointed wood, there is no difficulty in the matter. After the fruit is set provide a piece of blue slate or tile, and on this stand the fruit, which will prevent the side next the earth rotting, and to a great extent its not ripening on that side. I have tried glass, &c., for keeping the fruit from the damp soil, but have found nothing equal to pieces of common roofing slate.

PRUNING.—Pruning the Melon after the fruit is set is confined to stopping all growths as fast as they appear to two leaves, so as to throw as much support as possible into the fruit, which will swell rapidly, and in order to insure its doing so, all the leaves should be retained, except such as are yellow. After the fruit begins to net, a few of the small shoots should be cut in closely so as to admit more light and air to the fruit; but do not remove the large leaves, for on them depend the size and quality of the fruit. After the fruit is set and swelling all pruning, therefore, should be limited to thinning-out the useless wiry shoots that spring from the principal shoots or laterals, and to keeping those left above the fruit stopped at every second leaf, so that neither the wiry shoots nor those above the fruit may rob the principal leaves of their due share of light, air, and nourishment. Some make a practice of cutting away most of the laterals after the fruit is set, but retain a growing point above the fruit, and it is stopped repeatedly at every two or three eyes. This is a first-rate system if the principal leaves can be preserved in a healthy state until the fruit is ripe, and when no second crop is desired from the plants; but should the leaves be scorched or attacked with red spider or thrips, the fruit does not attain that perfection it would were there leaves in a healthy state to elaborate the food absorbed.

When the fruit approaches maturity the greater part of the laterals and leaves, with the spray-like shoots above the fruit, should be removed, retaining, however, any healthy large leaves that may be on the main shoots for a short distance each way above and below the fruit. These will be sufficient to attract and elaborate the food necessary for the maturation of the fruit, whilst the removal of the spray-like shoots with their small leaves will admit more sun heat and air, and materially improve the flavour, giving a richness that renders sugar unnecessary. The fruit may now be elevated on an inverted flower-pot, still keeping the slate beneath it, for if it be placed on the pot without the slate, the steam of the bed or moisture rises and keeps the under side of the fruit wet, and may cause decay there. This raising the fruit nearer the sun completes the ripening, and heightens the aroma.

RENEWING GROWTH.—Should the plants appear disposed to grow vigorously after the laterals are removed, and a second crop be desired, choose four or five of those that are near the stem of the plant. Give no water, however, except enough to keep the plants alive, and in a rather healthy state. Trim away all other laterals except those bearing fruit, which will cause those left to take the extra sap, whilst the small quantity now needed for the support of the fruit will not deteriorate the quality in the least; but should extra support now be thrown into the fruit it not only injuriously affects the flavour, but is a direct cause of cracking. The fruit being ripe the old vines or principal shoots are cut

back, the bed watered, and the shoots retained for a second crop treated in the same manner as those for the first crop. It is of little use attempting to obtain a second crop unless the fruit is ripe in July, or sooner, so that a good plant can be preserved, and the fruit can be set in August.

ANOTHER MODE OF TRAINING.—The most simple and most generally-adopted system of training Melons in dung-beds is to stop the plants at the second rough leaf, and then allow them to grow for a fortnight or so after planting-out, by which time they will be well furnished with shoots. Four or five of the strongest shoots are then selected, and spread out at equal distances, with their extremities pointing towards the sides of the frame, care being taken not to cross the shoots of one plant with those of its neighbour, one plant being taken to the back, the other to the front of the bed. Then cut clean out the spray shoots that cluster round the stem, which should at all times be kept free both of these and leaves, as they prevent the circulation of a due amount of air, and cause weakness, canker, or gummy exudation at that part of the plant, resulting in the death of the plants before the fruit attains maturity. The shoots are encouraged by taking away the small worthless shoots near the stem, and are trained from 9 inches to a foot apart. When they reach to within 6 inches of the sides of the frame their points are pinched off at a leaf. This causes the production of side shoots or laterals, and on these blooms appear nearly simultaneously throughout the frame. The atmosphere is kept dry, the flowers are duly impregnated, and by these means, with a brisk bottom heat, the setting of the fruit generally takes place. When that is effected a piece of slate is placed under each fruit, the shoots are kept rather thin by cutting out the weakest, and stopping the strongest, so as to cause support to pass into the fruit, and a good root-action kept up by the formation of new growths. The shoots are repeatedly stopped and thinned after this, so that the principal leaves may not be prevented from duly performing their functions for want of light and air, nor robbed of support by a quantity of useless small shoots. This is all the training given in many cases, and I can vouch for large and fine-flavoured fruit being obtained in this way.—G. ABBEY.

(To be continued.)

MY ORCHARD-HOUSE.—No. 5.

“EHEU FUGACES!” How swiftly fly the precious moments! Let us employ them well. It seems but yesterday that I saw my Peach trees in bloom under a canopy of snow, so thick and heavy overhead as to make it seem twilight instead of a February morning. Conspicuous among them was the Honey Peach, with its lovely rosy blossoms, so unique that any one could recognise the variety at a glance. And already we are gathering the fruit! Ever since the beginning of the month we have had fine ripe Early York Peaches, generally 8 inches round, and well coloured. This is what the orchard-house does for us—it hastens the ripening, and secures us a certain crop; it also enables us to grow delicate varieties of Peaches and Nectarines, which would never thrive out of doors. But to my mind, its great value lies in the succession of ripe fruit which can be obtained by a little skill.

It is worse than useless to grow Peaches for a six-weeks season. In favourable seasons many are wasted, and this noble fruit degenerates in value from its very abundance, while in cold and wet seasons there are not only very few, but these do not last. Now, in the orchard-house there is no need to dread these results. Unless, as it is facetiously said, there are none produced at all, there is no reason why we should not have a three-months Peach-season, not to speak of Plums, Cherries, Apricots, &c. Three months constitute a large portion of the whole year, and if we can secure any particularly valuable fruit for this length of time it is saying a great deal in its favour. Orchard-houses do this—first, by ripening fruits early in themselves, and by making them earlier still; then by hastening midseason varieties, so that the same kinds on the wall shall come in directly afterwards; and lastly, by producing late fruits such as the open wall cannot be expected to ripen at all. This has been our regular practice, and from July to November it is easy for our numerous visitors to judge for

themselves. A large portion of the fruit is sent to Covent Garden Market, though the house is not organised for the sale of the produce by eliminating valuable but not prolific sorts, and it is really painful to see the gorgeous varieties sent to an indiscriminating public, and to rapacious dealers. What would these care for tropical Peaches—rare sorts imported by Mr. Rivers, and carefully selected and sent to me as a favour by him? The public has much to learn still about the trouble these things cost the producer. Judging from the average knowledge of our visitors, I should say about one-third do not know a Nectarine from a Peach when they see it. We find, too, that many who themselves cannot grow even common things, are much disappointed unless the orchard-house is literally breaking down with the weight of early Peaches. As if anything early is ever remarkably fine or prolific! There is undoubtedly great ignorance about these matters—not that we know much more ourselves as yet, but orchard-houses are excellent instructors; even for that reason they should be built.

One thing orchard-houses do teach, and that is not to overwork the trees. I believe that the poor things, if called upon for the credit of the house, would risk any amount of vegetable vitality. I once put it to a favourite diagonal cordon to show visitors what we could do working sympathetically together. I was to prune scientifically, to water carefully, and to feed it well; besides, abundance of light and air was to be provided for it. It then engaged to do its best, and being young had no thought about consequences. The result was one hundred and twenty fine Early Newington Nectarines, but the poor diagonal has never been quite well since. It occupied about 30 square feet of the back wall, making thus four Nectarines per square foot.

To prove what I advanced before—that orchard-houses have the valuable quality of hastening the period of ripening fruits as years advance—Early York, ripe August the 1st in 1861, was ripe on the 23rd of July in 1862, while this year it is as early as July 4th. Canary, ripe July 23rd in 1862, was ripe on July 20th, 1863, and July 11th, 1864.

As to produce. This year we have 1200 fine fruit, Peaches and Nectarines; about 100 Apricots, and a fine promise of Figs; a few Plums, no Cherries, having no room to spare; but I see them growing well in my friend's houses. We have also, along the rafters, about 100 bunches of Grapes. All this produce is first-rate in quality, and would be much greater but for the variety of trees growing, many of which, though good, are not prolific. These are retained for the sake of experiment, but will ultimately be condemned.

The weather has again changed, and become warm, and there is much lack of moisture. Our tanks are sadly tried, and I have no doubt that watering is a sad toil to many just now. Syringing is freely kept up; and we always syringe, even when the fruit is colouring. The practice is condemned by some; but I must confess that the reasons given do not seem very sound. At night, especially, how does syringing affect the flavour of fruit more than a heavy dew?

As to ventilation, it seems in July and August as if no amount of openings can be sufficient. The atmosphere is at times inconveniently close and unwholesome, do what we will. This must affect the vitality of the trees, especially if at all crowded. At any rate we find that the red spider abounds, and does most injury in trees placed in corners, where the draught does not affect them. In the same way, branches and shoots in dusty or neglected places are sure to become a prey to insects.

The shoots on the Peach trees have now elongated considerably, and, if destined to prolong the branch, have even required to be stopped freely. It is well not to do this too early in the season, unless the tree is bare at the lower portions. By allowing them to extend and strengthen first, the tree will much benefit in general vigour. As to those destined to be fruit-bearers, we have already discussed three classes of them. There remain now only two more classes, and these I shall briefly notice. The first of these two is a shoot composed in nearly equal proportions of fruit-buds and of wood-buds, the latter, of course, nearest the stem. If out of doors, in the winter cut above the second triple bud; but if in the orchard-house, at the summer pruning pinch in to four well-coloured leaves at the first pinching-in.

The other class are very vigorous and long, composed

chiefly of wood-buds, perhaps a few fruit-buds near the summit or point of the shoot. Out of doors, in winter, cut in to two buds close to the stem, to produce two new shoots next season. In-doors, if you recognise these shoots clearly, and do not require them to fill up, then pinch back very short—to two leaves. At any rate, be much on your guard against these shoots; they are not useful, nor productive, and may become very gross and rampant, absorbing sap and doing no good with it. Should the close summer pruning be early, by having discerned their nature in time you will probably obtain two weaker shoots from the two eyes left, and these may ripen too, and bear. However, by pinching in to four well-coloured leaves when the summer shoot has had time to be sturdy, and not before, and then to two leaves the second growths, as soon as these are pretty sturdy, the third growths may be pinched in closely any way. The leading branches to be allowed to gather strength before stopping them also. This is the easy science of in-door Peach-pruning. Summer laterals (*anticipes* in French), to be pinched in just above the first pair of leaves. But these also should be allowed to make a little growth, or they may shrivel up. This is the chief secret—close summer pruning in, but not too early in, the season.—T. COLLINGS BRÉHAUT, *Richmond House, Guernsey.*

NOTES FROM PARIS, 1864.

ROSE LORE.

To me there is no greater treat connected with a trip to Paris than a few hours' chat with my good friend M. Margottin, of Bourg-la-Reine. I am always sure to get information, and reliable information too, on many points connected with the Rose. And then he is such a thorough enthusiast—and one does like an enthusiast, for it implies earnestness—and the Rose has been so especially his flower, he has given so much time and thought to it, that he is not a mere Rose-grower or Rose-seller, but also a Rose-lover. He will discard Roses which some other growers would send out with high-sounding names and descriptions; and hence there have been comparatively few Roses sent out from his establishment which we can well do without, while Jules Margottin and Louise Odier will be grown as long as Roses are grown. Some people say he is bigotted in his opinions. I dare say he is, and he has a right to be; for if a man knows a subject thoroughly, if he has grasped it in all its proportions, he must be necessarily in the eyes of others, when he maintains views and opinions which he knows to be right, considered as such. In a very old book I find it written of one, "Unstable as water he shall not excel," and so with those who are readily moved by what this or that person says; but I am bound to say I find a good deal of good honest common sense in all he says, and were he on our side of the channel I should call him a thorough John Bull.

We had, then, on that bright sunny day after the thunder-storm of the 9th, which had so much damaged his bloom, a good chat as we went amongst his fine stock of standard plants. The hybridising of Roses came up on my asking him his opinion of John Hopper, which he pronounced a grand Rose, and telling him he had something to say to it, as it was a child of Jules Margottin; he then stated what I was before unaware of—that he, at any rate, of the French nurserymen, does not trust to the chance hybridising of insects, but that he has for years regularly crossed some of his flowers. At the same time he does not seem very much enamoured with the results, and thinks he has perhaps done as well where he has not done so. He found, as most have done, that strange freaks are played in this matter. As my friend Mr. Standish has found that from two white Grapes he has produced the very blackest Grape he knows, so from two red Bourbons he had obtained a fine white, of which he had entertained great hopes. He had grown it for several years, and he then determined on propagating it for sale. But alas! it would not then open well, and so he discarded it; for, as he justly observed, a Rose that will not open well in France is sure not to open well in England. The Bourbon Rose which he sent out this season named Reverend H. Dombrain, was a seedling from Louise Odier crossed with Général Jacqueminot; and as I saw it there it

combined the qualities of both parents, the shape of Louise Odier and the colour and perfume of the Général. Then, again, his seedling Duchesse de Montpensier, raised by him in 1845 and sent out in 1847, was a seedling from Madame Laffay and Mrs. Bosanquet. Duc de Cambridge, again, was a seedling of Madame Fremion raised by him in 1850; while Jules Margottin, probably the best and most useful Rose he has ever produced, was a chance seedling, and the plant did not bloom for six years. From this Rose he has a seedling to be let out this year, very bright and clear in colour, and of large size. He had, he tells me, crossed Persian Yellow with a rose-coloured Hybrid Perpetual, and obtained a pure white Rose; but this never opened, and all his efforts in this direction had been frustrated.

The immense number of red, scarlet, and crimson Roses annually sent into the market, and their great similarity one to the other, was also commented upon. In excuse of the French raisers, he said that there being no such competition as in England, raisers knew very little of what they each were doing. One man at Lyons, another at Caen, another at Abbeville, another at Angers, raise a very fine Rose. It is good—seems to them, at least, magnificent; and hence it is “put into commerce.” All come over here; and when they bloom with us, alas! it is the old story of tweedledum and tweedledee. In truth, he says, ever since the introduction of Général Jacqueminot the rise has been all in that direction; and he has now determined to, in sporting phrase, “try back.” He has a number of Roses planted under sashes, and these of varieties which were sent out before Général Jacqueminot, and he hopes from these to obtain something novel. When I was there the pips were already well swollen; so that, doubtless, with a fine summer he will secure a good crop of seed. Concerning the Général, he told me that it was obtained by a M. Roussel, at Méredon near Paris, who had for thirty years been seedling from Gloire de Rosomène, convinced that some day or other he should obtain something good from it. When on his deathbed, he told his gardener (Rouselet) that he had not much to leave him, but he would give him all his seedlings, and that if he managed well he would soon make his fortune. That very year Jacqueminot bloomed, though its raiser never saw it, and in 1853 was let out; but Master Rouselet was too fond of his glass and did not make his fortune. Géant des Batailles was raised, I believe, near Lyons, by an amateur of the name of Nérard, who in the same way for many years had been saving seed, convinced that he would obtain something good. It was sold to Guillot and by him let out. Margottin said he had not been any more successful than others in striving to introduce other blood amongst the present race of Roses. He had tried to hybridise with the microphylla Rose, but never could get anything worth keeping.

Concerning some of the newer Roses, also, we had some interesting conversation. I do not at all find him disinclined to acknowledge the merits of the flowers of other raisers. He pronounced François Lacharme and Charles Lefebvre to be the best two Roses in their class. Monte Christo comes sometimes very fine; but those Roses described by French raisers as nearly full are very disappointing. You imagine you are going to have a fine bloom; it looks beautiful, colour excellent, but it has hardly expanded before the eye shows itself. This is the case with Peter Lawson, Vicomte Vigier, Mlle. Julie Daran, and many others—splendid when you can catch them in the bud, but very soon disappointing your hopes and expectations. Beauté Française he pronounced to be too like Léon des Combats, as I have myself since proved it to be in my own garden. John Hopper, as already said, he pronounced to be a first-rate and distinct Rose. Baron de Rothschild he also thought, as we have found it here, excellent, and Le Rhône also.

With regard to new Roses, M. Eugène Verdier purposes sending out six this season. Of these the finest are Rev. F. Radcliffe, named in compliment to the Vicar of Euston—a Rose of the Madame Victor Verdier class, but very bright and clear in colour; and Maréchal Niel, a very fine Tea Rose, said to be a seedling of Lamarque, very vigorous, free-flowering, and clear in colour. It is not absolutely new, as it was raised somewhere in the provinces, but is very little known. His other Roses were only under figures, and therefore to say aught of them now would be of little

use. M. Charles Verdier has two of his own raising of which he speaks highly; while Levèque has at present one. Margottin has one, certainly not yet named; and another, a white, of the shape of Madame Rivers, but pure white. Of this he is not certain, and waits to see how it is this year before offering it for sale. Marest is also said to have one. This is all I could hear or see of Paris Roses. Mr. George Paul, who had the kindness to find me out in Paris, went further south—to Brie, Fontainebleau, and Lyons, and has doubtless notes of what he saw. I am inclined to think that French raisers generally are awakening to a sense of what they have put on English growers; and I am hopeful there will be more caution in selling, while I am quite persuaded there will be more caution on this side in buying.

And now adieu to Roses, and flower shows, and gardens for a while. Ere this is in print I shall be off to the wilds of the far west of Ireland, engaged in other work than this, and in revisiting the scenes where many a happy day was passed—feeling, I dare say, how like a dream life is, and how impossible it is to conjure up the feelings of past days even in the midst of those scenes.—D., *Deal*.

A PANELLED LAWN.

A FEW days since I saw a beautiful variegated, or, rather, almost white, grass, suitable for lawns. I think that a lawn planted with such grass, or worked into panels or ribands with green grass, would have a very fine effect. Has the plan been tried anywhere?—JNO. CLAYTON.

[Is the grass a dwarf variety of the Gardener's Garter (*Phalaris*)? Whether or not, we do not think it would be effective ribanded with other grass alone; but it might make a good edging to flower-beds, with the grass lawn round. We should like to see a piece of the grass, and then we should be better able to give an opinion.]

BLACK PRINCE GRAPES.

ALLOW me to correct an error you have allowed to creep in with regard to the weight of our Black Prince Grapes, page 26 last week's JOURNAL OF HORTICULTURE. Your weights of the four dishes in the previous week's Journal were perfectly correct, page 5. The weight of the heaviest dish was 13 lbs. 10 ozs. The centre bunch weighed 5 lbs. 7 ozs. The heaviest dish previous to this was shown June 24th, 1863, at the Royal Botanic: the three bunches weighed 9 lbs. 5 ozs.

The whole of the Black Prince Grapes exhibited from here for the last four years are from grafts on the Frankenthal, not Mill Hill as mentioned this week. The first dish was exhibited on the 5th and 6th of June, 1861, on the opening of the Royal Horticultural Garden, and weighed 8 lbs. 14 ozs. I find the Frankenthal the best of all stocks for grafting, and the Barbarossa the worst.—W. HILL.

[We shall be glad if our readers will furnish us with the heaviest weights of Black Prince they have met with.]

PEACHES UNDER GLASS AT BRADFORD.

THERE has been much said about growing Peaches, &c., between Mr. Abbey and some others of your readers, and a slur was cast upon all the gardeners about Bradford and its neighbourhood. I have been in my present situation nearly twenty years, and I have grown good crops of both Peaches and Grapes. If you look in THE COTTAGE GARDENER for December 23rd, 1852, you will find an article by Mr. W. Dobson, entitled “Grape Forcing, good specimens of.”

Our place is as black as possible; for, about half a mile north of it, there are some chemical works; three hundred yards to the north-west there is a brickyard; and I have had to close the houses at midday when a kiln of bricks has been burning, or else the sulphur would have destroyed all in the houses. Then, from west by south to east, lies Leeds, a town, I should think, as black as any in England—nothing like it in Herts. The houses are all close to the garden wall, and, except on the north-west, it is as black as anything you can conceive.

I send you a specimen of Peaches grown in the gardens of J. O. March, Esq., and I have had a good crop for the last fifteen years, except one season. The largest Peach was 12½ inches round, of the Royal George variety, the same as I send. The tree has no grand south border to grow in, but the roots are under a path 4 feet wide. The sun shines on it about three hours in a day. There are Vines in the house as well.

If we poor soot-persecuted gardeners grow fruit like that I send, what ought our more favourably-placed brethren to grow, with their pure air and fine soil—for ours is nearly clay—with good leaf earth? Nothing will grow in our leaf mould; it seems to poison everything.—J. ACOMB.

[The Peach sent was a very fine specimen 10½ inches in circumference, weighed fully 9 ozs., was highly coloured on the most exposed side, fully ripe, and of good flavour.]

WHITE HELLEBORE VERSUS GOOSEBERRY CATERPILLARS—BIRDS.

It is all very well for your Yorkshire correspondent to talk of his Gooseberry trees being free from caterpillars, and to give the credit to the birds. Birds abound in my garden, and caterpillars would abound too unless means were taken to prevent it. There is an easy cure for the Gooseberry caterpillar, and a certain cure if it be only rightly used, and that is hellebore powder. Some will tell you that hellebore does no good, and no wonder when it is used in the manner many do. They let their trees get half covered with the caterpillar, then sprinkle them with the hellebore, and think they have done what is necessary. They might just as well do nothing. The right plan is for a man to keep his eyes open, and so soon as he sees the very first signs of the caterpillar to dust all the trees with hellebore, and to repeat the dose in two or three days. Let this be done when the caterpillar first shows itself, and success is certain. But I repeat that all depends upon the remedy being applied in time. Many, very many, gardeners spoil their work in this and other things for want of being soon enough. They are constantly too late, and you will see them locking the stable door long after the horse has been stolen.

And now for a word about "the birds." They are very pretty to look at, and it is very pleasant to hear them sing; but, notwithstanding, I would rather have their room than their company. I am told they do much good. It may be so, but I am sure they do a great deal of harm. While the good in my judgment is problematical, the mischief is manifest. In the matter of fruit, birds are the greatest possible nuisance. It is impossible to keep any fruit from them without nets, and not seldom they will have it in spite of nets. It is fortunate that orchard-houses help us here as well as in other points. I am glad to say that my orchard-houses are again full of fruit this year, as they have been for the last eight years, notwithstanding that I live so far north as

—NORTH LANCASHIRE.

FUZE VERSUS GOOSEBERRY CATERPILLARS.

As regards the placing of Furze in a bush for the destruction of the caterpillars, I can say that I tried it in one bush which was much infested, and in a few days they had all disappeared, nor have I seen any one since on that bush, though plenty have made their appearance in other parts of my garden.—A. H. F.

GARLIC VERSUS GOOSEBERRY CATERPILLARS.

HAVING noticed the discussion as to the prevention of the caterpillar by Furze, I think it may be interesting to some of your readers to know, that I was looking over a gentleman's garden in the neighbourhood a few weeks ago, and observing some roots of Garlic planted round the Gooseberry bushes, I asked the gardener what they were planted there for, and he replied, "To keep the caterpillars away," and he assured me it was quite effectual. This remedy may be worthy of a more extended trial, for Garlic is more useful than Furze in a kitchen garden, and it may as well be planted round the Gooseberry bushes as anywhere else.

Can you inform me if there has been published at any

time any alphabetical list of flowers with the different composts proper for them? Such a list on card in the form of a chart to hang up in the potting-shed would, I think, be useful to many amateurs, at least, I know it would be so to me and to all beginners. I have often thought of preparing such a list for myself, but could never find the time.—E. B. B.

[We know of no such list. A gardener would not require it, and an amateur would consult our "Garden Manual," or some other work if he had any doubt as to the formation of the compost.]

TAN VERSUS GOOSEBERRY CATERPILLARS.

My Gooseberry bushes were much damaged by caterpillars last year; and as I read in your paper that the best remedy was to place a circle of tan about 2 inches deep under each tree, I have this season tried it with perfect success to the present time; and as the Gooseberry bushes in the garden adjoining mine are this year, although not, perhaps, so much as last, attacked by the same pests, I am glad to make known what I believe is a simple as well as effectual remedy for this evil.—H. M. GAMMON, Oxford.

BROOM VERSUS CATERPILLARS.

If your readers will, as I have done for many years with perfect success, twist a good wisp of fresh Broom round the stem of each Gooseberry bush, so that no vermin can creep up from the earth except through the Broom, and see that it is properly twisted round and not a mere show, and that it is done just before the leaf-buds begin to open, so as to be fresh and bitter to its crawling friends, they never will be troubled with caterpillars.—J. MACKENZIE, M.D.

FAILURE OF SELAGINELLA DENTICULATA. EDGINGS FOR CONSERVATORY FLOWER-STANDS.

In an open colonnade here we have three semicircular stands exactly like those in the conservatory at Kensington. This is the second year we have had them, and as yet we have not been able to make the Lycopod (*Selaginella denticulata*) answer well for the edging. Do you think the following mode of treating it ought to insure success?

In March of this year I filled the wire baskets nearly to the top with good turf loam chopped fine. I then spread the Lycopod all over the surface, and covered it thinly with finer soil, and placed the baskets under the stage in the greenhouse, where they remained until the end of June, when they were placed round the stands. The Lycopod seemed to be going on nicely up to that time, but since then it has begun to look worse. My opinion is, that the cause of failure may be attributed to the fact, that from the time the sun reaches the meridian until the time of setting, it shines full upon the stands. My employers have an idea that Mignonette would answer better than the Lycopod.—BOLNORE.

[The full exposure to the sun of the stands in the open colonnade is the reason why your *Selaginella denticulata* will not answer round the edges. It must have partial shade as well as moisture. Instead of Mignonette for such edgings, we would recommend a fringe of drooping *Anagallis*, or of *Verbena pulchella*. If the sides of the stands are of a white colour, dull them to a dark colour. After the creepers are all over it, the colour will be of less consequence.]

SALVIA ARGENTEA.

AMONG the many plants which are cultivated for the singularity of their foliage this is by no means the least remarkable. With a leaf as large as that of a Cabbage when fit to transplant, and of a thick and woolly texture, its appearance amongst other plants is singularly beautiful. In point of whiteness it is not equal to *Centaurea candidissima*, nor even *Cineraria maritima*, but it is possible by planting it in suitable soil that it may be improved in that respect; but in its dwarf sturdy habit, and thick blanket-like foliage, clothed with a long hairy down, it possesses features widely distinct from anything else that I am acquainted

with. It also possesses the merit of being of easy growth, and adapting itself to all situations. Although not an annual, it is most readily propagated by seeds, which are to be had of most seedsmen; and if sown early in spring the plants may ornament the parterre during the same summer, and a few plants retained in pots will look well all the winter when such plants are far from plentiful. In the following spring, most likely, it will run up to flower, though the plant is not improved by its doing so. The flower, which

is white, is by no means unsightly; in fact, it is prettier than one that came out some years ago as a great acquisition—namely, *Salvia patens alba*, for the flowers of *S. arvensis* are individually larger than the other, and in colour and form equally good. I have never used it for bedding purposes, but for mixed borders a few plants introduced amongst other things give an aspect different from anything else I am acquainted with. *Stachys lanata* affording the nearest approach to it.—J. ROBSON.

HINTS ON ICE-HOUSES AND ICE-HEAPS, &c.

[HAVING recently had applications from some of our readers for No. 588, containing hints by Mr. Fish on the above subject, and that Number being out of print, we reproduce the greater portion of his article, with a few additional notes.]

ICE-HOUSES are generally made in the shape of an inverted cone, or an egg with the largest end uppermost, and a medium-sized house might be 8 feet in diameter at bottom, 11 feet at the widest part, and 14 or 15 feet deep from the bottom to the top. When bricks are used there is no difficulty in thus having it round; but I have no prejudice at all in favour of such a round house; but for all purposes would as soon have a square building, whether built of stone or wood, or any other material.

Fig. 1 is a section of the egg-shaped well as commonly

built, with a trap drain from its bottom, and the bottom covered over with logs of wood and rough brushwood for a depth of a foot or 18 inches. It is furnished with a passage and a door outside and inside, so that the space between them may be filled with straw. As will presently be seen, we prefer a double wall instead of a single one, with an open space between of from 9 to 12 inches. The opening shown at the top is of great importance for filling the well, where the position of the ground will admit of it. If a layer of clay can be rammed against the outer wall it will be an improvement. The ground around the well should be shaded with trees and evergreens.

Fig. 2 is a section of one of the simplest and best ice-houses I have met with. As far as I recollect, it was built square, with stone walls, 16 inches thick, enclosing a square

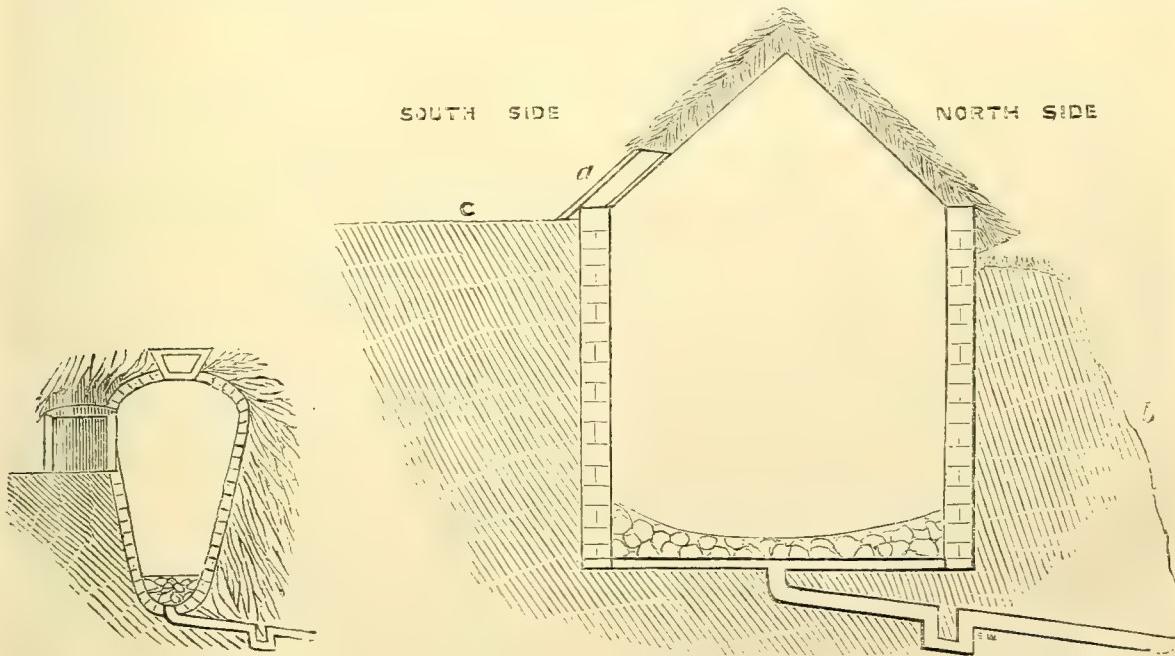

Fig. 1.

a, Double doors.

Fig. 2.
b, Steep bank.
c, Surface line.

of 16 feet by 18 feet deep. One side abutted on the level of a field, and the opposite one on a deep sloping bank, the base of which was below the bottom of the ice-well. The ground being light the drain was of little use, as the moisture escaped at the bottom. The ice was carted along the level meadow to a platform at the doorway. There were two doors; the outside one was of stout deal, on hinges which enabled it to fold back on the roof. The corner one fitted loosely in a groove, and this door was lined with woollen cloth. Though these doors were on the south side of the roof, the ice never failed. The roof was formed of 12 inches of thatch, and then fully a foot of close heath or ling. The ice was pretty well beaten outside, pitched in at the doorway, and then pounded down inside. Nothing as a house could be more simple, or keep ice better; and the ice being

taken from clean water, venison, game, &c., were kept in the house for long periods untainted.

In most of the old-fashioned egg-shaped houses there is a long passage leading to the well, with two or three doors, and, in many cases, the ice must be all carried in and out through that passage. With two padded doors, and a space of 15 inches between them, the long passage may generally be dispensed with; and, although the ice should be removed through these doors, it will always be an advantage to have an opening at the top for throwing the well-broken ice into the well. I have known several cases of severe illness as the result of men being kept for several hours in these long passages shovelling the broken ice past them.

Where dryness may be secured there need be no objection

to sinking the well wholly below the ground. In soils retentive of moisture care should be taken to prevent the outside moisture penetrating through the walls, by building them in cement, ramming clay round the wall, with tar next the wall, or raising them partly, or nearly wholly, out of the ground. It is quite a mistake to suppose that to keep ice well you have merely to get it into a hole beneath the surface of the ground. On an average the earth will be warmer all the year round at the depth of the bottom of the well than at the surface. All moisture getting to the wall would melt the ice; the moisture that would ooze out from a wall above the ground would actually cool the interior by evaporation.

I have not had any ice-houses entirely above ground under my own charge; but I have noticed how well the ice kept in several, though, as far as I recollect, half as large again as the size mentioned above. I remember one house above ground that was built with double brick walls, the walls being separated 12 inches from each other, with a door in each wall opposite each other, about 5 feet from the ground level. The top of the house, steep and cone-shaped, was thatched to the thickness of 18 inches, and extended beyond the walls for a couple of feet. The outside thatch got covered with mosses and lichens, and there was a dense shade of trees over all. A temporary staircase led up to the doorway, and a stone staircase inside led to the bottom of the house. The ice was pitched in from the carts, and broken inside, and it kept remarkably well. The great secrets in this case were the double walls and the enclosed space for air between them. Of all non-conductors of heat, enclosed isolated air is the best. Neither what we call heat, nor what we call cold, has the power, to any great degree, to pass through it. I recollect once noticing in the end of June the thermometer in the shade, against the outer wall of such a house, indicating 77°, and another thermometer on the wall inside the ice-well ranging from 32° to 34°, but we shut the doors behind us.

In sunk wells this double wall is just of equal importance. The outer one prevents the heat of the soil affecting the ice. I met with a nice example of this some time ago. An old-fashioned ice-well had been so built, and answered remarkably well. In course of time three or four ice-tubs had to be supplied at the mansion instead of one—everything in summer had to be cooled with ice—and the supply, from the house being opened so often, was not equal to the demand. The supposed genius of the establishment counselled the removal of the inner wall, which would at once make the house about 3 feet wider from top to bottom, and set at liberty so many thousand bricks for other purposes. What could seem more feasible? and accordingly it was done, and the house well filled the next winter; but the enlarged house was emptied fully six weeks earlier than it used to be before. Since then the waggon-loads of straw packed against the walls inside, and the trouble, would soon cost more than the double wall, and, after all, with far inferior results. Few things are better non-conductors than straw, especially if not much bruised by the flail or threshing-machine, as every space between the joints is, so far, a sealed-up air-tube; but let that straw get thoroughly soaked inside a house, and its non-conducting powers would not only be gone, but the vapour always rising from it would keep a damp fog always resting upon and melting away the ice. I have no faith, therefore, in straw as a non-conductor inside a house unless it be kept dry. I have a large house which, when filled, generally secures pretty well a two-years supply; that, too, had been built, I believe, with hollow walls, and the inner one was removed, before I knew it, to increase the size; but I soon gave up using packings of straw, having come to the conclusion that, on the whole, from getting damp it did more harm than good. When either a stone, brick, or wood house is raised partly or wholly above the ground level, covering the single wall, whatever it is, with from 6 to 9 inches of straw neatly fastened on the outside, and with the eaves of the roof projecting far enough to keep that straw dry, will be the best substitute for a double wall; and if the ears of wheat are removed, so as not to entice birds or mice, the straw will last a number of years.

Thus by using hollow walls, or a non-conducting medium, it will be seen that regular ice-houses may be as well, partly or wholly, above ground as below it; and in the

circumstances of soils retentive of moisture, much better above than below. When so built, and near the mansion, they could be turned to many useful purposes, as respects keeping meat and vegetables, with more economy as to ice, than when the ice has to be brought in pails and barrow-loads to the house.

So much for the place: now for the filling. The chief thing is to get ice from good clear water, and pound it well outside, but chiefly inside, of the house. If the water is not clean the ice will be unfit for preserving many things where fine flavour is an extra consideration. Every space of air enclosed between pieces of ice will hasten the decay of the ice whenever these spaces can gain access to the air above them. When filling in frosty weather it is a good plan to use a little water for filling up the crevices, which soon freezes the whole into a compact mass. All ice with leaves and pieces of wood in it is to be rejected if better can be had, as they will make a sort of free space round themselves long before the summer is passed. In packing it is advisable to keep the centre the lowest, and the outsides the highest, so that the moisture contained may find its way to the centre and there be frozen, instead of passing through the ice at the outside and escaping. This same rule should also be attended to in taking the ice out of the ice-house. It is impossible to break the ice too fine—the more like sleet and snow the better, and the firmer packed the better. This is even more necessary when the house for keeping it is small.

As to keeping ice when obtained, the great object is to prevent it being surrounded with a moist stagnant atmosphere. A dry air, though warm, will exert much less influence in melting the ice than a damp air though cold. Two facts tended to alter my views on ice-keeping. First: So long as the ice was above the doorway, or even somewhat above the ground level, it kept very well indeed: because, I imagine, there was so much less moist air in the house, or air of any kind, and until it sunk somewhat lower it came less under the influence of the increasing heat of the summer acting on the ground surrounding the ice. The second fact was, that in opening such a house in summer, after the ice had sunk considerably, a stream of foggy air issued from the door like the vapour from a wash-house copper. I used to be anxious not to have the doors open a moment more than was necessary; but I found that the dry hot air of a summer's day melted the ice less than this moist air hanging about it. The dry warm air, however, did melt the ice when playing at once upon it. A dry non-conducting medium over the ice, was, therefore, seen to be important, and likewise some simple mode of getting rid of the moist air. Both can easily be managed in unison with increased usefulness from the ice-house; as, without such precautions, meat and vegetables, though placed there, will be kept there at the expense of flavour. These evils will be remedied by keeping the air over the ice dry and in movement. Have a hole in the door from 2 to 3 inches in diameter guarded with fine wire, and a plug to regulate the draught, and have another of a similar size in the roof, regulated in the same way, and then fog can hardly accumulate. Spread a clean cloth over the surface of the ice, split up the middle, so as to be moved easily to either side when you wish to place articles on the ice, and cover the cloth with 6 or 8 inches of clean straw, to be changed when it shows the least signs of mouldiness. The air thus admitted clears off the vapour, and does not act on the ice, owing to the straw on the surface—the only place where, as already remarked, I consider straw to be useful in a regular ice-house. In practice, I may here state, that I never satisfied myself that salt or salt water was beneficial for keeping ice in ice-houses or not. Sometimes I thought it did service, sometimes the reverse. The science of the matter is somewhat conflicting. Where very low temperatures are wanted, of course salt will be used with ice, and especially with snow, but in such cases it must be used with caution, or there may be too much freezing.

Houses for ice, however, whether below or above ground, and of whatever they may be built, are chiefly used for preserving various matters in them, and for such purposes should be near the mansion. When ice is merely wanted to be taken to the mansion it may be preserved in ice-heaps just as well as in an ice-house, and in some respects even better. The principles of action are the same, but the carry-

ing-out of these is a little different. Of two favourite positions for an ice-heap we should select, when we could get it, a level space some 24 feet or more in diameter, with a sloping bank above it on one side, and a slope or dell below it on the other. In such a place the ice could be brought to the top of the bank, broken there, and then sent down an inclined plane, in the shape of a trough, to where the centre of the heap should be. Suppose the heap were to be a cone some 16 feet in diameter, and to be raised 10 or 12 feet to a sharp point, then the base for 18 feet or so should be raised, and the ground slope from it on the bank side, as well as the other, and a little ditch be made there, so that no rains on the ground near it should reach the ice. A few pieces of wood, a layer of faggots, and then some litter or stubble, will make a comfortable bottom. This bottom not only secures dryness, but prevents the heat of the earth in summer greatly influencing the heap from below. Men must keep the heap in a proper form, drawing it in gradually from the base to the summit, and using a little water if the ice is too hard to build nicely. The next best position is an open space, with a natural hillock for its centre. Prepare the bottom in a similar way; but here there will be less danger of water. Carts may be emptied on either side, and the ice shovelled up and put in its place when broken. A cone of that size will require about thirty good loads of ice as taken from the water. The more compactly it is built the better it will stand. Though generally built in round heaps, yet an oblong parallelogram would answer equally well. The great thing is to have a sloping side to throw off the wet; and it is of little moment whether a person has one large heap or several smaller ones. When heaps are made oblong, something like a huge Potato-pit, of course the opening to take out ice will be made at one end, in a round one at one side. Much depends on keeping the opening exposed as short a time as possible.

However built the sides must not be too steep, or the coverings will not be easily kept on. When finished as firmly on the sides as possible, it is advisable to wait for a frosty night before covering it; and if that should not come a good shower will do it good, as it will make the outside a dense sheet of ice.

Snow rolled in heaps when well consolidated, and a little water used to enable the workmen to compress it, is little inferior to ice, either for ice-wells or ice-heaps. When a good fall takes place, and there is an open park to go to, it is easy to get a great quantity of it when fresh fallen, or when there is a slight thaw. When hardened, however, a little on the surface with frost or wet, it is vain to attempt to roll it into heaps.

The heap being made and finished, the next thing is to cover it up securely. A layer of 3 inches or so of clean wheat straw should be placed all over it. After that, when possible, the covering next the straw should be of an open nature, and the very outside rather of a close nature. Provided the outside air does not penetrate, the more air enclosed between the outside covering and the ice the better it will keep. Thus, after the straw, we have seen 9 inches of rough stubble put on, and the outside formed of 9 inches of tree leaves. Again, we have known small spruce or larch faggots used above the straw for a foot in depth, and then a thatching of straw from 9 to 12 inches thick, and both answered well. Where tree leaves can be easily obtained, I would prefer 3 or 4 inches of clean straw, and then 6 inches of leaves at first, increasing the amount gradually to 12 or 18 inches of leaves, according to the heat of the summer. When these are once settled it takes a very strong wind to dislodge them, and if the sides are moderately steep rain passes freely down the outside without penetrating to any extent. If the above amount of leaves were put on at once, they might be liable to heat. Vermin rather dislike burrowing in the tree leaves. Any other substance will do, provided the same conditions are observed.

One thing we must guard against, as a cause of failure. Some people, extra careful, put a rough frame over their ice, and the covering over it. I never saw one case in which such a mode answered well. When the ice sinks the frame does not sink with it, vacancies are formed between the ice and the coverings, these get filled with moist vapour and melt the ice, or sometimes holes are also formed in the covering, by which the warm air outside has free entrance

to the heap. By placing the covering at once on the ice, the covering sinks as the ice sinks, and no space is given for damp vapours, nor yet much chance for any openings being formed. At any rate, I have never seen these kindly-intentioned rough frames used but disappointment more or less was the result. It would be better to construct a wood house at once, and have an air-tube in the roof and doorway. In heaps nothing should come between the ice and the covering.

Several inquiries have been made as to whether an American or Cobbett's ice-house would not be preferable to houses or ice-stacks; and also requesting a short outline as to the mode of making them. First, then, as to making. Choose a suitable spot where you can describe a circle some 19 feet in diameter. In the centre fix a post 10 inches in diameter, and 15 feet above the ground level. Describe a circle 10 feet from the centre, and in this circle, at regular intervals all round, fix fifteen posts, 9 feet above the ground level, and about 6 inches in diameter. Connect these with a plate at top. In the outer circle of 19 feet you will want fifty-four posts, 5 feet high, and each some 5 inches in diameter. These also are to be connected with a wall plate. The centre pole will at its top form the apex of the building inside. Any carpenter will know how to put on the rafters, so that they may extend beyond the outer line of posts. These will be thatched with 4 feet thick of clean straw. The space between the outer and inner rows of posts is also to be filled with straw closely packed, and, of course, there will be a doorway, or rather two, with a space between, for admittance. The ice is kept in the ten-feet circle.

Now, we do not think there would be any economy in the use of such a house in many parts of this country—first, owing to the posts not being thickly enough placed to prevent our shorter straw from bulging; and chiefly because, independently of the yearly sinking of the straw, and the necessity of fresh packing, in most country parts it would be almost impossible to prevent such a building being burrowed in by vermin, and the holes would admit air to the ice. Our opinion is that a building of wood, brick, or stone, with double walls, would prove the most economical in a few years.

One word more. When ice has to be taken to the mansion for various purposes, the preserving of it as long as possible is a matter of some importance. Ice-tubs are, therefore, very useful for the superintendent of the kitchen or the cellar. They may be made of any size or shape. We have a very useful circular one near the cellar, 3 feet in diameter at bottom, outside measure, 30 inches in diameter at top, and 3 feet in height. The bottom is formed of wood some 4 inches thick, the sides of the same 3 inches thick, lined inside with cork 1 inch thick. It is supplied with two lids, one thick, and similarly lined, that fits into a groove, so as to be on a level with the circular outside; the other to go over that, and come down a couple of inches over the outside. It used, also, to be lined with woollen cloth, but that seemed to be of little consequence. It is painted outside of a whitish colour. There is a small iron vessel fixed inside that would hold somewhere about two gallons of water; and, there being a pipe from it communicating with a tap outside, there is always a ready command of iced water during the summer. Bottles of wine, &c., are merely placed among the ice. Though this tub stands in an airy place, the ice keeps a good while, if the lid is not often opened.

If some of our humbler friends desire a glass of cool water in summer, the simplest plan to obtain it is to fill a porous earthenware bottle and set it full in the sun, with a woollen cloth fastened round it, and that cloth kept wet. In such circumstances the hotter the sun the cooler will the water become. Though a glass of such water is considered a luxury in hot weather, we question much if the frequent use of it would be conducive to health.—R. F.

CHANGING OCCUPATIONS.

I HAVE been a reader of your Journal for one year and a half, and at present being almost unable to decide what to do, I write to you for advice.

Though I have taken your Journal for the time stated,

yet I am not a gardener, but a tailor in a country village in Yorkshire; and the reason why I ask for your advice, is because I have such bad health with my present trade, that I should like to become a gardener. If you could inform me how I am to succeed in getting a situation in the gardening line, you will greatly oblige—**A YEAR AND HALF SUBSCRIBER.**

[We would willingly aid any one who is in bad health. You do not say a word about your age, nor what you have been in the habit of doing beyond your trade, nor whether you have tried gardening much in practice and detail. For a man to change his occupation or trade is always a matter productive of very important consequences. The very best excuse for doing so would be want of health. Where the constitution is not materially injured, a change of occupation will often effect a great measure of benefit, especially where there is a natural bias or aptitude to the peculiar trade that is selected for adoption. We should not be surprised if gardening morning and evening would renovate your health, and thus enable you to follow your first calling. We have known village tailors become almost independent gentlemen in their circumstances; but it is rare, and the

instances are few and far between, in which working gardeners can do much more than merely make their way. Recollect all is not gold that glitters. The glittering gold that comes to the gardener, as well as much of his payment, will consist in the belonging to "such a pleasant and delightful occupation." Be certain that you can make a little reality out of the poetry and romance of the occupation before you give up making garments. To make sure of this matter, try and get as a labourer into a nursery or gentleman's garden for a month or so, and then you will be more fit to judge whether you had better change your occupation or not. You will have little chance of getting a situation for yourself worth holding, until you have been some time in practice. We have known several cases of hard-studying clergymen who suffered frightfully from that scourge, tic douloureux or neuralgia, and who obtained no relief until they became active gardeners, working hard every morning and evening amongst vegetables and flowers, and from the fresh air and fresh-turned earth getting fresh vigour into their physical system. Try this and a short time as a labourer before you decide.]

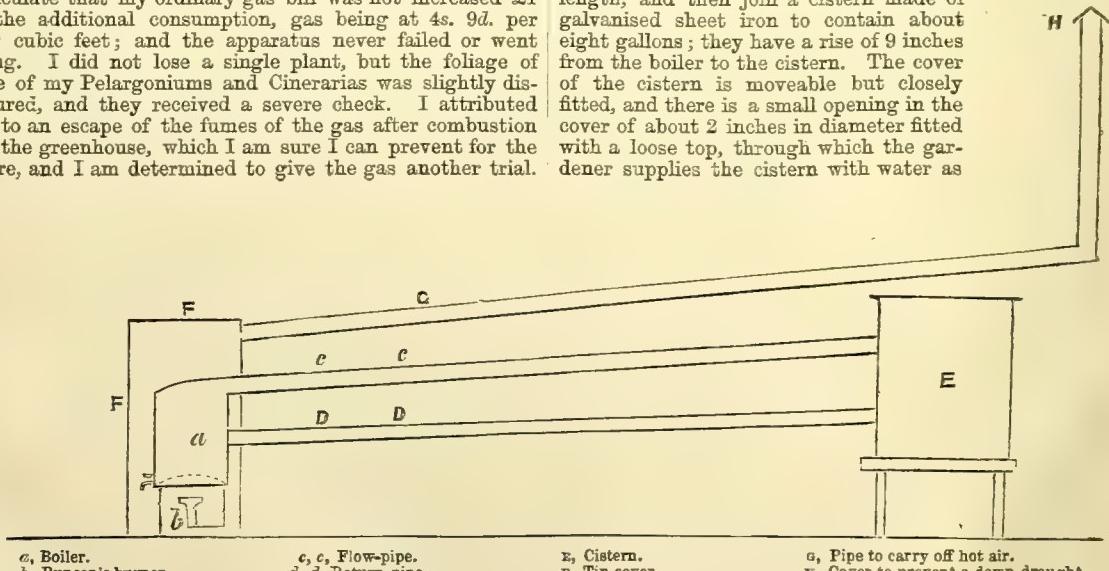

HEATING BY GAS.

AN article on this subject which appeared in your Number of the 7th of June induces me to send you my experience of heating a greenhouse by gas—with what success you can judge.

I found myself last season with a house extending over an area equal to 30 feet by 11 without any means of heating it. I was in favour of gas from its manifest advantages to an amateur; and in the face of much dissuasion I decided to set up a slightly formed circulating hot-water apparatus, heated by gas from a Bunsen's burner. I was able easily to keep the temperature in the house up to 40° or 45° in the most severe frost of last season. I had to light the burner about five minutes past four or five o'clock at night; and I calculate that my ordinary gas bill was not increased £1 by the additional consumption, gas being at 4s. 9d. per 1000 cubic feet; and the apparatus never failed or went wrong. I did not lose a single plant, but the foliage of some of my Pelargoniums and Cinerarias was slightly discoloured, and they received a severe check. I attributed this to an escape of the fumes of the gas after combustion into the greenhouse, which I am sure I can prevent for the future, and I am determined to give the gas another trial.

I will describe the whole apparatus, as I think it probable that some of your readers may, like me, be glad to avoid the trouble of attending to a fire in the middle of a winter night.

The boiler, made of copper, is cylindrical, set on end. The bottom is 9 inches in diameter, and is slightly concave to collect the heat, and the top convex to an equal degree. It is placed on a skeleton iron stand, which raises it about 9 inches above the floor of the house, leaving only sufficient room for the burner underneath. From the boiler are two pipes, one from the middle of the side, the other over it as high as it can be placed (in fact ordinary flow and return pipes), of two-inch gun-barrel tubing; they are 20 feet in length, and then join a cistern made of galvanised sheet iron to contain about eight gallons; they have a rise of 9 inches from the boiler to the cistern. The cover of the cistern is moveable but closely fitted, and there is a small opening in the cover of about 2 inches in diameter fitted with a loose top, through which the gardener supplies the cistern with water as

a, Boiler.
b, Bunsen's burner.

c, c, Flow-pipe.
d, d, Return-pipe.

e, Cistern.
f, Tin cover.

g, Pipe to carry off hot air.
h, Cover to prevent a down draught.

it is exhausted. This top is useful to allow of evaporation in case the air of the house becomes too dry. There is a stopcock at the bottom of the boiler to draw off the water if necessary. The top of the burner is about 3 inches under the bottom of the boiler, and in an hour and a half it will make the water nearly boiling hot. In fifteen minutes it will sensibly affect the temperature of the house.

Most skilful gas-fitters understand Bunsen's burners. They are constructed to burn atmospheric air and gas together, the result being a clear flame almost free from smoke, giving out great heat but only a little light. Such is the entire heating apparatus, which is certainly capable of keeping

frost out of an ordinary greenhouse. But an addition to it has yet to be described; for, judging that the fumes of the gas if allowed to escape through the house would be deleterious to the plants, I had the boiler and burner all enclosed by a tin case set against the wall, and plastered round where it joined the wall to keep it close. A door in it allowed of the gas being lighted, and I think the escape which damaged the plants was about this door. A two-inch tin tube the entire length of the house, and then passing out, served to carry off the fumes of the gas; and the hot air passing through it aided materially in warming the house. I intend this season to have the door in the tin

case soldered up, and one opened through the wall of the house instead (12 inches square will be ample), leaving no possible means for the gas to escape into the house. One great advantage of heating by gas is, that all the heat generated is available inside the house, none of it is lost. An apparatus such as I describe ought to be set up for about £6.

I found only one drawback in using this apparatus—viz., that a considerable quantity of water is precipitated by the combustion of the air by the Bunsen's burner (I would say as much as half a pint every night). This water flowed over the floor of the greenhouse, and kept it rather in a mess at that part of it, and I was informed by an eminent gas-engineer that this water was deleterious. It might have been the evaporation from it that injured the plants. However, as it will be precipitated altogether within the tin case, an arrangement can be easily made to make it flow off to the outside of the greenhouse by a small aperture left for the purpose.

I cannot agree with Mr. Wills that it will be better to apply the heat direct by a flue or pipe, at least when heating a conservatory. I think that the circulating hot water is necessary to fix and diffuse the heat through the house and give it out gradually. In the way that he uses it the earth lying on the pipe would produce the same effect as the hot water, but the apparatus must be made of light materials. A friend of mine lately set up one after seeing the result of mine. His gas-fitter would not have the light materials, but used the heaviest four-inch metal pipes; and when his apparatus was set to work, he found he could not get as much heat with thousands of feet of gas as I did with hundreds.—S. J. H.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

MACLEANIA SPECIOSISSIMA (Splendid Macleania).—*Nat. ord.*, Vacciniaceæ. *Linn.* Decandria Monogynia. Native of Columbia. A lovely flowering shrub, flowers scarlet tipped with yellow. Requires to be placed on a bracket, in a warm greenhouse, that its branches may hang down.—(*Bot. Mag.*, t. 5453.)

DENDROBIM MARGINATUM (White-edged Dendrobium).—*Nat. ord.*, Orchidaceæ. *Linn.* Gynandria Monandria. Introduced from Moulinne by Messrs. Hugh Low & Co. Flowers white, lip spotted with orange; lower lobe orange, but white edged.—(*Ibid.*, t. 5454.)

MICRANTHELLA CANDOLLEI (De Candolle's Micranthella).—*Nat. ord.*, Melastomaceæ. *Linn.* Decandria Monogynia. Native of the Andes at an elevation of from 9000 to 10,000 feet. Flowers purple, with very prominent yellow anthers. "Well suited for greenhouse cultivation."—(*Ibid.*, t. 5455.)

MECONOPSIS ACULEATA (Prickly Meconopsis).—*Nat. ord.*, Papaveraceæ. *Linn.* Polyandria Monogynia. "We had the good fortune to have this rare and charming plant flowering in the open border in the June of the present year." Native of the Kumaon and other South Indian mountains at elevations of from 10,000 to 14,000 feet. Flowers large, purplish blue.—(*Ibid.*, t. 5456.)

CYMBIDIUM TIGRINUM (Spotted-lipped Cymbidium).—*Nat. ord.*, Orchidaceæ. *Linn.* Gynandria Monogynia. Native of Tenasserim Mountains at an elevation of 6000 feet. Introduced by Messrs. Low & Co., Clapton Nursery. Flowers cream coloured; lip with short crimson stripes.—(*Ibid.*, t. 5457.)

AZALEA—*Souvenir de Prince Albert*. White, with centre of each petal blotted with deep pink.—(*Floral Mag.*, pl. 201.)

AURICULA—*Lord Clyde*. Raised by Mr. Lightbody. Dark maroon, paste rather too angular, but solid.—(*Ibid.*, pl. 202.)

OENITHOLOGALUM THYSROIDES.—Introduced by Messrs. Carter from Natal.—(*Ibid.*, pl. 203.)

FUCHSIA—*Cloth of Gold*. Raised by Mr. Stafford, of Hyde, near Manchester, "a golden variegated-leaved sport of Souvenir de Chiswick."—(*Ibid.*, pl. 204.)

WALLFLOWER—*Graham's Yellow Perfection*. Raised by F. J. Graham, Esq., of Cranford. "Pure yellow, large size, good form; received a commendation at South Kensington as a beautiful, bright-coloured, hardy spring flower, remarkably sweet-scented."—(*Florist and Pomologist*, iii. 145.)

CHICKENS VERSUS GREEN FLY.

The subjects of which the two parts of this Journal treat—gardening and poultry-keeping—are usually supposed to be antagonistic. Poultry are gardeners' detestation, for they believe that their trim gardens are sure to be spoiled by them. Build up the wall of separation high; let not the fowls, the awful fowls, into the sacred garden; they peck, they scratch—in short, "My good sir," exclaims the gardener, "don't, please, even name the horrors to me; I shall dream about them, and wake in a fright."

Now, for some years I have held, up to a certain point, an opposite theory, and carried it out in practice by keeping a few bantams, which have access to every part of my garden, being quite sure that they do more good than harm. As a case in proof: the other day I was walking among my last year's budded Roses, brushing off the green flies with a painter's brush (the best and most efficacious thing I know; indeed, I usually carry a short one in my pocket for the purpose), when some-six-weeks-old chickens happened to be near, and first one and then another tried a green fly or two, and they settled that they were very good eating. I encouraged the chickens to follow me; so I went from Rose to Rose, brushing the tender shoots and buds, and finally, before leaving each tree, giving a shake of the stem, when down rolled the already-disturbed troublers from the leaves, to which in their perplexity and distress they were clinging; once on the ground they were eagerly eaten by the chickens. Pleased with my success, I then went to another part of my garden, to my old standards, calling to me another brood of chickens of a similar age. The same scene was again enacted, and in addition I threw every grub I found, green, or white, or brown, to the old hen, which accepted my offerings with manifest delight. Thus I managed to dislodge and put beyond all power of re-appearance some thousands of green flies, at the same time giving a treat to my chickens.

I see that suggestions are sometimes made that poultry-lovers should communicate their experiences, so I send one of mine.—WILTSHIRE RECTOR.

GARDENERS BENEFITED BY TRAVELLING.

THERE is a good old rule in Germany which has not yet become quite obsolete, that every apprentice should be obliged to travel for three years before he is permitted to open business on his own account. I have the honour of belonging to a little scientific society in London, formed of members anxious to study the great natural laws which have brought about the changes in our globe, and which are combined into one universal science—Geology. The President of that society is one of the greatest scientific men of the day, and, at the same time, he is almost entirely self-educated. I attend the meetings of that society whenever opportunity permits; and one of the points which are most frequently brought to our notice is the desirability of visiting different parts of our own land for the purpose of personally observing the effects of these phenomena, and the President is fond of showing us how easily this may be accomplished. Thus the subject has been repeatedly brought before me, and I believe that it applies with greater force to gardeners than it does to the members of any other profession.

The gardener who has learned and practised horticulture in his native country only has done but very little towards making himself proficient. He should travel as far and as widely as he can, in order to study the different effects of soil and climate, the various artifices which each renders necessary. The system of gardening carried on in a sandy arid country is altogether different from that which must be practised on a tenacious clay. While in one place he visits he will find it necessary to take advantage of every scrap of sunshine with which the spot is favoured, he will find in another that the sunshine is more injurious, and has more carefully to be guarded against than the severest frosts experienced in another place. With regard to cold, again, he will find in one place that a tiffany house will protect, during the winter, plants which require double sashes, straw mats, and all the appliances which can be invented at a place not much more than five hundred miles away. Then

again, a gardener can seldom visit a garden at a little distance from his own without seeing something worthy of note. Every horticultural establishment managed by a thinking man (no matter how small it may be), is sure to present to the notice of the visitor some feature which is worth being remembered—something to think upon and carry into practice whenever the chance comes. The further he travels from his own locality the more numerous these examples will become. Travelling, combined with a certain amount of observation, which is easily attained, will enable a gardener in a very few years to obtain an immense supply of the raw material, which, being properly worked-up, will place him in the front rank as a practical gardener. Our young men, generally speaking, are in too great a hurry to get into good places. They would get far better situations, and be very much better fitted to fill them, if they would only quietly work on for a few years longer, working as assistants, and travelling as far from home as they can manage.

But it may be said that this is all quite visionary. I may be, and often have been asked, "How is a young gardener, earning only some 10s. or 12s. per week, to afford to visit the distant parts of his own country, much less foreign lands?" My answer is that "where there's a will there's a way." I could bring forward more than one example to prove this. I know one young gardener who, having finished his apprenticeship, worked in several gardens at 12s. per week, sometimes with, sometimes without the advantage of a booby. I knew him more than once give up 15s., to which his pay had been raised, and go to work at another place, where he could learn more, at the old wage of 12s. Once, for a short time, he got as far as 18s., but this he gave up for a situation at a considerable distance, where he only earned the old pay. While working in these places he saved enough money to carry him across to the continent. He got a situation and worked there for some time. He visited Holstein, Hamburg, Prussia, Austria, Saxony, Hanover, and Belgium, as well as a number of the smaller States. He learned the language sufficiently to be able to converse in it with considerable fluency. He did not travel through these countries as one does who runs over to the continent for a month's holiday, but did much of it on foot, visiting the gardens most worthy of note; or, when the railway was resorted to, the journey was done in short stages. All this cost, in excess of what little he earned there, not a shilling more than £9. He has ever since declared that it was money well expended. He did not extend his travels so far as he intended, some domestic circumstance bringing him back to this country just at the time when he had got another situation at Frankfort-on-the-Maine, intending to make that the centre of a more southern series of journeys, and hoping to visit Italy, and return by way of Switzerland and France. I take this simply as an instance of what may be done upon very small means. I know that the person spoken of had not a penny more than he had saved while working upon the rates of wages mentioned above. He did not get help from home, as many young gardeners do, to their great injury, nor did he while saving that sum deny himself any of the necessities, and some few of the luxuries of life.

The money expended upon travelling is like a sum placed at your bankers, and bringing in a good rate of interest all through life. You can always discover whether or not a man has seen much of the world, even if you only have ten minutes conversation with him upon any subject, no matter what. You find that he is not so full of prejudices; he gives credit where credit is due; he does not think his own country is the best spot upon the face of the earth in all respects; he is willing to believe that other systems of gardening are as good or better than that he practises, and he is ready to adopt and incorporate with his own every good and practical idea. Let me illustrate what I have advanced by one or two practical instances. Kitchen gardening may be very well carried out in many private gardens in our country; but very few of them would bear being measured by a debtor and creditor account if the matter of rent were also taken into account. Will the value of the vegetables and fruit produced balance the expenditure in labour, manure, &c.? It is not, perhaps, expected that it should do so. So much the better for the gardener.

There is not a young gardener in the country who would not be the better for a twelvemonth spent in a market garden near London. High rent and heavy rates have to be paid there, and yet market gardening is far from being a profitless business. He would there learn how to economise to the utmost; how to insure the greatest possible supply from the smallest space; how to get three or four crops a-year from the same ground; and the way in which not even a rod of ground is allowed to be idle for more than a day. The young gardener, in order to see how this was managed, would have to work very hard upon very small pay; but he would in that year learn what would be invaluable to him through life. He might, perhaps, attain the same end by getting a situation in the neighbourhood, and carefully watching the proceedings at some market garden near him; but this, of course, would not be equal to working upon the spot. Then, again, to take another and widely-different instance, we may say that if half the precautions taken in Germany to secure plants, which we consider hardy, from the effects of frost were practised in this country, our gardens would present a much more interesting appearance. What would a British gardener think of a Deodar with all its branches carefully packed together, and then thatched over with reeds or straws for four months in the year? And yet that and many other expedients are there regularly carried into practice. If the same trouble were taken with plants which are half-hardy here, how many more species might we not cultivate? All the beautiful South Australian plants, those of Chili, Japan, California, and many other parts, might then be freely introduced, and would have a glorious effect. I am trying this now with a *Dasyllirion*, a species of *Eucalyptus*, and some others. Two winters have been safely got through. Then, again, a season would not be lost in watching the care taken in the growth of bulbs in Holland and Germany. But I might go on multiplying instances of the things worthy of observation to an almost unlimited extent. Forcing as practised in various parts, the different modes of ventilating houses, the management of timber on forest lands, and a score of examples might be quoted.

The means for getting about from place to place are now very much greater than at any former time; cheap excursion trains are plentiful, and steamboats will, for a few shillings, take one a long distance. Indeed, if one only has the wish, he can now readily travel very cheaply from one end of the country to the other. No young gardener who seriously intends to educate and fit himself for taking a high stand in his profession should neglect the opportunities with which these furnish him. He should take advantage of them to visit and observe as much as he possibly can, and in so doing he will surely find his reward. Travelling is one of the luxuries which were formerly confined to the rich, but it is now within the means of everybody; it is no longer a means of education which the wealthy alone enjoy.

To prove that I practise what I preach, I may mention that this paper was commenced at a spot six hundred and fifty miles away from that where it is now completed, and it has to be sent three hundred miles by post to the place where it will be printed—glorious Auld Reekie.—(*Scottish Gardener.*)

WORK FOR THE WEEK.

KITCHEN GARDEN.

Ply the fork incessantly amongst the growing crops of Cauliflower, Broccoli, and Winter Greens, and continue to manure and trench up every piece of ground as it becomes vacant, and plant it with such as the above for late crops. Celery, prepare trenches for the late crop, water the growing crops of the same, and stir the soil about them. Cabbages, reserve and get ready a patch of ground for the sowings of Cabbages to stand the winter. The soil should be of a light, sandy nature, and not too rich, as such encourages a luxuriant growth, which is apt to make them tender. Endive, plant out the strongest from the early sowings, and sow also more for late crops, the Small Green-curdled is the best. Garlic and Shallots to be taken up and dried for storing. Onions, pull up the crops of winter Onions, lay them in rows with the roots turned to the sun, and frequently turn them until the

stalks are withered, when they will be fit for storing. As they are liable to decay if bruised, they should be carefully handled, and not thrown about like so many stones. Let them be very dry when stored, and spread out thin, not laid in heaps. *Lettuce*, sow also more, and keep a good succession of Radishes and Salads. *Peas*, the late-sown should have attention paid to watering and staking. *Potatoes*, the lifting must be prosecuted as fast as they become ripe. *Spinach*, a good breadth sown now in rich soil will afford many successive pickings in the autumn, and will tend materially to save the winter beds from being picked before they become strong.

FRUIT GARDEN.

Espalier Apples and Pears to have the leaders tied in, the superabundant shoots spurred, and the fruit well thinned. Attend, also, to choice Apples and Pears planted in the open quarters, but not trained; remove superfluous shoots, and try the effect of tying downwards the points of some of the strongest shoots. It has been practised with very good effect on trees inclined to grow too luxuriantly. Attend to the stopping and nailing of wall fruit trees in general, and prosecute the thinning of Grapes on the open walls. Remove all runners from Strawberries not required for making new plantations. Fruit trees generally may now be budded.

FLOWER GARDEN.

Dahlias that have attained a good size to have their side shoots properly thinned out, leaving three or four of the strongest and best-set shoots. Examine the fastenings carefully; if they have got too tight and are cutting the stem remove them, and retie them, allowing plenty of room to admit of the stem increasing in size. See that the pots on the top of the stakes are gone over every morning, and all the earwigs that are found destroyed. These insects, in common with others, are very numerous this season. We find that a little soot sprinkled on the plant when wet with dew is an excellent preventive to their ravages; as long as that remains they will not touch the foliage. Cover the blooms of Carnations and Picotees as they expand, placing cardboard collars beneath them. Layering may be commenced, beginning with the grass or shoots which are most forward. As the Pink pipings root, prick them out in good soil. Trimming, staking, and pegging-down must be well followed up at this period, where neatness and order are essential. See that sufficiently strong stakes are applied to plants with heavy foliage and gross habits, such as Dahlias, Hollyhocks, Larkspurs, Phloxes, and tall-growing Aster. Keep Roses as much as possible free from insects, and if time can be spared, dead blossoms should be removed. Budding may be proceeded with. Proceed with the propagation of favourite sorts which it may be desirable to increase, either by budding or cuttings. It is generally preferred to have the Hybrid Perpetuals, Teas, Chinas, and Bourbons, on their own roots, and firm short-jointed shoots of these root very freely at this season. To insure success they should be afforded a slight bottom heat, be carefully shaded, and not kept too warm until they emit roots. They will, however, root under a hand-glass on a shady border. Remove suckers from worked plants. Cut back the shoots of the autumn-flowering varieties to the most promising eye as soon as all the flowers are expanded and begin to fade.

GREENHOUSE AND CONSERVATORY.

This is generally a critical month with the greenhouse plants out of doors. The fervid heat is sometimes so great as to produce the tropical winter of vegetation, when the parching heat of the sun acts upon, and produces in some degree a dormancy in the system of plants; at other times when occasional showers fall, and we see the surface of the soil in the pots moist, we are satisfied until the drooping or withering foliage upbraids us for our neglect, and often, particularly with Heaths, New Holland, and other such plants, it is noticed when too late to save them. The ill effects may be avoided by plunging the pots in coal ashes, and syringing the plants overhead of an evening, and examining them when doubtful on the subject, by gently turning one or two out of their pots to see the state of the ball, as it requires some experience to distinguish whether a plant wants water or not from the ring produced by rapping your knuckles against the side of the pot. The

conservatory will now be gay with Balsams, Globe Amaranths, Fuchsias, Pelargoniums, Cockscombs, Thunbergias, Japan Lilies of sorts, and the rafters and trellises with creepers arranged in festoons, or in any other manner most suitable to give a pleasing effect to the whole. The Camellias out of doors to be surfaced with fresh soil if they require it. The thinning of fruits and flowers is an operation that we generally perform with great reluctance; nevertheless, it is one of the most useful to produce fine fruit and flowers, and a regular annual succession of them: therefore, we would advise that the buds of the early-flowering Camellias should be gradually thinned, leaving ultimately only as many of the most healthy and prominent buds as the condition of the plant would bear without fear of injury to its strength and productiveness the following season. Cinerarias, whether seedlings or suckers to have regular attention, and those intended for autumn work to be potted forward without delay. The Chrysanthemums that had been planted out in May, and repeatedly stopped as recommended during the summer, will now be bushy plants. The last stopping may be given towards the end of the month to such as are intended for early blooming. The stopping of the others to produce a succession may be continued to the middle of August.

STOVE.

Encourage the onward progress of the young stock for winter blooming. Maintain moist and comparatively high temperature. Orchids must be carefully shaded during sunny days, but when the weather is at all cloudy allow them as much light as they will bear without injury. Keep the foliage clear of insects and dust, by frequent syringings or spongings as may be necessary.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

BESIDES taking up Potatoes and pricking out winter stuff, the chief work has been surface-hoeing among growing crops, alike to kill miniature weeds and keep moisture in the ground, and mulching with short grass and litter the sides of rows of Peas in full bearing and coming into bloom. We have been able to give but very little water, and even our sewage-tank has been emptied three times during the week. In such parching weather Cauliflowers can scarcely produce large heads unless they be liberally watered or freely mulched. For the latter purpose, nothing of a littery matter comes amiss, and as soon as the crop is taken it is dug down and thus helps the next one. Thinned out Cucumbers, which still continue to do well. Planted out some of the smaller Tomato plants against a wall, and turned out larger plants from large pots, the plants showing plenty of fruit, against the back wall of an earth pit, where they will receive pretty well as good help as if they were trained against a wall. These will ripen plenty of fruit before the cold weather comes. We have grown them plentifully against a wooden fence, and even on the open ground full in the sun; but in the latter case it was late before the fruit ripened, and very often it had to be gathered when merely changing colour, and to be put into a warm place to colour. In the latter circumstances, connoisseurs have informed us that the flavour of the sauce was inferior. To get the fruit ripe early the seed should be sown in March, and the plants grown on under glass until the end of May and then be turned out. To grow them late and where green fruit are a consideration, it is best to sow about the middle or end of April, and plant out in the beginning of June, before the plants receive a check. In managing them afterwards the chief points are—to stop the shoots a joint or two above the clusters of fruit as they show, and to remove all the foliage, or at least the larger leaves, that would at all shade the fruit. When grown in soil at all rich there is sure to be a superabundance of luxuriant foliage. This might be remedied by growing in poorer exhausted soil, but then the fruit will not be fine to look at nor yet so juicy. All things considered, we prefer rich firm soil, such as may be obtained by a couple of spadefuls of rotten manure to a plant, and then regular stopping and disleafing. Each leaf-stalk has generally from five to seven and more segments, and when such a stalk is not removed, from three to five of

these next the point are frequently taken off. This prevents the plants having a naked appearance. The stems are so juicy, however, that the plants will generally stand a good amount of disleafing. This is almost the only thinning that Tomatoes have, except when it is desirable to have a few very early fine fruit. In this case the above disleafing will have to be attended to, and all fruit on the plant, except the three or four first-formed clusters, should be cut off as they appear. When grown on the open ground they should be stopped and trained very much the same as Cucumbers are done. It is rather surprising that the fruit has been little used by us in the green state, or as a component part of salads, though largely used in this way by our cousins in America.

We are very anxious to defer planting out the *Winter Greens*, that have previously been pricked out, until the ground has been moistened, as, where other crops have been removed, the ground is excessively dry, and we can more easily keep the plants slowly growing where they are, in temporary beds, than supply them with water after planting. The planting has, therefore, been chiefly confined to turning out smaller plants by means of the dibber. In doing this we followed the good old custom of first watering the seed-bed before pulling up the plants, and then placing each handful of plants in a thin paint, made of water, soil, and rotten dung. By this means each plant, before being turned out, was well charged with moisture—a matter of importance when turned out into dry ground, and where all the watering that could be given was only a little drop close to the roots, extending little farther than the dibber hole.

If we recollect aright, we said something about planting by the dibber some weeks ago. We recur to it now because we have never seen a man, who had not been previously instructed, use the dibber without a great waste of labour power. Only the other day we counted the strokes made by an uninitiated person in satisfactorily fixing a Savoy plant, and found that the strokes for each plant averaged from five to ten; and then we could be quite sure that five out of the ten were hung—that is, all the potching had failed to fix the earth firmly about the roots, the chief thing to be attended to in dibber-planting.

We shall never forget how Mr. Joseph Knight, the predecessor of Mr. Veitch at the Exotic Nursery, Chelsea, taught some clever fellows how to make a pointed flower-stick, ranging from less up to more than half an inch in diameter, by two strokes of the knife. The first stroke in a sloping direction took away half the diameter of the stick at its base, the other stroke took away more than the half of what was left, and there was the stick pointed at once. Previously the sticks were receiving numerous strokes and whittlings. Just so with dibbling. So far as small things are concerned, two strokes are quite sufficient. For larger things in the open ground, three strokes may be necessary. First, There is the perpendicular stroke into the ground, to make the hole for the plant. Then, whilst the roots of the plant are suspended in this hole, there is stroke second, the dibber entering the ground two or more inches from the first hole, in a slanting diagonal manner, the point passing beyond the roots of the plant; and then a drawing quickly of the head of the dibber towards the stem of the plant leaves the roots and the buried part of the stem pretty well as firm as if they had been placed in the vice of a blacksmith. This is all that is necessary for planting. On removing the dibber, however, the hole left might admit too much air, and thus dry the roots of the plant. To prevent this the point of the dibber is drawn through the ground towards the planter over the mouth of the second hole, which just fills it sufficiently. Every patterning stroke beyond these three is just labour lost—a matter of no great consequence when only some half a dozen plants are to be put in, but a matter of some moment when the plants are numbered by hundreds or thousands. Besides, where many strokes are employed, the second diagonal planting stroke is apt to be given imperfectly. We recently noticed a row or two of young Cauliflower plants, that though refreshed with water once or twice, looked woe-begone whenever the sun rested on them. On inspection we found that the roots of almost every plant were hung when planted—that is, the earth was not firmed about the roots. Though numbers of patterning strokes had been given by the dibber, the second stroke we have alluded to had not been given,

and the slightest touch moved the plants out of the ground. Wheeled lots of fine, large, bolted Lettuces to the rubbish-heap, whence they might go to pigs to nibble. Without plenty of water it is next to impossible to keep them long in open positions. We were thankful we had lots on the north side of banks and walls, and beneath the shade of trees, where they needed but little water. Sowed Dickson's Favourite and Sangster's No. 1, early Pea; succession of Turnips, Radishes, Spinach, &c., and a bed of Kidney Beans, where they can be protected late in autumn.

FRUIT GARDEN.

Proceeded with laying *runners of British Queen Strawberries* in small pots, to be afterwards moved and potted. Would have done it sooner, but even now find we cannot place the pots down without injuring the fine fruits, and the watering of the little pots will also be apt to injure them. Most likely will cut off a number of runners and prick them out in rich soil 4 inches apart, and then lift in balls and pot for forcing. Keens' and Black Prince previously layered will soon be fit for being transferred to their fruiting-pots. These runners, just showing roots, will establish themselves quickly in beds if shaded from bright sun and sprinkled with water two or three times a-day.

This dry weather has brought on us whole clouds of birds. Nets they seem to laugh at. We have a small border planted with dwarf standard Cherries loaded beautifully, and the undergrowth British Queen Strawberry equally fine, and to save them we put a frame of posts to support the nets, and double-netted the whole; but as we went past yesterday morning five huge blackbirds were enjoying themselves, and singing out their notes of defiance. They one and all, with the impetus of a combined movement, broke through the net and escaped. The other day we stood at a short distance unseen, whilst a thrush went round and round the net trying to get his head in between the net and the ground, as, if they manage the head and shoulders, they will wriggle in the afterparts of their body. We had no gun with us, and if we had it would have been too bad to punish such patient determination. Lots of blackbirds and numbers of smaller birds escape by the same means, and when once they have found out this way of getting successfully in and out there is nothing that will stop them except killing them. A net is no safeguard unless put on securely. The very sight of it tempts them into the forbidden enclosure. We hope that plenty of rain ere long will furnish them with other moist food. We have been obliged to gather Raspberries just as they ripen to prevent the birds getting all, for as soon as the fruit was coloured they were sure to be at it; and so hard up are they for moist food, that the ground in some places is strewed with strings of Currants almost green, which they had pulled off to get one or two ripe berries.

Has any one ventured to decide how far there is a consciousness of doing right among the feathered tribe? What a contrast between the shrieking out "Murder! Murder!" cry of the blackbird, when he is thieving your fruit, and you approach him, and the graceful confidence with which the wagtail trips over the lawn, almost to your very foot, in pursuit of an insect; or the quiet deliberative hop from spray to spray of the white-breasted wall bird, in an orchard-house, looking so much at home in searching for insects as if he would like to be caressed, contrasted with a thrush, which, being disturbed at a Cherry tree, rushes to the end of the house, and stuns its faculties against the glass, which, if not strong, it also breaks. Why the seeming trust in the one case, and the terror in the other, but from some rather clear ideas of right and wrong?

If every tree and bush round a garden are to be sacred game preserves, the time is fast coming that, if we wish outdoor fruit, the fruit garden must be enclosed and covered all over with fine wire netting. Our old friend the robin, which we should be sorry to touch, is one of the most acute at getting under a net. None, however fine, will keep him out, unless it is fixed into, instead of on, the ground. Wherever he can pass his head between the net and the ground, he will get in and out his stumpy body.

The weather being so hot, we have just spattered a little whitened water on the orchard-house with a syringe. A very little dulls the force of the sun's rays. The first shower will take it off, and it is not likely we shall have much dull weather before we have rain, as, in dull weather, and in

moderate sunshine, the more light we have we like it the better—in fact, even now, the precaution taken has more reference to our water supply than to the force of the sun. We noticed a little spider coming on in two or three places in the orchard-house, and immediately we daubed all the open spaces on the back wall with flowers of sulphur, made into a paint with water and soft soap, so as to cause it to stick. We then shut up about three o'clock, and well syringed the trees. In three days we collected a handful of the worst leaves, about twenty; and though there were abundant traces of where the insects had been, we only detected one alive, and that sickly. The power of the sulphur is already going off, and so we will add a little more. The sulphuring should, indeed, have taken place before a trace of spider appeared. We have far more faith in preventives than in cures. Watered well the borders for trees on the back wall, and placed on the surface of the pots bearing heavy crops as much superphosphate as we could take up with the thumb and two fingers, and after watering we covered the surface with half an inch of rough riddled mushroom dung, to lessen the evaporation of moisture from the soil. The pots are also plunged for three-quarters of their depth, and that helps to keep the roots cool.

Gave a good watering to Figs; damped the floors of vineeries where the fruit was late. Stopped and set Melons, and frequently turned large fruit ripening, as when they lie long in one position on a flat slate, &c., a mark is apt to be produced, and the rind will be apt to crack there. We have not yet uncovered our Vine-borders wholly, but we wish the sun had played on them for the last few days. Figs when fresh watered want more air, as otherwise they are apt to crack at the sides before being thoroughly ripened up to the point.

A correspondent asks the best way for sending fully-ripened Figs to a distance. Will some friend tell us? For ourselves, we consider that a Fig just fit to be eaten—that is, like a globule of honey, will not bear to be carried farther than from the tree to the dining-room. When they must be packed they must be gathered before they are nearly so ripe as this, and though, of course, eatable after a long journey, they give no better idea of the lusciousness of a Fig gathered when fully ripe, than Peas conveyed to Covent Garden in sacks give an idea of nice young Peas gathered just before they are shelled and cooked.

Peaches in Peach-house have ripened faster than we wanted them, and we picked them frequently before they were quite dead ripe, as they keep better off than on the tree, and journey better in consequence. When fully ripe before being gathered and kept only for a short time, they become mealy and lose their rich juiciness. A good deal of tact is required to gather Peaches. The experienced man knows if they are ripe enough by putting his hand near them, hardly if at all touching them, as a touch is so apt to leave a blemish. A gardener who could scarcely be driven from his equanimity, did for once passionately jump out of it when a person who knew no better went along fingering every ripening Peach within his reach. This was even worse than a great gardener in a fit of absence of mind, going along admiring a house of Cucumbers suspended from a trellis, and picking off each bloom from the point of each Cucumber as he went along. "What are you at?" at last burst from the enthusiastic cultivator, who (as he told the tale), was so astonished that he could not speak.

ORNAMENTAL DEPARTMENT.

We intended to have had a gossip about the potting and general management of stove and greenhouse plants, but we would partly repeat the excellent timely directions of our friend Mr. Keane. The dry weather has rather browned our lawn in places. Mowing as generally practised was out of the question. Knifeing it so as to cut plantain and daisies was more in demand. The mowing machine even was little used, as it would have dipped rather deep, even when held with a light hand. In some cases the scythe was used lightly, and a good sweeping and rolling given. Of watering we need say nothing, for we have confined that almost to Calceolarias, and gave them only a little to keep them right. Most of the smaller things, as Verbenas and Calceolarias, have been slightly dressed with riddled old mushroom-dung. We could not give them more than half an inch, but we should have given them more if we had it.

Most of the Calceolarias were so treated a month ago, as the ground was quite hot enough for them. We are now giving the dressing partially to Scarlet Geraniums, as the ground is now hot enough to cause them to bloom freely. We would thus dress all our beds now if we had the material, as it saves much trouble in watering, and by keeping the roots near the surface encourages flowering.—R. F.

COVENT GARDEN MARKET.—JULY 16.

The market continues to be well supplied, and the demand is brisk. Pines, Grapes, Peaches, and Nectarines are sufficient for all requirements. Of Apples some good fruit of early kinds may now be had; and of Pears some excellent Jargonelles have come in from the continent. Strawberries are now falling off; the supply principally consists of Elton, with a few British Queens from later places. Of Asparagus, which is generally over by this time, some remarkably good samples are still to be had. Kidney Beans are beginning to come in quantity, and bring 7s. per half sieve.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BEURRE BOSC PEAR LEAVES (E. B.).—They are attacked by a parasitic fungus. We know of no remedy.

SEEDS FROM THE ROYAL HORTICULTURAL SOCIETY (S. E. H.).—The specimens you enclosed is *Erysimum Peroffskianum*. We are surprised by your complaint of the seeds sent out by the Society, because we never heard before of their being unsatisfactory.

MIMULUS FLOWER (*Mauchline*).—It did not reach our office until the 11th, and was totally dried up.

GAS BURNERS IN GREENHOUSE (M. C., Lymington).—They will be very injurious to the plants, unless within a stove or a glass globe, with a tube rising from it and passing into the outer air. We mention a glass globe because you may wish the gas to light the greenhouse.

STRAWBERRIES ON CHALKY SOIL (*Provincial*).—We have grown Strawberries on a Hampshire chalky soil; but we had to make the soil 18 inches deep of good loam. If you do this, and have the bed covered in the spring an inch deep with cocoa-nut fibre refuse, you will be able to obtain crops of Strawberries. We found Keens' Seedling, Comte de Paris, and Hooper's Seedling succeed well.

MUSHROOM-BEDS MAKING (W. W.).—We will be glad to give particulars when we have information as to circumstances and materials at hand. In the meantime see an article on the subject at page 447 in our Number for June 21st.

PLANTING TOMATOES (Idem).—It is of little use planting Tomatoes out of doors until the middle of June; but the seeds should be sown in March or April—that is, for cold positions north of London. We are glad you have noticed what we said about thinning them. It should have been referred chiefly to the foliage. As soon as the bunches of fruit show we stop the shoots above them, and the foliage grows so fast that we frequently thin it and shorten it, so as to expose the fruit more to the sun. The stems are so succulent that, like Nasturtiums, they will bear a good deal of disleafing and be the better of it—that is, if the roots have rich materials to grow in. In large clusters we have frequently removed the smaller fruit, but the thinning has reference chiefly to the foliage. We are glad the mistake has been alluded to. Those who know how most gardeners have to exercise mind and body at this season, will only be surprised that such mistakes are not more frequent.

FRUIT TREES FOR PEACH-HOUSE (H. E.).—We would have Violette Hâtive and Vanguard Peaches, and Erlinge Nectarine, with Barrington and Bellergarde Peaches for riders. Would it not be well to place the riders on the back wall? Any application of a paint to the Pear trees will be useful in spring. You can do little now except pick off the maggots, and syringe with clear lime water.

THRIPS ON BALSAM LEAVES (An Inquirer).—We found traces of thrips which nothing will remove but smoking, and then well syringing the plants when laid down on a cloth. The rusty appearance on the leaves is chiefly caused by the sun shining on the leaves when moist, from air not being given early. If kept too moist in rich compost they will also be thus affected.

AZALEA GRAFTING (W. H.).—There is no work specially devoted to so slight a topic. Side-grafting is best; grafts not more than $1\frac{1}{2}$ inch long, fastened to the stock with worsted. Best season for the process, early spring. The grafted plants to be kept in gentle heat in a close frame, or under hand-glasses in a propagating-house. The best time for Vine-grafting is early spring. The stock should be in a more advanced stage of growth than the scion.

MUSCAT GRAPES (C. D.).—They are very severely affected with what gardeners call the "spot." It may arise from want of moisture and warmth at the root, as you suggest; but we cannot give a decisive opinion, not knowing the temperature of the house, nor whether the vines are planted inside or outside.

LAWN—GREENHOUSE (Agnes).—Most probably a little thoroughly decayed stable-manure and earth spread over your mossy lawn would renovate it; but you tell us nothing about the nature of the soil, whether heavy or light. To heat your small greenhouse opening into the drawing-room, no plan would be more simple and manageable than a hot-water pipe passing round it, supplied from a gas-heated boiler. But not having a plan of the greenhouse, nor any other particulars, we can only give this general suggestion.

SULPHUR (A. B.).—Stone sulphur is not more powerful than flowers of sulphur.

EVAPORATING LIQUID MANURE (G. F.).—Mr. D. Thomson and other practical men have testified to the benefit derived by plants in heated structures from having liquid ammoniacal manures put into the evaporating-pans. The ammonia is mingled with the air and stimulates the plants. A little of the ammoniacal liquor from the gas-works mixed with water and put into the evaporating-pans would probably be equally beneficial.

NEW PEA (A. B. C.).—It is impossible to judge comparatively of a Pea without seeing it growing. From the appearance of the pods you sent us we should consider it belonging to the Early Green Marrow class, and, in that case, nearly related to Prizetaker, which is only eight days later than Sangster's No. 1, and, like yours, grows about 6 feet high. We should like to see the two growing together.

SPOTTED GRAPES (An Inquirer, E. A.).—The Grapes you describe as "damped," are what gardeners call "spotted," and yours are so very severely. You were wrong to syringe the Grapes after they had begun to colour. You could banish the thrips by fumigation, and keeping the air of the house moist by frequently watering the path and syringing the brick-work. If the roots are outside water them, put mulch over them at night, but remove the mulch during the day if fine and warm. It may be, whether inside or outside, that the roots have descended too deeply. In that case, lifting the roots in autumn to nearer the surface will be your only remedy.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

- JULY 19th, 20th, 21st and 22nd. NEWCASTLE-UPON-TYNE. *Secs.*, Mr. Wm. Trotter, Bywell, and Mr. J. Shorthose, Shieldfield Green, Newcastle-upon-Tyne. Entries close July 2nd.
- AUGUST 2nd. NEWMILLERDAM. *Secs.*, Mr. J. Turner, Walton, and Mr. W. Paschley, Newmillerdam.
- AUGUST 13th. WAKEFIELD AND WEST RIDING. *Sec.*, Mr. J. Crosland, jun. Thorne's Lane, Wakefield. Entries close August 4th.
- AUGUST 17th. COTtingham. *Sec.*, Mr. Joseph Brittain.
- AUGUST 18th. BURNLEY. *Sec.*, Mr. R. Whittam. Entries close Aug. 6th.
- AUGUST 22nd, 23rd, 24th, and 25th. ALEXANDRA PARK. Poultry, Pigeons, and Rabbits. *Sec.*, Mr. William Houghton. Entries close July 23rd.
- AUGUST 27th. HALIFAX AND CALDER VALE. *Sec.*, Mr. W. Irvine, Holmfield, Ovenden, near Halifax.
- AUGUST 30th. POCKLINGTON. *Sec.*, Mr. T. Grant. Entries close Aug. 22nd.
- AUGUST 31st. DEWSBURY. *Sec.*, Mr. F. Aked.
- NOVEMBER 28th, 29th, 30th, and DECEMBER 1st. BRIMINGHAM. *Sec.*, Mr. J. B. Lythall, 18, Temple Street. Entries close November 1st.

RULES FOR JUDGING POULTRY.

I HAVE been much surprised several times at articles in *The Poultry Chronicle* ridiculing the idea of judging poultry by

rules; and still more surprised that such articles apparently received, not your sanction only, but approval. I cannot understand how any one can for a moment seriously argue that poultry cannot be judged by rule.

It must be conceded that certain characteristics are essential to certain varieties of poultry. For instance: the Spanish fowl must have a white face and black plumage; the Polish a crest and so on. Put in other words, it is a rule that a fowl, to pass as a Spanish fowl, must have a white face; to pass as a Polish, a crest.

Does your correspondent who most persistently ridicules rules mean to say that he judges haphazard, and that no rules guide him? Surely he must have in his head some rules by which he determines which pens shall receive the prizes; and if so, what possible objection can there be to these rules, if correct, being reduced to writing and forming a code for poultry judging. I am surprised at Mr. Hewitt being opposed to written rules, for he evidently judges by rules. I know of no higher praise I can bestow on a judge, and can have no kind of reason for objecting to rules being written.—P.

[That Dorkings must have five claws, Spanish white faces, Polands crests, and so on, no one denies; those are the essential distinctive characteristics of the varieties, and no one suggests that their absence ought not to disqualify a bird; but when rules are attempted as to non-essentials, then we consider them objectionable. When condition has to be balanced against better uniformity in size, or when any one excellence has to be weighed against other excellencies in competing pens, then we say rules are objectionable, and the decision should be left to the judgment of the awarder.]

JUDGES AT THE APPROACHING ISLINGTON POULTRY SHOW.

THE correspondence of Mr. Tudman on the appointment of judges to the forthcoming Islington Poultry Show having left the matter in anything but a satisfactory position, I feel that some further explanation is due to exhibitors who are not members of the Club; and as one belonging to that class, I wish to be informed in the first place, whether Mr. Tudman acts from his own responsibility in such appointments, or under the direction of a Committee? I ask this not only because it does not appear that any other parties were associated with Mr. Tudman in the recent appointment; but further, because at the Ulverston Show, which, if I am correctly informed, was under the auspices of the Club, after the appointment of the judge had been made public, a member of the Committee wrote in the public papers to inquire by whose authority such appointment had been made, as he had not only not been consulted on the matter, but was altogether ignorant of any proceedings of the Club in connection with it.

A second point which requires clearing up is the statement of Mr. Tudman, that no judge was appointed; when, as it now appears, Mr. Hewitt had been engaged for the office. To say that the communication to that gentleman was a private one is no explanation of a statement which, as it now stands, is at direct issue with the fact. Besides, what possible objection could there be to the appointment being known? On the contrary, one would have thought that the interests of the Club would have been promoted by the fact of the Club having secured the services of that gentleman being made public. I am strongly impressed that the cause of Mr. Tudman's quarrel with you is not the publication of the circumstance of the appointment, but of the fact that the Club's rules for judging have broken down; showing as it does, that to secure the services of any one in whom the exhibitors have confidence, the rules they have elaborated have had to be sacrificed. But if the rules are to be suspended in Mr. Hewitt's case, under what arrangement are his colleagues to judge? and if the latter are to judge by the rules of the Society, how are their decisions to harmonise with his? Or, is Mr. Hewitt to judge certain classes only? If so, the exhibitors ought to know which those are.

In looking over the regulations, I find in No. 4 certain conditions prescribed according to which prizes are to be accorded. Can you inform me who are the parties who framed this rule? or whether it has emanated from the

Poultry Club? as the prize list is altogether silent on the subject.

I need not explain that no exception is intended in this communication to the appointment of Mr. Hewitt, of the value of whose services I am fully sensible, especially in connection with such a Show as the Islington one. Indeed, the absence of Mr. Hewitt as judge in an exhibition on so large a scale would destroy confidence in its success.

I have only to add, that if the three members of the Club selected for judges, of whom Mr. Tudman speaks as the most extensive breeders and successful exhibitors in the kingdom, are still in the practice of exhibiting, they are among the most objectionable parties to fill the office. In proof of this I need only instance the proceedings at the last Birmingham Show, a recurrence of which I should be very sorry to witness. In the present state of matters it would, perhaps, be most satisfactory to exhibitors who are not members of the Club, that the appointment of the judges to act with Mr. Hewitt in the forthcoming Show should be left in the hands of the Manager, he being a gentleman in whose experience and honour such exhibitors have the fullest confidence.—AN EXHIBITOR.

SUCCESSFUL POULTRY KEEPING.

I SEE many of your correspondents are complaining of want of success in chicken-rearing this season. I give the following as my experience:—

COCHIN.		
January 15th.—11	Hatched	7 Rared.
April 16th.—9	"	9 "
" 18th.—9	"	8 "
" 24th.—11	"	8 "
May 4th.—5	"	5 "
" 13th.—9	"	9 "
54	"	46 "
SPANISH.		
June 7th.—9	Hatched	9 Rared.
" 14th.—6	"	6 "
15	"	15 "

The first have been laying for just a month. The second and third average 4 lbs. 8 ozs. each. Perhaps you will tell me if that is not an excellent weight. [Certainly.]

I feed my adult fowls early in the morning (at this season 6 A.M.) on wheat, and twice afterwards on a mixture of 1 cwt. coarse oatmeal, 2 bushels of bran, and 1 sack of fine barley-meal, and find them thrive and lay gloriously. They have also lettuce *ad libitum*. — A COUNTRY POULTRY-KEEPER. Bridport.

THE POULTRY AT LINTON PARK.

THERE may be some among your readers who are not unwilling to hear a few words concerning Linton and its feathered inhabitants.

To begin. The park stands on a long hill side, the lower portion advancing into the valley, whilst the upper recedes over the plateau to the north. Soon after entering the gates a confused crowing—from what quarter it is not easy to say—strikes upon the ear, and on casting the eye around small shepherd-looking huts are seen at long distances apart. But before proceeding further we must make the acquaintance of John Martin, a taciturn man with an honest face, a curt manner, and a house and salary the envy of all the curates around. He is the guardian of Lady Holmedale's famous birds, and of his own counsels too; for if wrinkles there be in exhibiting, you might as well attempt to extract them from him as information from John Scott's confidential lad the night before the Derby.

Let us walk round with him, and a long walk it is; for about twenty bottomless huts, moveable on rollers, are scattered about the park near a few trees, the corner of a cover, or any such slight shelter, and each contains its independent colony. Here may be seen a score of lean-looking Spaniards foraging about; there a detachment of portly Dorkings; whilst high up on the bleak and windy hill top live a large family of Pencilled Hamburgs, clean active birds, wild as hawks, requiring all the blandishments of their keeper's voice and a liberal distribution of corn to

induce them to approach the unwelcome stranger. Nearer home some more Hamburgs reside, and a few maternal Cochins—fluffy tame domestic creatures, willing to make any one's acquaintance, and grateful for the smallest contribution.

But where are the poultry-houses, where her ladyship's pampered bipeds spend their lives in idleness and luxury? Where are the prize birds? "All about. He took first at Islington, Birmingham, Manchester. His brother choked himself last week after I had refused thirty-five sovereigns for him the week before that. He's worth forty," replies Martin, pointing to a monstrous cockerel with a briar-scratched comb and disordered plumage. True it was there running wild. One feed a-day, picking up a precarious existence on grass and insects, roosting in the trees or in their little draughty huts, with less care than the vilest barndoors, during the coldest nights of winter, live and thrive the Linton poultry. Nothing can look simpler than the process. The least possible deviation from a state of nature appears to a tyro the sole secret of success.

Nor is there much stress laid upon breeding from "cup" birds. Out of hundreds the trios are selected on which it is shrewdly surmised the experienced eyes of Messrs. Hewitt, Baily, and Co. will most love to dwell, and on them a brief season of care is bestowed, under which the rough-and-ready customers of the park and shrubbery improve into the sleek and ponderous champions we have so often seen, maintaining in the hour of trial the honour of the county of Kent.—A PULLET.

RIPON AND CLARO AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE fourth annual Meeting of this Society was held at Ripon, July 5th. Compared with last year, it exhibited a decided superiority in regard to quality.

GAME.—First, C. W. Brierley, Middleton, Manchester. Second, Miss E. Beldon, Bingley.

SPANISH.—First, Miss E. Beldon. Second, W. Elliot, Thirsk.

DORKING.—First, J. White, Northallerton. Second, Miss E. Beldon.

POLAND.—First, T. Heugh, Bedale. Second, Miss E. Beldon.

COCHIN-CHINA.—First, J. Bell, Thirsk. Second, C. W. Brierley.

HAMBURG (Golden-splangled).—First, Miss E. Beldon. Second, J. Walker, Knaresborough.

HAMBURG (Silver-splangled).—First, Miss E. Beldon. Second, C. Cowburn, Leeds.

HAMBURGH (Golden-pencilled).—First, Miss E. Beldon. Second, C. W. Brierley.

HAMBURGH (Silver-pencilled).—First, Miss E. Beldon. Second, W. R. Baynes, Bedale.

BANTAMS (Golden-laced).—First, Miss E. Beldon. Second, R. White, Ripon.

BANTAMS (Silver-laced).—First, C. W. Brierley. Second, Miss E. Beldon.

BANTAMS (Game).—First, J. Wade, Leeds. Second, Miss E. Beldon.

BANTAMS (Any other variety).—First, Miss E. Beldon. Second, J. Wade.

DUCKS.—First, C. W. Brierley. Second, J. Greaves, Clotherholme.

DUCKS (Aylesbury).—First, Miss E. Beldon. Second, J. G. Milner, Leyburn.

DUCKS (Rouen).—Prize, Miss E. Beldon.

DUCKS OF ANY BREED OR CROSS.—First, C. W. Brierley. Second, Miss E. Beldon.

EXTRA STOCK.—Prize, J. White, Northallerton.

PIGEONS.—Carriers (Any colour).—Prize, Miss E. Beldon. Tumblers (Almond).—Prize, Miss E. Beldon. Tumblers (Any other variety).—Prize, Miss E. Beldon. Pouters.—Prize, Miss E. Beldon. Runts.—Prize, J. Wade, Jacobins.—Prize, Miss E. Beldon. Fantails.—Prize, R. H. Walbran. Oolets.—Prize, W. Hughes, Leeds. Trumpeters.—Prize, Miss E. Beldon. Barbs.—Prize, Miss E. Beldon. Turbits.—Prize, Miss E. Beldon. Nuns.—Prize, Miss E. Beldon. Dragoons.—Prize, G. Sadler, Boroughbridge. Baldis or Beards.—Prize, Miss E. Beldon. Archangels.—Prize, Miss E. Beldon. Any New or Distinct Variety.—Prize, Miss E. Beldon.

Judges of Poultry:—Mr. H. C. Mason, Drighlington, Leeds; Mr. M. Hunter, Greenhamerton, York.

[We think this should be distinguished in the Society's Annals as "Emily Beldon's Year."]

ALEXANDRA PARK SHOW OF POULTRY, &c.—The entries for this Show, we are informed, will not close until Saturday, July 23rd, instead of the 16th.

IMPORTATION OF EGGS.—It is a startling fact, that in fourteen years the importation of eggs into this country has increased more than one hundred and sixty-nine millions. In 1849 there were imported 97,745,849, and in 1863, 266,929,680. The wholesale price in France is 6s. for ten dozen.

SNAITH AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE tenth annual Exhibition of the above Society was held on July 7th, in the spacious and beautiful grounds of Mrs. Shearburn.

The following were the prizes awarded:—

SPANISH.—First, W. Cannan, Bradford. Second, W. Houseman, Tadcaster. *Chickens.*—Prize, F. Powell, Knaresborough.

DORKINGS.—First, T. E. Kell, Wetherby. Second, T. B. Ireland, Tadcaster. *Chickens.*—Prize, T. E. Kell.

COCHIN-CHINA.—First, W. Cannan. Second, R. Dewes, Knaresborough. *Chickens.*—Prize, R. Dewes.

MALAY.—Prize, O. A. Young, Driffield. *Chickens.*—Prize, O. A. Young. *Game Cock.*—First, R. Bickers, Beverley. Second, T. B. Ireland. *Game Hens.*—First, J. Harrison, Holbeck. Second, T. B. Ireland. *Game Chickens.*—Prize, J. Barker, jun., Dunnington.

PHEASANTS (Golden).—First and Second, W. Cannan. *Chickens.*—Prize, C. Snowdon, Tockwith.

PHEASANTS (Silver).—First and Second, W. Cannan. *Chickens.*—Prize, W. Cannan.

HAMBURGS (Golden-pencilled).—First and Second, W. Cannan.

HAMBURGS (Silver-pencilled).—First and Second, W. Cannan.

CHITTERPAT OR CORSICAN.—Prize, W. Cannan.

POLANDS (Any variety, with or without ruffs).—First, W. Cannan. Second, O. A. Young.

ANY BREED OR CROSS.—First, F. Powell. Second, H. Lacy, Hebden Bridge. *Chickens.*—Prize, Mrs. Moore, Boston Spa.

BANTAMS.—First, T. E. Kell, Wetherby. Second, The Right Hon. Lady Londesborough.

COCK (Any Breed or Cross).—Prize, W. Cannan.

HENS (Any Breed or Cross).—Prize, T. E. Kell.

GEES.—First, O. A. Young. Second, W. K. Goodbarne, Tadcaster.

DUCKS (Any Breed except Aylesbury).—First, O. A. Young. Second, W. A. Park.

AYLESBURY.—First, W. Cannan. Second, O. A. Young.

TURKEYS.—First, W. Cannan. Second, Miss Walton, North Milford.

GUINEA FOWLS.—Prize, O. A. Young.

J. Richardson, Esq., of Thorne, officiated as Judge.

BELFAST POULTRY EXHIBITION.

(From a Correspondent.)

THE above Show came off on the 6th, 7th, and 8th of July, and our anticipations were fully realised. Amateurs supported the Exhibition in every way. All things were very comfortable, clean, and pleasant, there being plenty of light and air, and the pens were in a single row almost throughout. The Belfast market for butter and eggs is very extensive and covered in all round, and not a better place could be desired at this season of the year. This Society offer a £10 cup to be competed for by, and awarded to, the exhibitor most successful in gaining first prizes during three years. Mr. Beldon the great Yorkshire exhibitor, and Mr. Boyle, of Dublin, were competitors for this; and Mr. Beldon, who took ten first prizes, won the cup; Mr. Boyle gaining nine prizes. It must have been very instructive to other exhibitors to see such stock as shown here. Mr. R. Palmer Williams, and Mr. F. W. Zurhorst each showed very creditably.

Dorkings were the first on the list. There were eighteen pens and all very pretty. *Dorkings* were not good on the whole. The prize *Spanish* were far a-head of all others. *Cochins* were strong, and if we may speak our minds it was the only class in the Show in which a fault could be found in the judgment. It was the general opinion that the second prize should have been first, and a splendid pen of *Whites* second. A pen made up of *Partridge* and *Grouse* took first; the *Yorkshire* Judge had to give way to the faulty pen. *Brahmas* were very beautiful and formed a strong and attractive class. It is another of the curiosities of poultry and poultry showing that the *Hamburgs* are never good alike. As they were here, Mr. Beldon took the lead in all the classes; the Judges all agreed that there was not another pen in the Show, except the second-class *Golden-pencilled*, worthy of a second prize, but the Committee ordered all prizes to be awarded. *Game* were very poor except the first-prize *Black Reds*. *Polands* were strong but very poor except the first-prize pens. *Bantams* were very poor. Than the *Turkeys*, *Geese*, and *Ducks* shown by Mr. Boyle we do not expect to meet better. As will be seen by the prize list, he took all the first prizes.

DORKING.—First and Third, Col. Leslie, M.P., Castle Leslie, Glasslough, Second, R. P. Williams, Glaslin, Fairview, Co. Dublin. *Chickens.*—First and Second, R. P. Williams, Glaslin, Fairview. Third, Col. Leslie, M.P.

SPANISH.—First, H. Beldon, Gilstead, Bingley, Yorkshire. Second, G. Martin, Glenview, Belfast. Third, R. W. Boyle, Rosemount, Dundrum,

Co. Dublin. Commended, R. P. Williams. *Chickens.*—First and Second, R. W. Boyle, Rosemount, Dundrum. Third, C. E. M'Clintock, Millmount, Randalstown,

COCHIN-CHINA.—First, F. H. Lewis, Nettlefield, Belfast. Second, H. Beldon. Third, F. W. Zurhorst, Belville, Donnybrook, Dublin. Highly Commended, F. Langtry, Malahide; F. W. Zurhorst.

BRAHMA POOTEA.—First and Second, R. W. Boyle. Third, F. W. Zurhorst.

SCOTCH GREYS.—Prize, G. Martin, Glenview, Belfast.

HAMBURG (Silver-spangled).—First, H. Beldon. Second, R. P. Williams. Third, F. H. Lewis.

HAMBURG (Silver-pencilled).—First, H. Beldon. Second and Third, F. H. Lewis.

HAMBURG (Golden-spangled).—First, H. Beldon. Second, J. Montgomery, Wolfhill, Belfast. Third, G. Martin, Glenview, Belfast.

HAMBURG (Golden-pencilled).—First, H. Beldon. Second, R. W. Boyle. Third, F. H. Lewis.

GAME.—First, G. Langtry (*Black Reds*). Second and Third, F. H. Lewis.

BANTAMS (Game).—First and Second, F. H. Lewis. Commended, F. H. Lewis.

BANTAMS (Any other Breed).—First, R. Niven, jun., Chrome Hill, Lisburn (*Sebright Bantams*). Second, J. Wilson, Carrickfergus (*Sebright Bantams*).

SINGLE COCKS.

DORKING.—First, F. H. Lewis, Nettlefield, Belfast. Second, Col. Leslie, M.P., Castle Leslie, Glasslough. Commended, Lord Lurgan, Brownlough House, Lurgan.

SPANISH (Black).—First, H. Beldon, Gilstead, Bingley, Yorkshire. Second, C. E. M'Clintock, Millmount, Randalstown.

HENS.

DORKING.—First, Col. Leslie, M.P., Castle Leslie, Glasslough. Second, R. W. Boyle, Rosemount, Dundrum, Co. Dublin. Highly Commended, G. Langtry, Montague House, Malahide. Commended, F. H. Lewis, Nettlefield, Belfast.

SPANISH (Black).—First, H. Beldon, Gilstead, Bingley, Yorkshire. Second, E. M'Clintock, Millmount, Randalstown.

COCHIN-CHINA.—First, F. W. Zurhorst, Belville, Donnybrook, Dublin. Second, F. H. Lewis.

BRAHMA POOTEA.—First, R. W. Boyle. Second, F. H. Lewis.

FOWL WITH CRESTS.

POLAND (White-crested Black).—First, H. Beldon. Second, F. H. Lewis. Third, G. Martin, Glenview, Belfast.

POLAND (Silver-crested Spangled).—First, H. Beldon. Second and Third, F. H. Lewis.

POLAND (Golden-crested Spangled).—First, H. Beldon. Second and Third, F. H. Lewis. Highly Commended, R. P. Williams. Commended, G. Martin.

EXTRA STOCK.

BANTAMS (Gold-laced).—Prize, R. Niven, jun., Chrome Hill, Lisburn.

TURKEYS.—First, R. W. Boyle, Rosemount, Dundrum. Second, R. Mehaffy, Clontenacally, Newtownbreda. (*Good*.)

GEES.—First, R. W. Boyle. Second, H. L. Prentice, Caledon (White). Third, R. W. Boyle. (*Out of feather*.)

DUCKS (Aylesbury).—First, R. W. Boyle. Second, R. P. Williams. *Ducklings.*—First, R. W. Boyle. Second, R. P. Williams. Third, W. Charley, Seymour Hill, Dunmurry.

Ducks (Rouen).—First, R. W. Boyle. Second, H. L. Prentice, Caledon. Third, R. P. Williams. Highly Commended, J. Montgomery, Wolfhill, Belfast. Commended, G. Martin, Glenview, Belfast. *Ducklings.*—First, R. W. Boyle. Second, G. Martin, Glenview, Belfast. Third, J. Wilson, Carrickfergus.

The following gentlemen were the Judges:—Mr. John Crosland, jun., Mr. Patterson, and Mr. Williams.

MORTALITY AMONG CHICKENS.

LIKE “A. K. C.” I considered myself no novice in poultry-rearing, and like him I have had my disappointments and vexations in rearing chickens. Although I well knew how to rear them for the table and stock, and had learnt to my cost that over-feeding and filth were the great and immediate plague to poultry, yet notwithstanding all my knowledge, how puzzled and vexed was I with my chickens dying in the very same manner your correspondent describes after every stimulant had been offered.

Without entering into details, I concluded that the cold had something to do with it. I immediately erected a shed well closed in, with a glass window, close to the ground, looking south, and put all the necessaries of chicken life therein. The floor I spread with clean dry straw about 1 foot deep, and then placed my chickens in this shed.

The result was that they gave up dwindling, and were soon healthy chickens. The dry straw and a few grains of wheat scattered throughout were the best preservatives to chickens that had come under the notice of—**A LANARKSHIRE BEE-KEEPER.**

I may also state that I found it easier to rear chickens in the early spring months than in May, June, or July. The dewy mornings then proved always fatal.

NEW VARIETIES OF PIGEONS.—I am very much obliged to your Bingley correspondent for his description of “Brun-

wicks" and "Satinettes." His opinion quite agrees with mine—namely, that the Brunswicks are only one of the varieties of Priest Pigeons, and the Satinettes are a spangled-shouldered variety of Turbits. I do not know anything of the green Pigeons described by Dr. Livingstone, but no doubt they are a distinct species from the domestic Pigeon.—B. P. BRENT.

GOOSE BREEDING.

As Geese are long-lived, so they are long in reaching maturity, not becoming good for breeding purposes before they are from three to five years of age. The third or fourth year is as early as is desirable to mate Geese for this purpose. Then having selected the best of their kind, one gander to no more than two Geese (and some males will only mate with one female), and the gander not related to the Geese, the breeder may consider that he is supplied with a good breeding stock for at least the next twenty years, or, as one writer says, "for life."

In confirmation of this statement, Mr. S. Jaques, jun., of Boston, Massachusetts, wrote, in 1850, of a Bremen Goose that his father imported in 1821: "She has never failed to lay from twelve to sixteen eggs every year for the last twenty-seven years, and has always been an excellent breeder and nurse, as has all the stock and offspring connected with her. I had the curiosity to weigh one of her brood in 1849, when nine months old exactly, and his weight in feather sent up 22 lbs. in the opposite scale." The earlier the goslings are hatched in spring the better, and there is no agent so good for this purpose as the Goose, though the Ducks do very well. Hens appear to have too dry a heat for the purpose, and though a part of the eggs may hatch, the goslings are not as strong as those hatched by the Goose or a Duck. For the first twenty-four hours after hatching, like chickens, the young require no feeding. On the second day they will begin to nibble a little fine grass, or young clover, from a fresh sod placed near the nest. They will also want a little scalded corn meal or oatmeal, or a few bread crumbs, and a shallow vessel of water. If the weather is fine, it will soon do to "turn them out to grass," but they should be housed every night and during stormy weather, on a dry floor, until several weeks old; and the better the young are fed for the rest of the season, the larger and better the fall goslings. Wheat bran or the best class of "shorts" mixed with boiled potatoes makes a good feed for goslings after a few weeks old.—(U.S. Agricultural Report.)

POULTRY, PIGEON, RABBIT, AND CANARY LORE.

I SHOULD be very pleased if Poultry, Pigeon, Rabbit, and Canary fanciers would follow the example set in THE JOURNAL OF HORTICULTURE by the bee-keepers, and interchange in its pages their experiments and experiences. Poultry lore seems now reduced to an account of the prize lists of some of the shows, or an occasional cry from some despairing Brahma fancier; still less is now written on Pigeons, while Rabbits and Canaries are quite forgotten. I am very desirous of seeing more communications on these subjects, and willing to do what I can in the cause.—B. P. BRENT.

[Our wish is an echo of Mr. Brent's. Our columns are open to the fanciers of all the pets enumerated by him, and we wish that one and all would communicate their modes of management, observations on their merits, diseases, or other relative topics.—EDITOES.]

PRIDE IN FOWLS.—Fowls have plenty of vanity and pride. They are very sensible to admiration from man, and miss accustomed notice. The queen of the poultry-yard must eat first, and stand by the king at feeding time. She resists any invasion upon her rights, and will have a precedence in all things. Indeed, precedence in the court-yard seems as valued as at earthly courts. Age and priority of residence in the yard, not less than size and strength, constitute right to precedence. No dowager ever treated young chits of girls

more contemptuously than the senior hen treats her juniors. One has heard of a Swiss cow which died of vexation when her bell was taken from her. So did a hen of mine, long mistress of the poultry-yard, die of smothered pride, when a new queen-hen, partner to a new king (a pair I bought at a poultry show), came into my enclosure. The rival queens eyed each other for a moment steadfastly, then rushed to the combat. The new comer, though the old hen fought bravely, was the stronger. Mrs. Mercury, as we called the old hen, from the wing-like feathering on her legs, never attempted to try her chance again, succumbed in a melancholy manner, and after a few days' moping gave up the ghost.—(*All the Year Round.*)

[NOTE BY ED. C. F.—The above is no fiction. We had a beautiful Bantam cock, which died of mortified pride. A Black Spanish cock was uncooped in the same yard in which the Bantam was strutting about, when the latter attacked the new comer with beak and nail. The Spaniard treated the little fellow with cool contempt, and from that moment the Bantam pined, drooped, refused food, and at length died.]—(*Canada Farmer.*)

ANTWERP PIGEONS.

IN accordance with the request of "PARVO" I will endeavour to describe the properties of the various breeds of Pigeons known as "Antwerp Carriers."

The inhabitants of Belgium have long been famous for Pigeon-flying, and consequently we find among them several very superior strains of homing birds. The basis of these breeds, it would appear, was a cross between the Dovehouse Pigeons, or Rocks, and Tumblers. Such birds, known as Volans and Voyageurs, are common on the continent, and are esteemed for their high flying. Such Pigeons having strayed or been lost have taken themselves to the lofty towers and steeples of the churches, &c., in the larger towns, where they have had for ages to take care of themselves, and run the gauntlet against all sportsmen and birds of prey, which are tolerably numerous; and it is easy to understand that the remnant of such a breed would be pre-eminent as homing birds, and such, I am informed, is the origin of the real Antwerp Carrier Pigeon. I can only describe the breed as a small mealy Rock, which colour greatly predominates among the Dovehouse Pigeons thereabouts.

The true Antwerp is in shape much like a Rock or Dovehouse Pigeon, but rather slighter built, bolting eye, and clean sharp-looking head.

Many other kinds are bred; for instance, about Liège the Owl form predominates. The Smerles, as they are there called, are very much like an Owl Pigeon, their colours being mealy, red or blue chequered, and sometimes blue. This breed is even more widely diffused than the Antwerp. Their powers of flight are extraordinary; and, from some accounts of Pigeon-flying, I have computed that they home at the rate of forty-seven miles an hour. I do not know that there are any very particular points of outward appearance, but their homing faculty is their main recommendation. These Smerles have been crossed with the English Dragoon, and have produced a stronger and stouter bird.

I have also heard of Blue Pigeons, with feathered feet, of excellent homing qualities, brought from Antwerp; and, doubtless, in a country so famous for flying Pigeon races, there are many choice strains that are little known except to their proprietors, particulars of which I am quite unable to give.—B. P. BRENT.

BEES IN LINCOLNSHIRE.

AS I some time ago troubled you with a chapter of lamentations, it is but fair that I should let you know something of my better success. The season in this neighbourhood has been a most wretched one so far as multiplication by natural swarming is concerned, though a good one for honey-harvesting. Few bee-keepers have had more than about one swarm from every six hives which they possessed, and very many have had none at all. My last autumn and winter's disasters left

me with just two hives in good condition—a Nutt's collateral that has stood three years, and a common cottage-hive that has stood four years. I had intended to get a couple of first swarms naturally from them, and then to unite the old stocks into bar-frame hives, as I intend to use none others in future. The bad season for swarming, however, quite frustrated this intention. They hung out till I was tired of watching them, and resolved to get artificial swarms by driving and transposing. The result has surpassed my most sanguine expectations, and not only are the driven swarms first-rate (of course I allowed a fortnight's interval after driving the one before operating similarly on the other), but the stocks are also in prime condition. I only regret that I did not adopt this course a month earlier than I did. After driving the first, the old stock in its transposed condition hung out strongly the day afterwards. Of course, it has since been used only for transposition.

My friend "E. B." very kindly sent me a Ligurian queen a short time since, and which I successfully placed at the head of a stock by a process which I have never seen described, and, therefore, to me quite original. The said queen arrived just after driving and transposing my two stocks; and as I was unwilling to interfere with either of them or the swarm so soon, if I could avoid it, I made an arrangement with a bee-keeper in the neighbourhood for one of his stocks, which had been hanging out for some time. Having a bar-hive untenanted that was two-thirds filled with healthy comb and a considerable quantity of honey, I transposed it with the stock at about 11 A.M. when fully at work. The returning bees of course entered it, and a state of great excitement naturally ensued. In an hour I placed a box over the top, containing the Ligurian queen and about a couple of dozen of her subjects, the box having a moveable top of glass, and a moveable bottom of perforated zinc. The excitement slightly abated on this being done, and I left her so till 3 P.M., when I took her own subjects away, and then allowed one bee to enter from below. Perceiving that it behaved most affectionately to her (if it had not, its death warrant had been sealed instanter), I admitted a few more, one at a time; and finding that they all appeared doubly affectionate, at last I withdrew the slide altogether, and allowed them all to descend. Work recommended vigorously at once, and plenty of bees from the old stock joined them during the succeeding two days, and the result is a fine swarm headed by a Ligurian queen.

There is an old proverb that "It never rains but it pours;" for, on the very day that this queen arrived, a beautiful Ligurian swarm, with queen born in Italy, arrived through the kindness of a relative who is, however, not himself a practical apriarian. It was on arrival transferred into a bar-frame hive and is doing remarkably well; so you see that being quite free again from foul brood I am once more in a favourable condition.—G. F. B., Spalding.

EXTRAORDINARY LIGURIAN SWARMS.

I WONDER whether I shall astonish you as I have done all about here when I tell you that the eight-pound swarm of mine in May (Ligurian), cast again for the third time on Wednesday, July 5. On the previous Saturday the bees flew out as though swarming, and on examination I found a dead queen; yet on Wednesday they swarmed in spite of a super. The grandmother on examination proving to have no queen, I have joined this one to her, otherwise I should have liked to have kept for a curiosity a third virgin swarm.

—A NORTHUMBERLAND BEE-KEEPER.

[The fecundity of this monster Ligurian swarm has evidently been quite on a par with its unprecedented magnitude.]

LIGURIANS IN AYRSHIRE.

My Ligurian hive having thrown a very fine swarm yesterday (10th July), a thing far beyond my expectation two weeks ago, I must pronounce Liguriants superior to blacks in multiplication. I can now see no means of getting the young queens impregnated with Ligurian drones, but will

carry my after-swarms to the country, where they will be a reasonable distance from blacks.—A STEWARTON APIARIAN.

[The old stock should, of course, accompany the after-swarms in their country excursion; nor should the first swarm be left behind if it contain drones, as is probably the case.]

COOKING MEATS.—Every wife and mother owes it to herself, her husband, and her children, as well as to society at large, to prevent waste in every department of the household, whether provisions are cheap or dear, whether the husband is rich or poor: for waste is a crime against humanity, an insult to the bounteous Hand which "giveth us all things, riches to enjoy." On the other hand, a true economy is one of the wisest, the best, and ennobling of domestic virtues. A hundred careful experiments were made in England in reference to roasting and boiling meats in order to ascertain the respective losses. Roasted chickens lost 15 per cent.; beef ribs and sirloins, 19 per cent.; geese, 19 per cent.; boiled mutton legs, 10 per cent.; boiled beef, 15 per cent.; boiled shoulder of mutton, 28 per cent.; turkeys lost 20 per cent.; mutton legs and shoulders, 24 per cent.; ducks, 27 per cent. Boiling beef saves more than 4 per cent. over roasting. If a leg of mutton is boiled it loses 10 per cent.; if roasted, 25 per cent.? The fatter meat is the greater the loss; it should be moderately fat to make it tender; but there is an unprofitable fatness. Eleven pounds of roast beef rib lose 2 lbs. and the bones 1 lb., so that of 11 lbs. bought only 7 lbs. come to the table. Hence if roast rib pieces cost in New York, in April, 1864, 20 cents a-pound at the butcher's stall, it is more than 31 cents a-pound on the dinner-table. It is philosophically true that 1 lb. of clear roast beef is more concentrated than 1 lb. of boiled beef, has less water in it, and hence may contain more nourishment; but the more concentrated food is, the more unwholesome it is, not only because it requires a greater digestive power to convert it into pure blood, but the sense of sufficiency at meals is induced to a considerable extent by the bulk of what is taken, and if we eat concentrated food until there is bulk enough to remove the feeling of hunger, there is so much nutriment in it that nature can't extract it all in a perfect manner; hence there is not only too much nutriment for the wants of the system, but all of it is imperfectly prepared and we really get less of the strength and less pure blood out of it, than if much less had been eaten, or it had been taken in a more bulky, or, if you please, in a more watery condition. This is the reason why dyspeptics and others eat a great deal, but they do not get strong. But if there is too much bulk, there is not enough nutriment although a great deal is taken into the stomach. Porter and beer, for example, fill up the stomach, and seem to make persons fleshy, but there is little nutriment and great bulk; great beer-drinkers are never strong but are puffy.—(Hall's Journal of Health.)

OUR LETTER BOX.

SUPERIORITY OF THE LIGURIAN BEE (*A. K. C., Dunsley*).—This new species is unquestionably far superior in fecundity, good temper, and beauty to the common bee-hive.

LIGURIAN BEES—**A WINDOW APIARY** (*M. B., Hampton*).—Writs to T. Woodbury, Esq., Mount Radford, Exeter. Bees will very probably do well in an upper room, but we do not think it possible to avoid the occasional loss of swarms from such a situation.

MAIDEN SWARMS (*H. P., North Lincolnshire*).—Two swarms from a swarm of the current year are unusual but not unprecedented.

UNITING WEAK STOCKS (*A Constant Subscriber*).—Blow a little smoke into each, and after allowing them two or three minutes to enable the bees to fill themselves with honey, invert one hive in a pail, and surmount it with the other, then drive the inhabitants of the lower hive into the upper one, and the union will be complete. This operation should be performed in the daytime, and, if adroitly managed, need not occupy many minutes.

TRANSFERRING BEES (*A Constant Reader*).—Although more than one swarm may generally be looked for, the rule is by no means invariable. If you mean to break up the stock it should be done in the autumn when the honey harvest is over, and little brood exists. Any attempt to transfer the bees to a Payne's-hive at this time would probably end in their entire destruction. Comb-building in an upward direction is not at all unusual.

BUTTER IMPORTED AND EXPORTED (*Essex*).—Last year 986,708 cwts. were imported, and 102,406 cwts. exported.

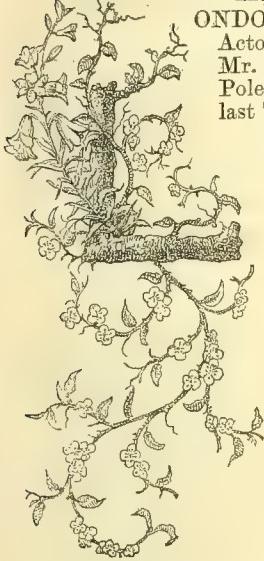

WEEKLY CALENDAR.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 75.1°, and its night temperature 51.1°. The greatest heat was 82° on the 26th, 1862; and the lowest cold, 36°, on the 1st, 1862. The greatest fall of rain was 1.39 inch.

A FEW SHOW GOOSEBERRIES.

RED KINDS.

ONDON, raised by Mr. Wilcock, of Acton, Cheshire, and sent out by Mr. John Banks, jun., at the May Pole Inn, Acton, Cheshire, on the last Tuesday in October, 1831, is at the present time the largest red Gooseberry in general cultivation, and has obtained a greater number of first-class prizes than any other kind. Mr. John Flower, of Stoke-by-Stone, Staffordshire, exhibited of this variety at Lower Tean, near Cheadle, Staffordshire, on the 7th of August, 1852, the largest Gooseberry on record—viz., 37 dwts. 7 grains. This variety grows in various forms. The three-veined berries, well managed, will grow from $1\frac{1}{2}$ inch to $2\frac{1}{2}$ inches in length, and from 5 inches to $5\frac{1}{2}$ in circumference. The long ones are generally the best in form,

and are very nearly the same in girth the whole length of the berry, tapering slightly towards the top, which is rather flat and ridgy, with the seed veins lower than the rest of the surface, which gives the ridged shoulders; but the ridges do not extend far from the top, the berry terminating with a round prominent nose. The two-veined berries are similar in form, except that they are flat-sided and often a little longer. The shorter ones are often deficient of seed, more ridgy, and deformed. In colour London is very dark red, almost chocolate, the berry perfectly smooth; flavour tolerable, but not first-class. It makes a spreading bush; the wood is almost smooth, producing but few thorns, and does not do well until the plants are strong. An uncertain cropper, but when caught sound will excel any other kind.

YOUNG WONDERFUL, or WONDERFUL, as now called, was raised by Mr. James Sanders, of Marston, Cheshire, and sent out by him at the Crown Inn, Peover, near Knutsford, Cheshire, on the fourth Saturday in October, 1829. This variety was the heaviest berry grown for the following years—viz., in 1832 it was equal with Lion, both being 27 dwts. 13 grains; in 1833, 27 dwts. 17 grs.; in 1834, 27 dwts. 8 grs.; in 1835, 24 dwts.; in 1838, 30 dwts. 16 grs.; in 1841, 32 dwts. 16 grs. This variety is similar in form to London, but shorter, and eight or ten days earlier. It colours better to the top; the skin has a softer appearance, and is strewed with brownish specks. The colour is darker than that of London, and the berry, not so much ridged, is perfectly smooth. Habit of growth upright, short-jointed, with thick shining leaves and short prickles. It breaks early in spring, and is but a shy cropper in some districts. Flavour good.

COMPANION, raised by Mr. William Hopley, of Wistaston, Cheshire, from a Gooseberry grown by Mr. John Bratherton, of the same place, was sent out by Mr. Hopley, at the Rockwood Inn, Wistaston, Cheshire, on the last Monday in October, 1829. This variety is a general favourite, both as a show kind and for general cropping purposes. In 1836 it was the heaviest berry exhibited of any colour—viz., 28 dwts., and again in 1837, one of the smallest seasons recorded, it was the heaviest grown—23 dwts. 12 grains. Since that time London has taken the lead, except in the years 1838, 1841, 1859, 1862, and 1863. In 1842 Companion was 31 dwts. 5 grains; in 1852 it was 31 dwts. 11 grains. It is a bright light red, very rough, generally two-veined, but plump in form, with one shoulder a little higher than the other, rather square at the top, the nose nicely rounded to the snuff; flavour very fine; ripens well to the top, with nice supple skin; rather early. It makes a fine spreading bush, and is a most prolific bearer, the fruit being much the same size all over the tree.

That fine variety *Antagonist* is a seedling raised from Companion, and turns out to be the largest white berry, and, to all appearance, is likely to be the largest of any colour.

ROARING LION, or LION, as it is now called, was raised by Mr. Reuben Farrar, and sent out by him at the Eagle and Child, Whitefield, Lancashire, on the third Saturday in October, 1818, and for some years was the heaviest berry grown of any colour. In 1825, the heaviest berry weighed 31 dwts. 16 grains; in 1828, 29 dwts.; in 1829, 25 dwts.; in 1831, 27 dwts. 6 grains. It is a very long berry, from $1\frac{1}{2}$ to 2 inches long; the three-veined ones are finely formed, but not so ridgy as the London. The two-veined berries are long and rounder than the two-veined Londons. The skin is hard-looking, perfectly smooth, of a deep red colour, the veins of a brownish hue; the stalks are very long and rather fine for the size of the fruit, being much smaller than the stalks of the London. It makes a fine-spreading bush; the wood rather fine, and weeping a little towards the end of the shoots; very vigorous. Flavour not fine.

YELLOW KINDS.

LEADER was raised by Mr. William Piggott, of Moreton, Cheshire, and sent out by him at the Wolf's Head, Congleton, Cheshire, on the last day of October, 1826. This is, in every respect, a first-class variety, and has many times been the heaviest yellow berry shown for the season—viz., in 1829 it weighed 23 dwts. 14 grains; in 1831, 26 dwts. 17 grs.; in 1832, 26 dwts. 9 grs.; in 1835, 23 dwts. 12 grs.; in 1837, 22 dwts.; 1838, 26 dwts. 5 grs.; in 1841, 27 dwts.; in 1842, 25 dwts. 10 grs.; in 1843, 28 dwts. 14 grs.; in 1844, 27 dwts. 21 grs.; in 1847, 27 dwts.; in 1856, 24 dwts. 12 grs. I have only named the weight for the years it was the heaviest of its colour. There are few that can excel it at present. This is a plump well-formed berry with fine shoulders, which are prominent. The three-veined berries are very round, the seed veins lower than the rest of the surface; the two-veined ones rather flat-sided, but round-off nicely to the

nose. It has a beautiful soft-looking skin, with a bloom similar to a peach; colour dull muddled yellow; flavour of the finest quality. Makes a fine vigorous bush, growth upright; and a most prolific bearer.

YELLOW GUNNER was sent out by Mr. Hardcastle about the year 1821, and, I believe, it is of Lancashire origin, but I am not certain as to when and where sent out. It is one of the best old varieties, and was the heaviest yellow berry shown in the following years—viz., in 1826, when it weighed 23 dwts. 4 grains; in 1827, 27 dwts. 1 gr.; 1828, 24 dwts. 5 grs.; in 1833, 25 dwts. 2 grs.; in 1834, 23 dwts. 11 grs. The berry is very round, handsomely formed, and covered with strong rough spines; it is one of the roughest berries grown. In colour it is almost olive green, shaded and blended with a yellow tinge, the veins a little lighter than the rest of the skin. It ripens well, and is of fine flavour. Habit of growth strong and robust, making a fine upright bush.

GOLDEN SOVEREIGN was raised by Mr. John Bratherton, of Wistaston, Cheshire, and sent out by him on the last Monday in October, 1821, at the Rockwood Inn, Wistaston, Cheshire. This was a useful variety for some years, but has long since been surpassed as a show variety. It is of a bright light yellow, of medium length, ripens early, is a free bearer, and of good flavour.

GREEN KINDS.

BUMPER was raised by Mr. John Bratherton, of Wistaston, and sent out by him at the Rockwood Inn, Wistaston, Cheshire, on the fourth Monday in October, 1832. This variety was shown as a seedling, and has weighed 30 dwts. 18 grains; but was soon eclipsed by Thumper, sent out by Mr. Richard Ryle, of Wistaston, on the same day. Bumper is light green, smooth, of medium length; an early variety, ripens too soon at the nose, and is very subject to shanking in hot weather. Habit rather weak and spreading. At the present day it is useless.

TRROUBLE is a long berry, tapering very much towards the stalk. It is rough, and in colour very dark green. Quite useless at the present time for any purpose.

WHITE KINDS.

EAGLE OF THE SUN, now called **EAGLE**, was raised by Mr. Thomas Cook of Hatherlow, and sent out by him at the Spread Eagle, Hatherlow, Cheshire, on the 1st of November, 1823; and in 1825 it was the heaviest white berry exhibited—viz., 23 dwts. 20 grains; and it weighed as follows—in 1827, 24 dwts. 18 grains; in 1830, 27 dwts. 12 grs.; in 1831, 25 dwts. 18 grs.; in 1833, 23 dwts. 11 grs.; in 1834, 25 dwts. 22 grs.; in 1835, 21 dwts.; in 1840, 24 dwts. 9 grs.; in 1844, 26 dwts.

It is one of the longest berries grown. The three-veined berries are very fine in form, long, smooth, and very round. The two-veined berries are rather flat, and generally a little tapering towards the stalk, which is rather long and small. Colour yellowish white. Makes a fine bush. Wood long and rather fine; bears freely; flavour tolerable.

OSTRICH was raised in the neighbourhood of Wistaston by Mr. James Billington, was sent out by him on the last Monday in October, 1827, and was the heaviest white berry exhibited in 1829, 21 dwts. 11 grains; in 1832, 24 dwts. 20 grains. This variety is very long, rather flat on the side, and seeds badly, consequently seldom weighs well for the size of the fruit. It is a little rough, colour yellowish white; in habit it grows freely, makes a fine spreading bush, and bears well.

WHITE SWAN was raised by Mr. William Wood, and sent out by him at the Grapes Inn, Croston, near Chorley, Lancashire, on the third Monday in October, 1831; and was the heaviest white berry grown in 1838—viz., 24 dwts. 16 grains. The berry is of medium length, very smooth, of a darkish white colour; the veins very conspicuous, being broad and much whiter than the rest of the berry. It makes a fine bush, and bears freely.

It will be seen by the above that very few of the better kinds of show Gooseberries are of Lancashire origin, although so often called "Lancashire Show Gooseberries."—C. LEICESTER.

ROYAL HORTICULTURAL SOCIETY'S GARDEN.—In compliance with a wish expressed by Her Majesty the Queen, the

Council have announced that on the 26th of August next, the late Prince Consort's birthday, the public will be admitted gratuitously to the Society's Gardens at Kensington, and that the same tribute to his memory will be continued in after years.

ORCHARD-HOUSE PRODUCE—DESTROYING APHIDES.

FROM an orchard-house, heated in cold weather, in five days last week eighty dozen of Peaches and Nectarines have been gathered for market, besides many not fit, but used at home. 18s. per dozen was the largest sum received for Nectarines this season. There are Vines in this house, but kept exposed until the middle of April, the crop from these is very large. My gardener made £164 for his Grapes this season from one house 110 feet by 15; the roots were covered with glass also to the extent of 5 feet in addition to the 15. He began cutting in the middle of April, when he sold the Grapes for 12s. per lb.

I find the best remedy for aphides out of doors is 1 lb. of perfectly dry Scotch snuff and 3 lbs. of the white silicious dust which can now be obtained quite dry in any quantity in our lanes; being silicious, every particle can be syringed off. A puff-ball of indiarubber with a conical tube is the best thing for small growers to apply this with; a saucer being used for the powder, the ball when empty and compressed will suck up the powder. Yesterday, the 19th inst., the whole atmosphere in this neighbourhood was loaded all day with green fly.—AMATEUR.

LA CONSTANTE STRAWBERRY.

MAY I be allowed to recommend such of your readers as contemplate making new Strawberry-beds to try La Constante? I grow Filbert Pine, British Queen, Crimson Queen, Carolina Superba, and many others, but I do not think one of them is equal to this very fine variety. There is a peculiarly delicious aroma about it which no other Strawberry possesses, and it is a handsome-looking fruit and ripens thoroughly where British Queen will not.—P.

[We quite agree with our correspondent in his praise of this most excellent variety.]

GISHURST COMPOUND VERSUS AMERICAN BLIGHT.

WE have had a very bad year for the American blight on our Apple trees, so much so that we have been applying the Gishurst with the garden engine, and in doing so I noticed a fact that may interest you—viz., that all the trees that had been dressed with Gishurst in previous seasons were clean, or nearly so, while those that for ten years had never been blighted, nor dressed, were this year covered as with snow. The spread this season is beyond anything I have ever known; it is a hard matter to find a clean tree, but I am determined, if possible, to keep it down. My success with the Orange family has been complete. Three dressings in two weeks in the spring, with a solution not stronger than 2 ozs. to the gallon, will carry the trees through the summer clean. We do this when the fruit is gathered, and before the growth starts for the following season, and have no further trouble with them.—JOHN CARSON, Melbourne, Australia.

CULTIVATION OF THE MELON.

(Continued from page 43.)

SUCCESSION.—To have a regular supply of Melons, it is necessary to have a succession of beds. Subjoined is a table of the principal operations, and the times of their performance, on a number of beds and pits heated by dung alone, which furnished a regular supply of Melons of fine flavour from May to November. The time of setting was when the fruit began to swell freely.

							Total.....	241	...	74		

The above table refers to a place where the supply of fresh litter was equal to a cartload of dung per day, and the demands of the family great. For a moderate family three frames or pits are sufficient to afford a fair amount of fruit from June, or the beginning of July, until the middle of October.

The following table gives the dates of the principal operations in three such pits, with the heat at 1 foot below the surface, also the day and night temperature at various stages:—

First crop, also furnishing a second crop.—Sorts: Orion, Scarlet Gem, and Early Cantaloupe.

	Sown.	Bed Made.	Bed Soiled.	Bed Planted.	Bed Earthed.	Fruit Set.	Fruit Ripe.
Date	Feb. 6.	Mar. 5.	Mar. 15.	Mar. 21.	April 24.	May 14.	July 10
Soil	85°	...	91°	88°	86°	84°	81°
Day temp....	85°	...	84°	81°	85°	85°	85°
Night temp.	70°	...	73°	70°	65°	67°	71°

Second bed or succession.—Sorts: Bromham Hall, Beechwood, Bousie's Incomparable.

Date	Mar. 3.	Mar. 27.	April 14	April 21	May 17.	June 20	Au. 15
Soil heat ...	87°	...	88°	84°	82°	85°	83°
Day temp....	85°	...	87°	85°	82°	86°	84°
Night temp.	68°	...	71°	67°	64°	71°	70°

Last crop.—Sorts: Egyptian, Stoke Farm, Excelsior.

Date	April 6.	April 26	April 30	May 10.	June 7.	July 18.	Sep. 15.
Soil heat ...	84°	...	97°	88°	84°	81°	76°
Day temp....	87°	...	88°	86°	85°	85°	85°
Night temp.	70°	...	74°	67°	65°	63°	62°

SUPPLY.—A range of pits of nine lights, divided into three compartments, each 11 feet by 6 feet, or separate frames, will furnish on an average fifty fruits of good size and flavour, some years more, others less. Two fruits are sufficient for a strong, healthy plant to bring to maturity; more are had at the expense of size and flavour. Where, however, two plants only are placed under one light, three fruits may be taken from one plant, and where a quantity of Melons are desired, size being no object, more may, of course, be left on a plant. In 1861, I cut thirty-seven fruit from nine plants in a three-light pit in July, and in September seventeen more, making a total of fifty-four, the fruit weighing col-

* After the fruit was cut the old vines were pruned in to near the root as the young shoots springing from the stem, or near it, determined. These shoots were encouraged when the fruit approached ripening, or became netted. A portion of the old soil was removed, and its place supplied with fresh. Water was supplied copiously, and a fresh lining of hot dung applied. By these means a healthy action of the roots was encouraged, and the result was a crop of fruit little, if at all, inferior to the first.

lectively 41 lbs.; whilst from nine plants in an adjoining pit of like dimensions, seventeen fruits were cut, which weighed 33 lbs., or, on the average, double the weight of those produced by plants carrying a greater number of fruit.

Where the supply of fermenting material is only sufficient to make up a bed, it is useless to attempt to obtain a crop of Melons early, unless hot dung be in readiness to renew the heat by linings; then a crop may be relied on. With only sufficient dung to form a bed, it is best to defer making it up until the middle of May, so as to have it in proper order for the reception of the plants, which may be procured of some gentleman's gardener; or a few pots of the desired kinds might be accommodated in a neighbour's frame to forward, and have them ready to plant in the bed when it is ready to receive them; if not, a small frame must be placed on a hotbed, that the plants may be forwarded in it. If a Cucumber-frame at work be at command, no difficulty will be experienced in raising plants. A bed made up early in May, 3 feet or more in height, and a foot wider than the frame, will retain a moderate heat for about six weeks, by which time the heat of summer will be almost sufficient to carry on the plants without artificial heat; but if wet, dull weather set in, particularly at the time when the flowers are on the point of setting, the short grass coming from lawns after mowing, placed round the frame on the dung, will revive the heat, and materially aid the process of fecundation. In dull, cold seasons, it is next to impossible to get Melons to set their fruit where there is not material at hand for lining the bed; but in the majority of seasons fruit of moderate size and flavour may be had by aiding the plants at the beginning with a little warmth, and then husbanding the sun heat.

FERMENTING MATERIALS FOR HOTBED.—Where the inclination exists to have anything, means are easily provided, not that everything will do for supplying heat to Melons, but the most simple and common materials of a fermenting character may advantageously be employed. Tree leaves may be collected in the autumn when dry, and kept in any out-of-the-way place, piled up or closely packed together so as to represent a stack, with a ridge roof thatched with coarse grass, reeds, or straw, which will throw off much of the wet, and keep the leaves nearly in the same condition as when stacked, until spring. Then by employing a little fresh litter to render the sides of the bed firmer, moistening the leaves with water, a good bed 5 feet high in April, 4 feet in May, may be formed, and it will be less violent in heating than stable-dung, but more lasting. With a supply of leaves, and the mowings of lawns, the heat may be maintained by

lining the bed as the declining temperature indicates that a renewal is necessary. Oak and Beech leaves are the best for this purpose.

There are, besides, many vegetable substances, such as nettles, thistles, and other refuse growing by hedges, which with the remains of the flower garden, as Hollyhock stalks, Pea haulm, and a host of other things, cut into six-inch lengths, dried in the autumn, and kept over winter in any dry place, form excellent substitutes for stable litter in spring. The above and many other fermenting materials thoroughly moistened by sprinkling either with water or liquid manure, and formed into a bed 4 feet high, will raise a gentle heat, especially if some green vegetable matter, such as nettles, short grass from lawns, and weeds of all kinds, be mixed in to hasten fermentation. With a plentiful supply of such materials, which can be had in any country place for the trouble of collecting, there is no difficulty in growing Melons of good size and flavour. Any deficiency in the heat of the bed afterwards can be rectified by collecting a further supply of materials in a green state; but for maintaining the heat nothing is better than the short grass furnished by the mowing of lawns.

Other substitutes for stable litter are found in cotton waste, the refuse of wool commonly called willy-dust, flax refuse, and spent hops. All these are first-class materials for furnishing bottom heat and maintaining a suitable temperature for the growth of the Melon. A bed 2 feet in thickness of cotton and wool waste or of hops, and 3 feet of flax refuse, is equal in heating properties to a bed of dung 4 feet thick. They require to be moistened with water, but not so much as dung. If made very wet the cotton and wool waste will not heat at all, or, if they do, the heat will be violent and soon over: just moistened is the proper condition. Hops need no watering; flax refuse about the same as stable litter, but if anything rather less. All, after having been employed for growing Melons, are excellent manures.

ECONOMISING HEAT.—If the means at command are limited to the making-up of a bed; or if the Melons are grown in pits without linings, it becomes imperative to collect as much of the sun's heat as possible. This is effected by giving what air is necessary to cause a change of atmosphere early in the day; when the thermometer reaches 80°, which it will do in May and later in the season by 8 or 9 A.M., open the lights by tilting them at the back. Giving air by pushing down the lights only causes a current of cold air to rush in at the bottom of the frame and out at the back, which is injurious. Air being admitted early, it should be shut out early. Presuming that there is no heat in the bed calculated to raise the temperature more than 5° or none at all, the frame or lights may be shut up by 2 P.M. in May, 3 P.M. in June and July, 2 P.M. in August, and 1 P.M. in September. Any watering that may be required should be done before the frame is closed, a gentle bedewing overhead at the time of shutting up being of great benefit to the plants, and a great annoyance to the red spider. Though these hours of shutting up will prove generally applicable, yet, as all days are not equally sunny, a good deal must be left to discretion. If, after closing, the sun's rays do not raise the temperature above 90° or 95°, no harm will ensue; but if the heat rise above 90° it must be reduced by admitting a little air. The frame may at any time be shut up with a temperature of 90° if there is no likelihood of great sun heat afterwards, but always before the temperature of the frame falls below 80°; and if the sun raise the thermometer 10° after shutting up so much the better. The heat shut in or collected afterwards will be better than a high artificial heat.

Melons grown in the above manner will not require so much water as those in frames with a strong bottom heat—in fact, none should be given them beyond enough to keep the soil moist whilst the fruit is swelling, and this may be done by a good watering once a-week, which, in addition to sprinklings overhead at shutting-up time, will be all that is required. Sprinklings will not be required in dull cold days; and when the blossoms are setting no water should be given either overhead or to the soil, nor after the fruit has attained its full size and commenced the ripening process, which is when it becomes fully netted. The fruit after setting is longer in arriving at maturity in this way than when a

higher and more regular temperature is maintained. It usually takes from fifty-five to sixty-five days to bring Melons to maturity in cold frames.

SECOND CROP FROM THE SAME PLANTS.—Plants fruiting in June and July may be made to furnish a second crop; but it is well to prepare them for this as soon as the fruit has attained its full size by encouraging five or six of the strongest vines starting from or near the necks of the plants, stopping at the first leaf those that appear above them, or cutting them clean out if the large leaves are healthy on the vine or shoots producing fruit. Other shoots not producing fruit should be cut out, so that the strength of the plant may be concentrated in the shoots selected for furnishing a second crop. No water need be given, for the young shoots will take that which would be expended in useless growths, and will feed on the matter stored up in the large fleshy roots, and so grow luxuriantly without the aid of water for a period of a fortnight or more. If the plants have not vitality to push strong shoots a foot long between the time of the fruit becoming fully netted and that of its ripening, they are of no value for a second crop, and had better be pulled up, the bed and soil renewed, and young plants put in their place. Young plants will furnish larger crops and finer fruit, but about six weeks later than old plants from which a crop of fruit has been taken.

When the fruit on the old plants is ripe cut away the old shoots, renew the lining of the bed, taking away as much of the old limings as can be conveniently done, and remove the surface soil of the bed with the hand to the depth of 2 or 3 inches, more or less as the situation of the principal roots may determine. A little of the old soil may be removed between the large roots, always bearing in mind that the less the fibres are disturbed and the large roots injured, the more certain are we of active root-action. After removing the old soil water each light with water at a temperature of 90°, and then cover the surface with 3 inches of fresh compost, pressing it firmly around the roots. In doing this care should be taken not to remove any soil within a radius of 1 foot from the neck of the plant. When this operation is completed give a gentle watering with tepid water, and keep close and shaded by covering the plants until they become re-established, after which they require the same treatment as young plants.

SHADING.—Melons do not require shading at any stage of their growth if they are properly inured to light from their first appearance from the seed. It always struck me as strange how any one could imagine a plant so capable of bearing so much heat and dryness as this could require shade from the sun, and that in a climate where the sun's rays are much less powerful than in its native home. I have never found it necessary to shade Melons, except a little after planting-out in bright weather to further their taking hold of the soil; and after a continuance of dull weather, when the plants sometimes flag, a slight shading is necessary. Beyond this I do not consider shade favourable to the production of fine full-flavoured Melons. Though shade may increase the size of the fruit, I am certain that any fruit formed whilst the leaves are not duly exposed to all the light is never so full-flavoured as that formed when they are so exposed.—G. ABBEY.

(To be continued.)

AN AMATEUR'S PENCILLINGS.

THE BROMELIACEÆ.

SURELY the attractions of this tribe of plants are much less known than they deserve to be, or else they would be seen more frequently, and in much greater numbers, in the stoves and conservatories of our plant-growers, ever on the look-out for the novel and the beautiful. I will, *meo more*, tell you the story of one which has just delighted me and my household, and has won golden opinions from wondering and admiring friends. Years ago, in the forests of tropical and sub-tropical America, the strange and often gorgeous parasites of this order forced themselves on my notice and strongly attracted me; and to this day the Wild-pines,* as they are called by the colonists, form one of the most promi-

* Pronounced as one word, with the accent on "Wild."

uent features of the vivid pictures which memory calls up of the forest scenes in lovely Jamaica.

The little negro villages in that island, groups of huts which shrink with an old instinct from the white man's gaze into the secluded glades and unsuspected nooks of the forest, are surrounded by inviolable *chevaux de frise* of *Pinguins* (*Bromelia pinguin*), a large-growing species of the tribe. This prickly bush, at first planted in line as a fence, rapidly spreads, and covers a broad area when neglected and allowed to follow its own will, as it usually is, at least on the exterior; a result perhaps not unwelcome, as it makes approach to the sable homesteads more difficult. The fence is absolutely impenetrable by man or beast; nothing less than an elephant or a rhinoceros would face it. When not in flower or fruit you would scarcely distinguish it from the cultivated Pine Apple, another species of the same genus; but it is more vigorous and formidable, the long channelled leaves which arch out on every side from the centre being beset along their edges with strong recurved spines, exceedingly sharp, and capable of inflicting terrible wounds. In March the *Pinguin* blossoms, and then it is a beautiful object, the central leaves becoming of the most brilliant glossy vermillion, and the thick erect spike of bloom of a delicate pink white. This is replaced by a dense head of hard woody capsules, not united into a succulent fruit as in the Pine Apple, but separate, though closely packed. They contain an intensely acid juice, which is pleasant to moisten the lips or tongue, but is found to be acrid and caustic if used too freely.

On the rocky sides of gloomy gorges cut through the ranges of limestone mountains, where a narrow and precarious footpath often borders a rushing torrent, we see springing out of the clefts tufts of different species of the genus *Pitcairnia*, for the most part resembling tussocks of coarse grass, whose spiny blades arch and droop in elegant curves; while, if the season be spring, the centre of the crown is adorned with spikes of long tubular blossoms, scarlet, or pink, or white, according to the kind.

Much more striking, however, are those genera which are parasitic on trees, and these are eminently characteristic of the scenery in the warmer regions of the western hemisphere. They are found in all situations—on the tops of the mountains, in the low sunburnt plains, by the shore of the glittering sea, in the depths of the gloomy forest, in the open savannah—wherever a tree will grow, there also is a place for its *fidus Achates*, the epiphyte Wild-pine. They affect all sorts of trees, scarcely a tree being without one or more, large ones often carrying hundreds: nor do they seem to attach themselves to dying or diseased trees more than to such as are in perfect health. One species, called Old-man's Beard (*Tillandsia usneoides*), is very abundant. In the great swamps of the southern Confederate States the sombre evergreens, that almost shut out the light of day, have their gaunt limbs densely clothed with ragged pendent festoons of this grey parasite. It is small and slender individually, but forms immense matted bunches, with wiry flexible stems of indefinite length, intertwined and tangled together. These are of a pale yellowish green hue, especially near the tips, where the young leaves appear, most of the plant being covered with a hoary greyish sort of down. The leaves sheath the stem, and each other, at their bases, and project so little as scarcely to affect the general filiform appearance. So readily is it propagated, that a bunch torn off and flung into the fork of a tree will immediately take root and spread rapidly. The fibres, divested of their outside coat, make excellent mattresses, and are a good substitute for horsehair, from which it is scarcely possible to distinguish them by the naked eye. I have found it a capital material to stuff bird skins.

Other kinds, however, are far more attractive than this. There is one, *Tillandsia bulbosa*, which seems to be spread all over tropical America. It has a globose base, much like the bulb of a Lily, and narrow, almost cylindrical, pointed leaves, of which those near the blossom are of a fine crimson hue. A spike of flowers, lengthened in form, and of crimson and purple hues, with singular sheathing bracts, and projecting purple stamens, makes this a beautiful plant in the blooming season. Like the rest of this genus, it is a difficult plant to reconcile to artificial habits. The *Tillandsiae* are the most stubborn of the order. We import them, possibly

flower them one season, and then they die, without propagating their lovely but churlish forms. I have one or two specimens of this kind, which I imported from the mouth of the Amazon two years ago. I have planted them on the top of a brick pier in an Orchid-house, where they continue, looking healthy enough, but making no growth, and sending out no offsets. Fortunately the majority of the tribe are more persuasible than this, or I should not be singing their praise in a horticultural journal.

Different species of *Vriesia* and of *Aechmea* are found abundantly in the mountain woods of Jamaica; the former throwing out long simple, or branching spikes of crimson and yellow flowers, imbricated or sheathed in a singularly compact manner; the latter gorgeous in scarlet and purple. But the most imposing of all that I have seen there is the noble *Billbergia lingulata*; the leaves are long and shaped like those of the Pine Apple, but widened, and, as usual in the order, sheathing each other at their bases; and in July they protrude a spike of large flowers of the richest crimson hue and of a polished surface. The sheathing bases of the coriaceous leaves of most of the epiphyte species form natural reservoirs for water: the rains and dews accumulate here in considerable quantity, and form a resource for thousands of birds, and even for man himself, in the season of drought; while the spacious reservoirs afford retreats, always cool and moist, for such reptiles as respire through their skin. The various species of tree-toads, often of large size and fantastically brilliant colours, habitually dwell in them, and sitting in their comfortable baths give utterance to such deep snores, such gurgling throttling groans, and such shrill piercing shrieks, as startle the benighted traveller in the solemn forest with sudden thoughts of murder and mortal agony.

Such were my associations with the Bromeliaceæ when in the spring of 1862 I began to grow them. I had just erected a small house for the cultivation of a group in some respects, as to habitat, habit, and singular gorgeousness of beauty, kindred in character—viz., the Orchideæ; and I felt a strong desire to renew acquaintance with my old friends the Wild-pines.

In Carter's catalogue of seeds for the season, I had noticed *Billbergia zebra*, which I knew to be a fine Brazilian species; and, though I was not very sanguine of success in raising Bromeliaceæ from seed, I sent for a packet, and sowed it at once. This was the 8th of March, and on the 25th the tiny plants, like little points of grass, were peeping. They grew on, the sheathing character of the leaves manifest from the first, and soon they required to be pricked-out. As we commonly find with seedlings that some much exceed their fellows of the same batch in size and vigour, so here one *Billbergia* soon outstripped all its compeers, and grew apace. I shifted it as it needed, draining the pots well, and giving a greater proportion of loam as it increased in size. From November to March it was allowed to rest, and scarcely received any water. By the time it was two years old, that is to say, in the present spring, it had attained noble proportions. It was now in an eight-inch pot, the main crown about 2 feet high, but the longest leaves were full 3 feet measured along the curve, and 3 inches in diameter. For more than half their length they take a semi-cylindrical form, sheathing each other below, and thus giving to the body of the plant the appearance of a deep but narrow vase. Water always stands in this cup, and in the hollow bases of the individual leaves. These organs are spinous at the edge, but not strongly so; their colour is a glaucous or greyish green, as if slightly mealy, and on their exterior they are marked at irregular intervals with undefined transverse bands of white, whence the name of *zebra*. Three vigorous offsets sprang out from the base, augmenting the stateliness of the plant, like three princely daughters supporting their queenly mother.

We had been looking for the flower-spike to appear, and had from time to time peered curiously into the dark depths of the vase-like hollow, but without success, till suddenly on the 10th of June, a thick cone came up from the interior, and showed its apex above the united leaves. It now lengthened with wonderful rapidity, pushing up in the form of a great pointed oval of 7 or 8 inches in length, and all over of the richest and purest rose colour. When this was pretty well visible above the tube, standing erect, it suddenly began to lean from the perpendicular and on being

touched was so unstable that I feared it had been broken at the base by some accident. However, it continued to lengthen with increasing rapidity, and also to fall over, until it hung down with a sharp curve. At the same time the tips of the green flowers began to protrude from the summit of the great rosy egg, and soon the ample convex bracts, of elegant shape, and spotless purity of colour, opened, and the massive thyrsus of many blossoms was revealed. These I can compare to nothing so well as a cluster of short reeds, each about 3 inches long, pointed, polished, green, with its base enlarged, in form of a sculptured knob, which was encased in an envelope of pure opaque white.

As the thyrsus continued to grow, the lengthening axis became distinct, stout, cylindrical, and of the same snow-white hue. The lower flowers now began to open, each in its turn; and a new peculiarity entertained us, for what had hitherto seemed the undivided green skin of the short "reed," split into three strap-shaped divisions, which then quickly rolled themselves up scroll-fashion, as you might roll up a narrow strip of paper, and finally projected in three bundles just above the white envelope of the basal knob. Thus it was manifest that these three light green straps, which as they rolled up reflected a satiny lustre, were the petals of the corolla, and the white envelope, which terminated in three points, was the calyx surrounding the knob-like germs. The rolling back of the petals exposed the stamens, which clung together as a long straight fascis, of a greyish green hue, each terminated by its anther in the same line, and the pistil projecting from the midst. It was interesting to note how the anthers instantly began to open as soon as they were exposed, and to display the black pollen of their interior.

Observations of these phenomena beguiled my wife and myself of an hour's sleep. I had removed the plant, on the protrusion of the thyrsus, from the hothouse into the drawing-room, where it attracted no small attention. When night came, and we were about to turn down the lamp, we noticed that the petals of one flower were just separating at their tips, and saw one start up, and roll itself over in the first coil of its curious scroll. This one, then, we sat down to watch, and for a full hour our eyes were steadily fixed on the flowers, as one petal after another rolled back. Our impatience induced us to assist nature, by just lifting with a pin's point now and then, when the adhesion of the petals' suture was more than usually strong, or the coiling more than ordinarily tedious. The process occupied about an hour to complete it, and was visible only by our setting the position of the coil against some immovable part, and looking at it again in a few minutes; it was rather less than that of the minute-hand of a watch. About three complete turns perfected the scroll.—P. H. GOSSE, *Torquay*.

THE ROYAL HORTICULTURAL SOCIETY.

ON Tuesday last a lecture on the Rose was delivered at the Garden of the Royal Horticultural Society, at South Kensington, by the Rev. W. F. Radclyffe, of Rushton, Dorsetshire. One would have expected, from the popularity of the lecturer, and the universal interest with which his subject is regarded, that there would have been a large attendance on the occasion. We regret, however, to state that, with the exception of a few familiar faces, the audience was one which would have discouraged even the most indifferent; and we are much mistaken if the Rector of Rushton puts himself to the trouble and expense again of travelling nearly a hundred miles to oblige the Royal Horticultural Society, after such treatment as he received on this occasion.

As is usual in all cases where the legitimate objects of the Society are concerned, there was no trouble taken to give publicity to this meeting. Had it been an entertainment of the Mumbo Jumbo class, or an evening meeting to burn gas and blue lights, the announcements would have met you at every corner; but as it was only a gathering of horticulturists, they could tell each other, and that would suffice.

But what if the lecturer himself was not told? We have the best authority for stating that, from the time Mr. Radclyffe consented to deliver this lecture, he was not officially, by the Secretary, nor by any other person, informed of the

time when it was to take place; and it was not till the evening before the lecture was to be delivered that he was informed, by electric telegraph, that his presence was required. Can it be wondered at that the affairs of the Society should be so muddled when they are entrusted to the management of people so utterly incompetent to fill the offices they so doggedly, yet so inefficiently, hold? When the Assistant Secretary goes wool-gathering he should leave the message-boy or some other competent person in charge.

Notwithstanding the small attendance, the audience consisted of those fully able to appreciate the subject. Sir Daniel Cooper, Bart., occupied the chair; and the only other member of Council present was the Rev. Joshua Dix. Among the audience we observed Drs. Lindley and Hogg, Messrs. Thomas Moore, R. Fortune, William Paul, George F. Wilson, W. Beattie Booth, Charles Turner, &c., &c. After some preliminary business, Mr. Radclyffe proceeded:—

"I thank the Council of the Royal Horticultural Society for the high compliment which they paid to me in asking me to give a short, popular, and useful lecture on matters connected with the Rose. As the time is limited, and as 'a great book is a great evil,' I can only select. I will endeavour to avoid prolixity, laxity, and obscurity. Nothing new can I say—nothing that has not been said before, and said much better. The best lectures on the Rose are the noble works of Rivers, W. Paul, and Cranston—works that should be in the library of every rosarian. Good, however, and truthful as these works are, I am persuaded that nothing but experience can make a man a first-rate rosarian. I will endeavour to speak from experience, making this observation, that all, or almost all, I shall say, has been given already to the public in my published articles from time to time.

"1. *Soil.*—The best soil for Roses, and for such stocks as I possess, is friable loam. Where this soil exists not naturally, it may be approached by an admixture of stiff soil, sand or ashes, and black manure, in equal parts. Oak trees, Roses, and Strawberries have all an affinity for clay. I had nearly said they are convertible terms. Still, even where there is not a particle of clay, which is the case where I live, certain Roses, on suitable stocks, with good high cultivation and attention, may be grown, and very fine Roses too. There are also Roses that cannot be grown without an admixture of clay. I need hardly say these are Roses which, though good in themselves, are not fit for the public generally.

"2. *Planting.*—Much depends upon how this is done. Briar Roses should not be planted deeper than 4 inches; indeed, if people would mulch the plants in a radius of 18 inches, they may be planted nearer the surface. Manetti Roses should be planted over the collar of the bud: and hence they should be propagated sufficiently low that the sources of the roots are not deeper than 6 inches.

"3. *Staking and Tying.*—All freshly-planted Roses, especially if exposed to wind, require to be staked and tied. Iron stakes are the best; but I use, for small plants, thatchers' spars 6s. 6d. per 1000; and, for strong plants, I use hurdle shores, at 7s. per 100. For tying I use matting. Where winds do not prevail, after the first year ground plants and two-feet standards (the most convenient height where numbers are to be packed in) will not require staking and tying. If ground plants are grafted they must always be staked and tied, or the weight of flowers will break them off at the point of union.

"4. *Rose Stocks.*—The Dog Briar, the Manetti stock, and the Celine stock, are all good stocks for certain Roses under certain circumstances. Roses are volatile things, and all rules admit of exceptions: in the rosery there is not, as in our courts of law, 'rule absolute.' As regards the Celine stock, I know but little of it. Mr. Wood, of Maresfield, kindly gave me four specimens of the Duchess of Norfolk on this stock, ranging, with shoots of one year's growth, from 12 feet to 12 feet 9 inches high. They bloomed admirably last year at their full height. This year I shortened to 9 feet, and they have again bloomed well. I budded last year the Due de Rohan, a splendid vermillion Rose, on the Boursault Amadis, and it has thrown up a fine truss and bloomed well. As regards the Briar stock, it is an admirable stock for strong lands, and better than the Manetti stock for dwarf and moderate growers; but, if land is light or shallow, unless you can afford to replenish constantly, and

also to mulch, you had better have Roses on the Manetti stock. This stock is suited to strong growers, and to all lands. Though an Italian stock, it is, on well-drained grounds, the hardest of all. In such inferior lands as mine, Roses budded *in loco* on the Briar, and manured very highly, bear no comparison with purchased Manetti Roses for earliness, abundance, and largeness of flowers, and for lateness and continuity of flowers: still, put Briar Roses in suitable land and it will do splendidly for you. For pole purposes the Manetti stock is, I think, the best.

"5. Pruning.—Some people prune on a particular day, and prune all Roses alike. Excellent rules are given for the pruning of all families in the three noble works before referred to. It must not, however, be forgotten that Roses in the same family require very different pruning. Among the Bourbons there is a world-wide difference between Acdalie and La Quintinie. As regards a Briar Rose, in the spring of its first planting, or whenever it is moved, it is a rule that it must be cut hard, whether it be for a pole, wall, or standard. For lack of this Briar Roses frequently fail. Till, however, the sap rises, and the eyes swell, you must never prune. As regards Manetti Roses, they often fail from being cut hard. From first to last prune them as Hybrid Chinas, whether pot plants or monstrous plants. If their wood and skin are injured, then you must cut them down to sound wood and sound skin.

"6. Growth and Hardihood.—These do not always go together, but both are requisite for England. Some that have China blood in them grow well, but yet they are not hardy. As a rule the thorned Roses are hardier than the smooth-skinned Roses. Of course there are exceptions in both cases. When, therefore, you see a novelty described as thornless, remember it may be no recommendation. I ventured, some years ago, to say, in an article, that none but vigorous growers would suit the English; and the consequence has been, that raisers of seedlings have erased the words 'dwarf' and 'moderate,' and now almost every new Rose is described as 'vig.' I am told that some of the new Roses of 1864 described as 'vig.' are very dwarf and bad growers. 'Moderate,' in the fine lands of nurserymen, will be 'dwarf' in ninety-five lands out of a hundred, and 'dwarf' means death. The two best moderate growers, and both hardy and excellent, are the well known Giant of Battles and Pauline Lanzezeur.

"7. Watering.—Roses suffer much in torrid weather from lack of water. Before watering the ground should be surface-stirred, and sufficient water poured over the roots to touch all the points of the roots. If the surface is kept superficially stirred, it will be moister than when kept corked down tight, because a lesser quantity of rain, and the night dews, which are in the ratio of the sun's heat, will be able more easily to penetrate the soil.

"8. Syringing.—A great many of the miseries of Roses would be got rid of if the trees were regularly syringed from the earliest appearance of the leaves. By keeping the lungs clean you preserve the health of the plants. The leaves of plants are externally and internally conducive to health. Syringing is the best thing to keep down fungi and aphides, and also to prevent the mischief of honeydew, which, if not washed off as soon as perceived, will, by the sun's extraction of the fluid parts, leave a viscous concrete, that will destroy the functions of the leaves.

"9. Fungi.—These are a numerous family. The two most destructive are orange fungus and white fungus. Orange fungus must be picked off by hand before the nucleus bursts and spreads its spores over the leaves; and white fungus must be destroyed by sulphur (the black sulphur is best), or by 2 ozs. of blue vitriol, dissolved in a little hot water, and then mixed with a stable-bucket of cold water, and poured from a watering-pot, with the top on, over the leaves. This is the most effectual remedy. There is another misery, 'black blight.' This is also called by some a fungus. It may be so; but I could never perceive the spores of fungus. It proceeds, I believe, from a low state of temperature, also from checks of weather. I am inclined to think this, because I never remember seeing it under glass, which is no preventive of white fungus. It is less mischievous than either of the other two miseries. When it occurs early in the year, if the leaves are universally affected, stirring the ground deeply, or removing the plant,

to stop the sap, are probably the best preventives of mischief.

"10. Wind.—Roses cannot have too much air, and too little wind, in the growing season. At other times it is beneficial. Great havoc every year has been committed on my rosery by the destruction of the leaves by wind. This season the wind has been quiet; but in ten of the months last year there were from one to five gales monthly.

"11. Novelties.—Do not give up such good and hardy Roses as the Giant of Battles and Baronne Prevost. They have outlived hundreds at my residence, and are as healthy as they were twelve years ago.

"Tis good to be on with the new love
Before you are off with the old."

No question, good Roses come out yearly; but we want not only good Roses, but better than we have got: we want more distinct Roses. As regards form, we need more cups and globes; as regards colours, we want true purples (now supplied by Alfred de Rougemont), full-sized autumnal pure whites and creamy whites, yellow Hybrid Perpetuals, variegated Peppertials, high-coloured Teas, and more full-sized, full, very dark Roses. In the dark line we have Empereur de Maroc, small, but beautiful and full; Princesse Mathilde, dark, shelly, beautiful, but not full; François Arago, full and good; Due de Cazes, dark, full, and fine; and Alfred de Rougemont and Prince Camille de Rohan, both very dark, full, and fine. There is one new Rose very interesting, tolerably dark, and also good—a Rose of royal and national interest—Deuil de Prince Albert, or the Mourning of Prince Albert. Mr. Rivers has well said, in a letter to me, that it is, from its darkness and mournfully-pendulous habit, well adapted to represent the royal and national, and, I may almost say, world-wide sorrow at so sad an event. I caused it to be mentioned to Her Majesty by my friend Lord Rivers; and I cannot but think that this Rose, and such-like as I have named, would be very appropriate to adorn the mausoleum, and also suitable to this Royal Garden, so indebted to Her Majesty and the late Prince Consort.

"Lastly: The Selection of Roses.—I think you cannot do better, if you do not know the Roses, than state to the nurserymen what are your circumstances and wants, and, though they cannot for several years be quite sure about novelties, I am sure they will not wilfully deceive you. The old 'stuff' they well know; but they cannot, in the case of novelties be sure of them till they have passed through severe winters and unpropitious summers, or tell their true value or worthlessness. I think the nurserymen should take some security from the raisers of seedlings that the Roses are according to description; and I also think that they should make inquiry as to the 'suppressio veri,' as well as take security against the 'expressio falsi.'

"It now only remains to thank you for your kindness, and to hope that what I have said may create true rosarians. Your well-known love of the Rose must be my apology for this prolonged address. I hope that I shall not commit a breach of good taste if I express my thanks to Her Majesty for originating this great Society; if I thank the Society, on behalf of all rosarians, for their splendid patronage of the Rose cause; if I express my far greater gratitude to Him from whom, and through whom, all blessings flow, who is the 'Rose of Sharon and the Lily of the Valley.'

FLORAL COMMITTEE.—A meeting of the Committee was held on the 19th inst., but no plant or flower of any particular interest was exhibited, the subjects for examination being unusually few for the time of year.

Mr. William Paul sent two seedling Hybrid Perpetual Roses—namely, Dr. Lindley, dark rosy crimson, fine full flower, of promising qualities, but not in condition; and Rosea elegans, a bright light rose, but deficient in substance and quantity of petals. A second-class certificate was awarded to the first named. From Messrs. Carter and Co. came a hybrid tree Carnation, called Goliath, indistinct in colour, highly scented, but by no means an ornamental flower. Mr. Bull, Chelsea, sent Cypripedium superbiens, not sufficiently distinct from other well-known varieties; Achimenes Leonie; Tropaeolum Gold Belt, yellow flower with deep orange spots on each petal; and Weigela alba lutescens grandiflora. From Mr. Perry, Castle Bromwich, came cut flowers of six seedling Verbenas, of which Snowball had an

average truss, and most beautifully-formed flowers, nearly circular and flat, the eye rather too green, and the white ground slightly tinged with pink, decidedly the best formed white we have. This received a second-class certificate. Glowworm, dark red, with a large conspicuous eye, if of good habit, will make a very effective bedding plant. The others were Delicata, bright rose; King of Lilacs; George Tye, pale violet, with large white eye; Queen of Pinks, a rosy carmine—all of them very nice flowers, but not distinct in colour from others. Mr. Perry also sent a stand of twenty-four Verbenas in first-rate condition. Among the sorts especially good were Black Prince, Firefly, Foxhunter, L'Avenir de Ballent, Cato, and some good unnamed seedlings. A special certificate was awarded for this beautiful collection.

Mr. Holland, Isleworth, sent *Asplenium trichomanes subæquale*, a plant of peculiar flat growth, the fronds lying on the surface of the pot, a distinct variety, for which a second-class certificate was awarded; also, *Cyclamen Peacockianum*, which had been exhibited before. Its propensity to continue flowering seems to be its great recommendation. In colour and form it is not equal to others. Mr. Holland had a first-class certificate for *Petunia Striata perfecta*, circular form, pale rose, striped with white bars, very constant in its colour and markings, a very free bloomer, and of good habit, likely to be very useful. Messrs. Downie, Laird, and Laing contributed *Pelargonium Golden Sceptre*, of the Mrs. Milford character. Such seedlings are innumerable, and not easily to be distinguished. Messrs. Paul & Son, Cheshunt, exhibited English seedling Hybrid Perpetual Roses, Lord Canning and Lord Clyde, the former a bright globular rosy carmine flower, but wanting in substance of petal, and too thin. It was requested that this might be seen again. The specimens of Lord Clyde were beautiful; it is the most brilliant in colour of its class; their seedling Rose, Hamlet, was also shown by Messrs. Paul. Mr. Windsor, gardener to Lord Dufferin, Highgate, sent four seedling Scarlet Pelargoniums, Blair Athol, Gem, Grandis, and Highgate Rival. The last, which received a second-class certificate, was a very good flower, a bright shaded orange salmon, with broad flat petals, very free flowering, and forming a fine truss. Mr. Young, gardener to R. Barclay, Esq., sent four seedling Gloxinias.

It would materially assist the Committee in deciding on the merits of seedling Verbenas, if the exhibitors would state whether the flowers sent for examination were grown under glass or in the open air. It must be evident to every cultivator of this beautiful flower, that the value of a Verbena, both as respects colour and habit, depends much on its being able to resist the influence of the sun's rays, and the effects of rain.

FRUIT COMMITTEE.—A meeting of the Fruit Committee was held at Chiswick on Thursday last; Mr. Edmonds in the chair.

A requisition was some time ago presented to the Council by the Committee, requesting that the meetings, which have been discontinued since January last, should be resumed, and that Dr. Hogg should be asked to accept the office of Honorary Secretary to the Committee; in accordance with the arrangement made between the Council and Dr. Hogg this was the first occasion on which a meeting had been held this season.

The Committee first proceeded to the examination of a collection of twenty-four varieties of Red Currants, many of which were found to be synonymous with others, and many to possess no particular merit. Red Cherry and Fertile were synonymous; Pitmaston Sweet Red, Late Red, and New Sweet Red were the same as Victoria; New Red Dutch the same as Red Grape. In the opinion of the Committee the best variety for flavour was Red Cherry, and the second best for flavour and cropping the Red Grape. The Red Grape is by many considered the same as Red Dutch; but, while it is as great a bearer, and produces as large bunches and berries, it is distinguished from it by the long, slender, yellow footstalk of the bunch, and the pale red colour of the berries; the colour of the Red Dutch being a dark ruby.

The Committee then examined the collection of prize Gooseberries, or, as they are improperly called, Lancashire Gooseberries, of which there are 176 varieties in the garden. A large proportion of these are perfectly worthless as regards

flavour, and have only their size to recommend them; but there are also some that even as dessert fruit possess high qualifications: we shall, therefore, give a selection of those in each class that deserve to be cultivated for their flavour.

REDS.—*Companion*, a bright rough red, with rich flavour; very excellent. *Speedwell*, rough light red, thin-skinned, with a fine grape flavour. *Ricardo*, bright rough red, coarse flesh, but good flavour.

YELLOWS.—*Broom Girl*, rough, and thin-skinned, tender flesh; very fine flavour. *Fanny*, rough thin skin; very rich and excellent. *Perfection*, thin-skinned, tender flesh, and with a fine melon flavour. *Two-to-One*, thin-skinned, tender flesh; good. *Goldfinder*, a large, long, rough yellow; very richly flavoured. *Leader*, a smooth dark yellow, large, thin-skinned, tender-fleshed, and with a very rich flavour. *Moreton Hero*, smooth light yellow, thin-skinned, and very richly flavoured. *Legerdemain*, very large and long, smooth and thin-skinned, tender flesh; good flavour. *Candidate*, long, smooth, thin-skinned; very tender and rich. *Tiger*, long, smooth, thick-skinned, coarse flesh, but good flavour. *Gipsy Queen*, thin skin, delicate flesh, and richly flavoured.

GREENS.—*Model*, rough thin skin; richly flavoured. *Green Prince*, thick skin, coarse flesh, but good flavour. *Gretna Green*, rough thin skin; good brisk flavour. *Tantivy*, smooth thick skin, coarse flesh, and good flavour. *Slave*, smooth thin skin, very tender flesh; good flavour. *Beeston Castle*, smooth thin skin, tender flesh, very fine and rich. *Lord Eldon*, smooth thin skin, tender flesh, sweet, and very rich. *Sir Charles Napier*, smooth thin skin, tender flesh; good flavour. *Telegraph*, immense bearer; smooth thick skin, coarse flesh, but good flavour. *Arthur*, smooth thin skin, tender flesh, good flavour. *General Markham*, skin smooth, thin; flesh tender and nicely flavoured. *Safety*, long and smooth; skin thin, flesh tender and of good flavour. *Random Green*, immense bearer; very large long fruit, thin skin, tender flesh; excellent flavour. *Green Overall*, smooth downy thin skin, tender and melting flesh, and delicious flavour. *Lofty*, very thin hairy skin, tender flesh; very rich and delicious. *Keepsake*, fine large hairy fruit, thin skin, and deliciously flavoured. *Green River*, smooth, thin skin, tender flesh, and good flavour.

WHITES.—*Lady Leicester*, oval, rough, thin skin, tender flesh; sweet and good. *Snowdrift*, round, hairy, hard flesh, but good flavour. *King of Trumps*, oval, smooth, rather firm flesh; excellent flavour. *Moreton Lass*, round, slightly downy, thin skin, tender flesh; good flavour. *Snowball*, roundish, downy; fine flavour. *Tally-ho*, large and long, hairy, thin skin; very fine flavour. *Jenny Jones*, smooth thin skin, tender flesh; melting and richly-flavoured. *Flora*, smooth thick skin; good flavoured. *Eagle*, smooth thick skin; fine flavour. *Mayor of Oldham*, smooth, very thin skin and tender flesh; exquisite flavour. *Patience*, smooth, tender skin and flesh; very fine flavour.

CHANGING OCCUPATIONS.

You have given at page 49 good practical advice in reply to a Yorkshire village tailor, and it has struck me that "a fellow feeling should make us wondrous kind," and induce us to point out a few footprints on the rough sands of time, by way of encouraging the heart of a forlorn brother.

To the Yorkshire village tailor, then, I say, Make up your mind to be a gardener—first, because you seem to have a natural love for the occupation; and, second, because you wish to regain health and strength. If you have the means of starting a little business in seeds and plants, or a little market gardening business, the road to success is sure enough, since you have the will. If you cannot hoist your standard quite so high, get a few rods of land in the parish allotments, and devote a few hours a-day to its cultivation. This, with the aid of THE JOURNAL OF HORTICULTURE, will soon enable you to know more about gardens and gardening; and, should your health get established, perseverance will soon work out a wished-for success.

One of the most successful florists of the day was a journeyman shoemaker when I was a boy. He began by growing a few plants, and sending them for sale on a pair of trucks to a neighbouring town once or twice a-week.

The writer of this in the year 1840 was a very small boy in a country printing office nearly 100 miles from London. In

1851 he was a clerk in a large print warehouse in London. In 1855 he was a bookbinder in Paternoster Row. In 1864 he is florist, seedsman, &c., with a business supporting from twenty to thirty individuals. His career as a lover of flowers from the year 1840 to 1864 would fill many a long page. For the Yorkshire tailor's encouragement suffice it to say, he is one of three orphans inheriting weak constitutions. One was apprenticed to a tailor, and died a victim to overmuch confinement in-doors. The other was a clerk in a solicitor's office, and died from similar causes. The writer of this may long since have shared the same fate but for the love of flowers, and his determination to become—**A FLORIST.**

THE BLOOMSBURY FLOWER SHOW.

THIS most beneficial and successful Exhibition was held on the 13th instant, in the garden of Russell Square. There were 795 plants exhibited in the five classes, all of which were fuller than last year, particularly the children's class, which was then very empty. This year every prize was given away, whereas last year several were withheld.

Class 5, which was for plants not entered, was, as might be expected, a very large and showy class. Some people have condemned the introduction of such a class, saying that it was only offering prizes to plants many of which might be purchased on the day of the Show; but the great object of the Exhibition is to induce the poor to decorate their rooms with plants, and by exciting their interest in them to induce them to keep their rooms clean, and to bestow that attention on their plants which is necessary to keep them healthy. Many people purchased plants to exhibit in Class 5 who would not otherwise have had them, and having once become possessed of them, they will in nine cases out of ten take good care of them. Fifty-six prizes were given in sums varying from 10s. to 1s., amounting in all to £14 3s., and to each prizetaker a card was presented with a small picture on it, and a *fac-simile* of Lord Shaftesbury's autograph.

There were, we should think, between three and four thousand people present, and the Police Band and the Band of the 37th Middlesex Rifles attended gratuitously. The tent was supplied by Messrs. F. Edgington & Co., and was nearly 90 feet long and between 40 and 50 feet broad. The plants were arranged on tables down each side, and in a double line down the middle, and looked very well. Some of the best plants exhibited had been in the parish for three or four years. One gentleman gave to the Hon. Secretary, W. H. Bosanquet, Esq., £1 to be offered for the best tree Carnation next year. We fear that there will not be even a small class of that plant. A class for Auriculas or Polyanthus would be more likely to fill. It is of no benefit to offer prizes for plants which the poor are not in the habit of growing. W. Sowerby, Esq., of the Royal Botanic Society, was Judge. The tent was very prettily decorated with mottoes and banners lent by a lady in the parish. One man exhibited some Dahlias in good bloom, and had an extra prize for them. Another sent a small tub with some Potatoes and Radishes growing in it.

The exhibitors were divided into the following five classes:

Class 1.—Persons living in the Little Coram Street district.

Class 2.—Persons living in other parts of the parish.

Class 3.—Domestic servants.

Class 4.—Children in National, Infant, Sunday, and Ragged Schools.

Class 5.—Any plants not entered.

The first prize in Class 1 was taken by W. Thompson, 27, Little Coram Street, for a very fine Geranium. For Annuals, the first prize in this class was awarded to G. Bearden; and an extra prize to J. Verity, 29, Coram Street, for a group of Calceolarias, Stocks, &c. In Class 2, the first was taken by Henry Roberts, 24, Southampton Mews, for a fine Geranium. An extra and well-deserved prize was given in this class to Annie Roberts, of the same residence, for the model of a garden, fronting a toy villa, denominated "Bloom Grove." A brick wall with a neatly constructed gate enclosed the front of the garden, and a gravelled path leading to the mansion was bordered with flowers of every description, including Verbenas, Stocks,

and Fuchsias, mostly in bloom. The whole exhibited great taste. In Class 3 there were some really splendid flowers, which at once showed the more favourable conditions under which they had been reared. In this class the name of Susan Hyde figured conspicuously, and she certainly exhibited some very fine plants, among which may be specially mentioned a beautiful Fuchsia. Elizabeth Griffin showed also a very fine Fuchsia, the best, perhaps, in the Exhibition, and worthy to take a place in a first-rate flower show. In Class 4, the first prize was taken by Julia Turner, also for a Fuchsia. The plants in this class were reared by children, and the care bestowed upon their growth was evident from their fresh appearance. Class 5 consisted of any plants not entered, and contained some very fine specimens of flowers; a magnificent flowering Geranium, exhibited by a person named Wheeler, taking the first prize. Susan Hyde's name (a cook, we were told, to a gentleman's family in Woburn Square), figured here again very conspicuously, and, among other things, was fine fresh Creeping Jenny, reared by a nurse in St. Giles's Workhouse.

At about six o'clock the Rev. E. BAYLEY addressed those assembled. He said he was speaking on behalf of himself and of the parishioners when he tendered thanks on their behalf to the owners and inhabitants of the houses of Russell Square for granting them permission to hold their Exhibition there that day. With reference to the Flower Show, it might speak for itself. At the first Show held in Little Coram Street, they had only eighty-four plants exhibited; at the third, which was held in Russell Square, they had between five and six hundred; and this year they had nearly eight hundred. With reference to the important subject of clean and tidy rooms, eighty-four persons last year sent in their names as competitors for prizes; but this year, having extended their invitation over the whole of the parish, upwards of three hundred had sent in their names as competitors. It had, indeed, been a very laborious task for them to visit the rooms, as they could imagine when he told them that in six weeks Mr. Hill and himself had paid six hundred visits each to the rooms whose owners had entered into competition. He was happy to say, that in this and for plants, in consequence of donations, they were enabled to give extra prizes, so that sixty-six people would receive rewards for clean and tidy rooms. With regard to awarding the prizes, there had been so great an improvement in that part of the parish where they first started the movement, that they had considerable difficulty to determine which rooms were the most worthy of receiving rewards. The only objection he had heard with regard to the movement was, that they intruded upon the privacy of these poor people, but he could assure his auditory that instead of that being the fact, the general complaint was, that they did not visit them often enough.

The prizes were distributed by the EARL of SHAFESBURY. For plants exhibited by adults they consisted of sums varying from 10s. 6d. to 2s. 6d.; and for those exhibited by the children, of sums of 7s. 6d., 5s. 6d., 2s. 6d., and 1s. The prizes for clean and tidy rooms consisted of sums of £2, £1 10s., £1, and 10s., and we may mention that to Mrs. O'Brien, a poor lame woman, was awarded the first prize for clean and tidy rooms.

After the prizes had been distributed,

The EARL of SHAFESBURY expressed the gratification which the business and the display of the day had afforded him. It was a most important movement, and it would effect great objects. It would be the means of teaching the working people how to look after their own affairs, how to improve their tastes and their condition, and raise themselves in the moral and social scale. It was, too, most gratifying to see little children who did not reach to his knee, coming up and receiving their prizes of 7s. 6d. and 5s., instead of seeing them running about the streets and acquiring evil habits and principles. He was particularly pleased with that portion of the movement which related to clean and tidy dwellings. He knew nothing that would more improve the condition of the working classes, and he wished them all success in the good work they had so well begun.

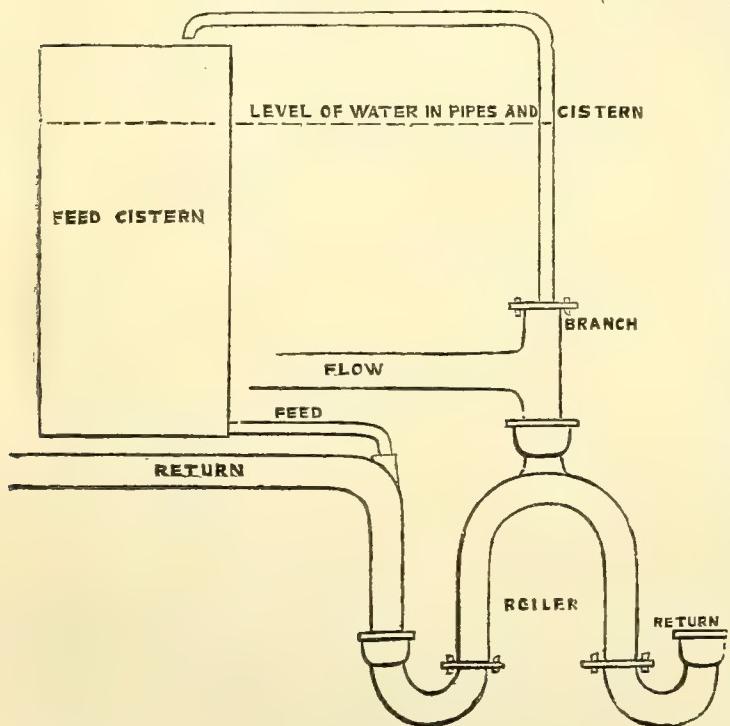

The Rev. E. BAYLEY moved a vote of thanks to the noble Earl for his kindness in coming there that afternoon to distribute the prizes, coupling with the same the name of Mr.

W. H. Bosanquet, the Secretary, who (said the rev. gentleman), deserved their heartiest applause for the interest and trouble he had taken in the whole affair.

The EARL of SHAFESBURY in reply said he hoped next year to come and see the clean and tidy rooms himself.

Number of people who entered their names as exhibitors.....	409
Number of plants exhibited	795

PREVENTING WATER BOILING OVER IN HEATING APPARATUS.

HAVING just seen the questions asked by "ORCHIDOPHILUS," and your admirable remarks on them, I beg to suggest another mode of dealing with the difficulty of water boiling over in heating apparatus, and that a very simple one, as you will see by the enclosed sketch.

It is accomplished by having a branch cast on the top of the flow-pipe, which serves to collect the steam made in the boiler, being higher than the piping immediately in connection with it, and then taking a small pipe, say one-inch bore, from the branch, and letting it terminate with a bend over the feed-cistern. Thus, any water which is sent over before the steam is returned to the feed-cistern, and thence to the boiler.

Before I adopted the above plan I was always annoyed in the same way as your correspondent complains of. Since then I have never heard any complaint. The boiler is one of Messrs. Wood & Tomlinson's, a cast-iron tubular one, the tubes being fixed longitudinally into the horseshoe ends, one of which is shown in the sketch.—P. O. WHITEHEAD.

[We are much obliged, for you certainly have improved on our open pipe by bringing it into the supply-cistern; but if that supply-cistern is large enough you will be troubled with little water or steam from the air-pipe.]

CHANGING THE SITE OF A KITCHEN GARDEN.

I AM thinking of changing the position of my kitchen garden, the present one being on the north side of the house, and so surrounded by high hedges and trees that the birds (jays and magpies in abundance), get at my Cherries and other fruit, and also the Peas. Having been a garden for the last twenty years, I think the ground must be exhausted, for the crops are very poor in spite of being well manured and the ground trenched in the winter. I propose making the new garden in a grass field in front of the house with south aspect, but am deterred rather by the west winds, which blow very strong, and also by the want of water. A hedge will remedy the first, but I do not know how the other will be supplied. The question I wish to ask is, Whether, after the garden is laid out, the grass should be dug in two spits deep and laid at the bottom so as to rot, or should be pared off and burnt, and then scattered over the plots of ground previously dug up. What would be best for a hedge, Privet or Laurel? I wish it to grow up quick. I shall leave the grass for paths, as I can keep them in order by the mowing machine. The intended ground slopes to the south, so that it will have a warm aspect. I am afraid I shall miss the pond which is in the old garden, but must manage as well as I can.

When I was first appointed to the living the old garden was full of large Apple trees with trunks as thick as my body. These I cut down, as they overshadowed the ground, but still it is very unproductive, and that is my reason for wishing to alter the situation. The Asparagus-bed is very old. Could I move any of the young shoots, or had I better buy fresh plants for a new bed? Should I begin to dig the new garden now, or wait till the autumn? —RECTOE, Kent.

[We thoroughly sympathise with you in your troubles. In addition to plenty of other birds, we had the other day for the first time a flight of jays, and hunger and a want of moisture made them very impudent; but they got scared away by the report of the gun. We do not think that the changing of the garden from the north to the south side of the house will save you from the attentions of the birds. We have from curiosity watched blackbirds come and go regularly for a distance of half a mile; and therefore, though the new garden should not have the tree and other surroundings as an inviting harbour and shelter for them, we have no doubt that the birds will soon look after your fruit. There will be no security in the new garden more than in the old except thorough netting, and we have never been able to make netting secure enough to prevent the birds getting a fair allowance. That we would not grudge, but they invariably select the very best.

We are rather surprised with your account of the want of productiveness of the old garden. After removing the old large fruit trees, trenching, and manuring, it ought to have been very productive. The age of twenty years is nothing for a garden. We know some gardens that have been cropped for a period of three or four times twenty years, and now show anything but signs of wearing out. With proper rotations, and even heavy and close cropping, we see no reason why a garden should wear out, if treated as you say yours has been. Trenching, however, may of itself help to promote present barrenness if too much of the subsoil is raised at a time. We have seen ground so trenched that nothing would restore to productiveness but trenching it back again. If the soil is overdone with manure of an organic nature, a little lime would do much to bring its latent powers into operation.

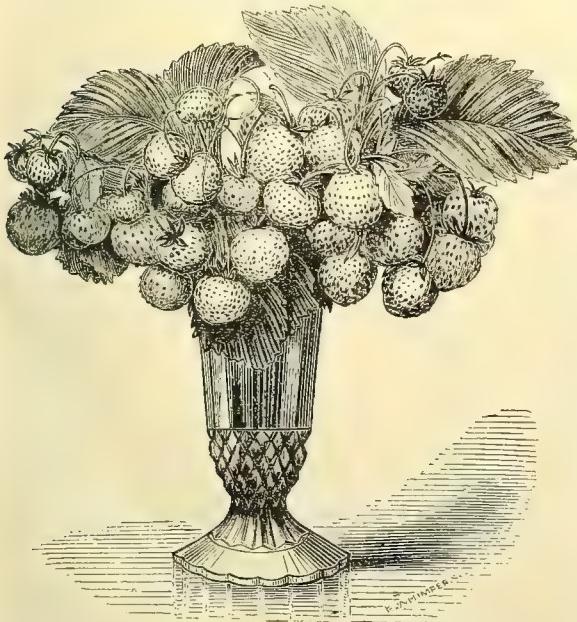

We have every season felt so much the want of water, that we would advise you seriously to consider all eventualities before you remove the garden from the neighbourhood of a good garden to a position where you will have no water except what the rains supply, or what you can carry by

various means. If, as you seem to indicate, the whole ground from north to south slopes to the south, then pipes could easily take the water from the pond to the proposed new garden. The birds will be a trifle after all in comparison with the serious drawback, the want of water.

If you decide on the removal, we agree with your proposed arrangements. Privet would make the quickest and densest fence. We would trench down the top-spit pasture as you propose, and would not think of dissipating its valuable properties by burning. Burning pasture land can only be recommended when the grass has become of a hard un nutritive character, and when the remains of the burnt heaps would, when spread over the fresh-tilled soil, do much to promote a fresh carpet of sweeter and more nutritive herbage. Unless your old Asparagus-bed has a number of young plants in it—that is, from one to three years of age, it would not be worth while to move any of them. You may get nice two-year-old plants for no great sum. For ourselves, we prefer sowing thick, say this March of 1864, and planting them some 3 or 4 inches apart in 1865, when the shoots are about 2 inches high, and taking means to prevent a root or rootlet from being injured. We think the simplest way for growing Asparagus is to trench and dress the ground well in winter, and before planting time to throw it into shallow ridges, say 27 inches apart, level the crest of the ridge a little, place the roots of the Asparagus over it fan shape, cover with the soil, water, and then mulch with rotten dung. After trying many plans we like this better than beds. A little salt and fresh mulching every summer will be sure to benefit the Asparagus, and there will be little risk of rotting from damp.

The sooner you break down the ground the better, but go little beyond the staple. You may stir the bottom of the trench and leave it. The subsoil is best incorporated by only raising a few inches at a time.]

RIVERS'S ROYAL HAUTBOIS.

We have already (p. 11) recorded our high opinion of this variety of the Strawberry; and we return to it for two reasons, of which the first is that we received a photograph, of which the above is a copy, with the following note relative to the discovery of the variety.

"I am perfectly charmed with the Royal Hautbois Strawberry; its clusters are enormous, and its fruit delicious. Its discovery was as follows:—In a bed of a thousand seedlings raised from Belle Bordelaise, and which seemed such a mass of foliage as to leave no hope that the shy-bearing

sort would give any variety, two large clusters of fruit were espied. The plants were carefully taken up and planted out as Nos. 1 and 2. The latter failed the next season, and was bad in character; but No. 1 was so fine that we named it the Royal Hautbois, and well it deserves its name."

Our second reason for recurring to the subject will be found in this extract from a little note on perfumed pink paper, the handwriting on which is always recognised with pleasure. "What could have induced our old forefathers to call this Strawberry Hautbois? It is French I am sure; but Deep (haut) and Bois (forest) neither describe the plant nor its dwelling, for the Hautbois does not delight in shady places."

This note reminds us of Scott's lines—

"So each mortal deems
Of that which is from that which seems."

inasmuch as that Hautbois is only a corruption of the German name for this species—Haarbeer. The first botanist we know who has mentioned it is Conrad Gesner, and he quotes a notice of it from Bock, whose works we have not seen. Tragus also mentions it, and states that it was found wild in Germany about Spires.

BEDDING GERANIUMS.

To treat of this subject more clearly than has already been repeatedly done by the able contributors to this Journal is a very difficult task, and it is rather with a desire to please than because there is a necessity for an article on the subject, that I give a somewhat lengthy reply to "J. H. K.," who, I hope, will find in it that clearness which he desires.

Presuming that a greenhouse, a cold frame, and a sheltered situation are at command, there will be no difficulty in raising any quantity of Geraniums; but all admirers of Geraniums have not these conveniences at command, and some have only a frame, and sometimes not even that, and the room windows have to serve for a greenhouse. To those whose means are limited I gladly devote this paper, convinced if it be the means of adding but a plant more to enliven the flower garden and gladden some heart, that my labour will be well rewarded.

Any time in July after the beds become furnished cuttings may be taken, selecting such shoots as run one over the other, and which would, if left on the plants, either crowd the bed too much, or be useless from becoming straggling, or being hidden by the foliage of the others. Judiciously thinning the shoots materially adds to the appearance of the beds, of which the beauty consists quite as much in the evenness of the plants as in their fulness of bloom. Before, however, any cuttings are taken, the surface of the bed should be completely hidden by the foliage, and when this is accomplished preparation may be made for propagating a stock of plants for another year. In taking cuttings let it be done so that an observer who does not see the operation performed could not tell that a cutting had been removed, and this can only be done by taking them from that part of the bed which is the most dense. In this way a dense overgrown part of a bed is made uniform with the thinner parts, in which, it is hardly necessary to remark, gaps should not be made by taking cuttings from them. In any case the plants will furnish cuttings by the beginning of August, which is a good time to commence providing for another year.

Having made choice of a young shoot with a growing point and two leaves or joints below it, cut it from the parent with a sharp knife a little above the lowest leaf, making the cut in a slanting direction towards the leaf, and when a number of these shoots have been taken cut each transversely through immediately below the lowest leaf, trimming off the two lowest leaves close to the stem, and the cutting will then have a couple of leaves or so and a growing point. The best cuttings are those having short joints, or the leaves near one another, and a top likely to branch immediately without any stopping. About half the cutting, say it is 3 or 4 inches long, should have the leaves trimmed off to form the future root portion of the plant, and on the other half the leaves are retained, and down to these the cutting is to be inserted in the soil. There are shoots the joints of which are often 2 or 3 inches or more apart. It is not necessary to insert more than one joint of such as these in the soil, re-

faining a rather large leaf with the growing point above it, nor is anything gained by putting in extra-sized cuttings. Those shoots with three joints, or at the most four, are far preferable to those with six joints. If the shoot have two joints with the growing point it should be cut with a sharp knife immediately beneath the lowest leaf, and that leaf being cut off the cutting is all that could be desired; but if the cutting be no more than 3 or 4 inches long and have three joints with the growing point the two lowest leaves may be displaced, and the shoot be cut transversely under the lowest. The cuttings ought never to be taken from bad-habited sickly plants, otherwise they are likely to partake of these defects, but from those which are healthy and well constituted.

Though there is but one way of making shoots into cuttings, there are several methods of treating them afterwards in order to induce them to strike root. The best is to pot them singly into 60-sized pots, in a compost of loam one-half, leaf mould one-fourth, and river sand one-fourth. Silver sand is preferable to river sand, but not indispensable, for Geraniums will strike almost in any way if one end of the cutting is put in the soil. We place a rather small crock so as to lie flat at the bottom of the pot and cover the hole, and on this the least touch of moss or sphagnum, or the rougher part of the compost; we fill as many pots as we have cuttings with the compost, which should be sifted through a half-inch riddle or sieve, place a handful in each, then press it gently down with the hand, and strike off all above the rim of the pot with the open hand. The next process is to make a hole in the centre of each pot with a dibble, and, with the cutting in the left hand, we take up a pinch of silver sand between the thumb and fore-finger of the right hand and drop it into the hole; the cutting is then inserted in the hole up to the lowest leaf, and a little more silver sand is placed around the cutting on the surface of the pot. A run round the compost next the pot fixes the cutting firmly, and secures space for watering, a gentle tap on the bench completing the operation. We have now cuttings with their bases surrounded by sand, and not one will fail to emit roots and be a plant in fifteen days if placed in a greenhouse in a moist shady place, and the soil about them kept moist, but not wet, for too much moisture is quite as injurious as too little.

When well rooted the cuttings, or rather young plants, may be potted into 48-sized pots, and placed in a cold frame for a week or ten days until established, when they should be placed out of doors on coal ashes in a sheltered situation, and the point of each shoot nipped out at the third leaf. By the beginning of October they will be strong bushy plants if duly supplied with water, and as it is not safe to keep them outside any longer, they should be taken into the greenhouse, placed on shelves near the glass, and have abundance of fresh air daily in mild weather, and water once or twice weekly as occasion may determine, but none to be given until the soil becomes dry. The temperature should range from 40° to 50°, fire being only employed to prevent the mercury from falling below 35° at night. Air must be given when the thermometer reaches 45°, and the house should be shut up with a temperature of 50°.

In February the plants will be furnished with four to six shoots, each of which will in all probability furnish a cutting, which, if there be the convenience of a hotbed, may be taken and struck; and these cuttings furnish nice plants by bedding-out time, and though small, afford a fine bloom late in the season. Such cuttings may be inserted either singly in 60-sized pots, or round the sides of a pan or pot, and being placed in a Cucumber-frame, they will be well rooted in about a fortnight or three weeks. They should then be hardened off by placing them in the greenhouse, shifted into 48's by the middle of March, and placed on a shelf, where they should be duly supplied with water, and have the points of the shoots pinched out in the beginning of April. If the cuttings are inserted round the sides of pots or pans, they should be potted off in March into 48's, and have the points of the shoots pinched out when the roots have taken good hold of the soil. These will be stiff nice plants by the beginning of May, when they should be hardened off in a cold frame for a week or so, and then removed to some sheltered situation where they can be protected with mats placed on hooped sticks should severe

frost occur. Though nice "stuff," such plants are not equal to those struck in autumn, nor do they flower so well as older plants; but they are, nevertheless, very useful when the stock is short or the supply of autumn-struck plants not sufficient to fill the beds or parterres.

The autumn-struck plants in 48-sized pots, from which the last-named plants are taken, should be potted in the beginning of April into 24-sized pots. They will grow rapidly, and in ten days after potting may be removed to a cold frame, where, by covering in frosty nights with mats, and with due regard to giving air and water, they will by the second week in May be strong, dwarf, bushy plants, some of them more than a foot through, and for the most part coming into bloom. After a fortnight's exposure in some sheltered yet open situation they may be planted in beds, where they will at once produce an effect of which any gardener may be proud.

Now this system, I may be told, requires considerable house-room to carry it out. This is certainly true; but the extra size of the plants and the immediate effect they produce is worth the room and trouble; and those who try this plan against the ordinary methods will, I think, find one of the plants cover something like four times the surface, so that one-fourth of the number of plants will do the same work, give a greater effect, and fully a month or six weeks earlier than late autumn or spring-struck plants.—G. ABBEY.

(To be continued.)

SMALL LOCAL SCIENTIFIC SOCIETIES.

We should have very little difficulty in collecting the names of five hundred societies having for their objects some improvement or the acquirement of knowledge of various productions of nature. These objects are multitudinous, ranging from the growth of a large Gooseberry to the acquirement of a flora or fauna of all the British isles. These societies are dotted about in every county, and each society is a centre from which diverge around it better habits, better tastes, and better knowledge. From time to time we publish what some of these societies are doing, and some of their doings in the report of the Bloomsbury Flower Show appear in our columns to-day; but we have a stout pamphlet before us which tells of still higher efforts, and evidencing still further advance in the pursuit of that kind of information which makes a man fonder of home, because there are his books and his other sources of pleasures which he finds are the only pleasures which have not their track traced by regret.

The pamphlet we have mentioned is No. 5 of "Transactions of the Woolhope Naturalists' Field Club." Now, very few of our readers, without a reference to their topographical dictionary, would be able to tell that this Woolhope or Wolhope is a village about eight miles from Hereford, one of the most lovely districts of England; and there amongst its quiet Apple orchards dwell many of the members of this Naturalists' Club; and not only is the Club flourishing, but the President, C. Wren Hoskyns, Esq., in his annual address, thus rejoices over the increase of such local associations:—

"I cannot, however, enter upon the duty of endeavouring to recall the proceedings of the Woolhope Naturalists' Field Club during the past year without indulging a reflection, which occurs to me very strongly, upon the great extension of interest which has taken place in these pursuits which form the out-door study and objects of societies like our own, and have led to their increased establishment in the surrounding counties and districts. Nothing, perhaps, in the year has been more remarkable than the evidence of this which it embraces in the growth of these kindred associations around us, and the joint meetings and augmented interests to which they have from time to time given rise."

"Beside the Malvern, the Cotteswold, and the Warwickshire Clubs, which we formerly recognised in the adjoining or neighbouring counties, we have now to welcome the restoration of the Dudley and Midland Geological and Scientific Society, the Severn Valley Field Club, the Oswestry, the Bridgnorth, and the still-more-recently-established Caradoc Club, occupying areas that well deserved the scrutiny of separate societies, while their establishment has increased

the opportunities of mutual acquaintance and united labour amongst the members resident in the different districts."

He then proceeds to remind the members of their various tours during the past year, of which chatty interesting portions we will only give one relish.

"The second meeting of the Society, which took place on the 7th of July at the Craven Arms, near Ludlow, was one that will be long remembered by those who were present. It was a joint assemblage, in fact, of not less than five societies, consisting of the Oswestry, the Dudley, the Bridgnorth, and the young and promising Caradoc Club, with our own. The place chosen presented several attractions—the ruins of Stokesay Castle, for the inspection of the archaeologist; the Wood of View Edge, said to be the only place in England where the *Astrantia major* is supposed to grow wild, of which abundant specimens were found, and to the judgment of some, rather cruelly brought away, suggesting to the mind of our late Secretary the very just remark, that 'it is not wise to talk too loudly about a scarce plant,' for several of our number who climbed the heights of the wood in search of it, came out of it with the rare *Astrantia* ruthlessly torn up, in some cases by the roots, and borne in ruinous triumph on their hats, and other parts of their dress. 'I took two specimens—for I do not like to exterminate'—adds his communication; but if all the septuagint of naturalists assembled on that day were equally forbearing, the exterminating process will hardly have received a very exemplary check.

"But the Wood of View Edge contained another attraction in its celebrated quarry of Aymestry limestone, where nearly the whole of the rock, exposed to a thickness of from 30 to 40 feet, is composed of *Pentameris Knightii* cemented together."

We pass through many such pleasant passages, until we come to the chief contents of the pamphlet, entitled "The Day at Malvern and the Mistletoe in Herefordshire." It is the work, the exhaustive work, of Dr. Bull, for very little relative to the Mistletoe is not here collected and recorded attractively. Here are detailed its mode of propagation and growth, the trees it lives upon in the county, the recorded instances of its growth on the Oak in England, and the romance of its history in times past and present. Gladly would we publish each of these sections entire, for they are full of interesting information; but we cannot afford the space, and must confine our further extracts to some from the notes on the Mistletoe on the Oak. Dr. Bull says:—

"The occurrence of the Mistletoe on the Oak is at once so rare and so interesting, that I have not confined myself to this county in my inquiries about it, but have taken some pains to ascertain its existence, at the present time, in all the instances which have been recorded as occurring in England. The following instances I have been able to get well authenticated:—

"THE OAK AT EASTNOE.—Ten days since, I visited this Mistletoe-bearing Oak. It is situated by the side of the drive leading from the park up the Ridgeway hill towards Malvern, about 200 yards beyond the lodge. The Oak may be some eighty or ninety years old, and the Mistletoe grows freely upon it. It is most luxuriant high up in the tree, where three large branches grow very near each other, having in each instance destroyed the bough beyond the place where it is situated. It is also growing in four other places in the tree, one fresh yearling plant shooting straight out from the main stem of the tree about 12 feet from the ground. One large bunch of Mistletoe growing in a large branch many feet from the main stem was dead and decaying, but without having killed the branch. The Mistletoe plants are of both sexes, and the females bear berries freely. It is more slender and pendulous, with smaller and thinner leaves; or, in other words, it is not so stiff and rigid, and short-jointed, as it usually is when growing on the Apple tree. During the twelve years I have known this tree the Mistletoe has increased upon it, and the Oak is already beginning to show signs of suffering severely from the parasite. Upon the large moss-covered branches it was curious to observe the great number of Mistletoe seeds which had been deposited by the birds."

Dr. Bull gives similar notices of specimens on Oaks at Tedstone Delamere; Badams Court, Sedbury Park, near Chepstow; Burningfold Farm, Dunsfold, Surrey; Hackwood Park, near Basingstoke, Hants; and the Plymouth Oak, by

the South Devon Railway. These are the only six instances which Dr. Bull has been able to authenticate; and he, as well as ourselves, will be much obliged by any of our readers informing us of other instances within their own knowledge.

WORK FOR THE WEEK.

KITCHEN GARDEN.

DIG in haulm, stumps, and the refuse of crops directly they are over. At this season there is seldom any ground to spare, for it should be remembered that the supply for several months in winter and spring will depend on the diligence now exercised in planting out as large a supply as possible of those vegetables most likely to be in demand. Potatoes and other crops soon coming off may be interlined with Broccoli or Winter Greens; and where there is not sufficient room, a quantity may be planted at 1 foot apart to remain till ground comes in by the removal of other crops, when the whole may be again planted at proper distances, or every other row and each alternate plant of the remainder removed to vacant ground. The above will answer well where the space is limited, more particularly for those kinds coming into use in spring. *Cabbage*, make a sowing of East Ham Cabbage for early spring use, and the last sowing of Coleworts. As soon as the caterpillars attack any of the Cabbage tribe, give them a slight dredging with white hellebore powder in the morning. *Celery*, pay strict attention to the early crops. Let it be gone over with the hand and all the offsets taken off, and, where practicable, let it have a thorough drenching with manure water, after which, on the following day, give a slight earthing-up to prevent evaporation. *Peas*, make a sowing of Early Frame; if the autumn is fine, they may be useful. *Shallots* and *Garlic*, when they are ripe take them up and hang them in bunches in a dry shed previous to placing them in store for use. Make a sowing of White Stone Turnips.

FRUIT GARDEN.

The tendency to excessive luxuriance frequently exhibited by espalier trees, renders the operation of stopping and shortening shoots more particularly essential. The whole principle of pinching is merely this—in the first place to pinch all young shoots not necessary for the framework of the tree; secondly, to stop those shoots which threaten to overgrow their neighbours, by which means a due equilibrium of the branches will be maintained; and, finally, having commenced a system of repression, to continue it in regard to the lateral shoots which are developed by reason of this system of stopping. When time will permit, *Currants*, *Gooseberries*, and *Raspberries* will be benefited by the remaining wood of the present year's growth being thinned, leaving only sufficient to furnish next season's crop. Strawberry-runners that were laid some time ago in three-inch pots are now ready for shifting into five-inch ones. For this purpose use a compost of two parts friable yellow loam and one part of well decomposed dung. Take care that the pots are well drained, and have them placed in the south aspect, and on boards or slates raised a few inches above the surface of the ground to prevent the worms getting into them.

FLOWER GARDEN.

Climbers on walls to be attended to as they advance in growth, keeping the young shoots neatly tied-in, &c. The climbing Roses will also require to be gone over occasionally for the purpose of cutting off decayed blooms, and any weakly old wood should be cut out at the same time to allow of laying-in the strong young wood which will bloom much finer next season than the old wood would do. Any of the Perpetual Roses that have flowered very freely, to be assisted by a liberal watering with manure water from the stable or farmyard-tank; indeed, too much of this can hardly be given to any of the autumn-flowering varieties. Carnations and Picotees will require copious waterings during the present dry weather. Earwigs are extremely destructive to this class of flowers by eating off the lower part of the petals. It is usual to trap them in tobacco-pipe heads placed on the tops of the sticks which support the plants. These, however, must be new, for if they have been smoked with the smell of the tobacco will prevent the earwigs entering and thus defeat the object in view. As the seed-pods of Pansies ripen they should be gathered, and dried in

a shady place. Commence the layering of Cloves, Carnations, Mule Pinks, &c., of which there is rarely an overstock.

GREENHOUSE AND CONSEERVATORY.

Specimens that have matured their season's growth should now be more sparingly supplied with water at the root, in order to promote the ripening of the wood. Orange trees or other plants known to be liable to the attacks of red spider must be frequently examined for this pest, and well washed with the engine immediately it is perceived, taking care not to bruise or injure the foliage, and placing the affected part so that every leaf may be reached. In keeping up a stock of plants there must necessarily be, besides those depended on for the principal show of bloom, younger branches of the same family, which are growing onwards to supersede their seniors whenever old age or decay shall consign the latter to the rubbish-heap. Such plants as Epacries, Leschenaultias, Pimeleas, Aphexes, and others of the same habit, which have been kept for late bloom and are now over, should be placed in the house with a north aspect, or in deep frames or pits with the sashes turned towards the north, having first picked off the old remaining blooms. Here, with a gentle syringing once or twice daily, the plants may remain till a new growth commences, when any pruning they may require may be given; and they may afterwards be placed in more favourable positions for ripening their wood.

STOVE.

Admit more air into the house as the season advances, because, although this is the period when every advantage ought to be taken of heat and light, still the confinement of the stove is apt to draw the plants, especially if carried out late in the season. Growth is now required in most kinds of plants; but the great art is to harden or perfectly mature that growth, or the plants will suffer much during the winter. Many of the plants in an advanced state may now be placed in the greenhouse, which should be closed on cold nights. A number of Orchids will by this time have made their growth, and may be removed gradually to a drier and cooler atmosphere. Those which still continue growing must have the syringe two or three times a-day, and a humid atmosphere must be maintained by well watering every part of the interior. At the same time plants growing on blocks or suspended in baskets should be frequently soaked.

COLD PITS.

The stock here will probably require re-arrangement at this time, as some of the specimens, having completed their season's growth, will be better in a shady place out of doors, and their removal will allow of giving more space to those left. Young growing stock and late-flowering plants that have yet to make their season's growth should receive the most careful attention, as, if well treated, they will make rapid and vigorous growth at this season, and nothing in the way of good soil, careful potting, or proper accommodation will compensate for the want of this. Indeed, there is no possibility of securing free growth from hardwooded plants in bright hot weather, except by moderate shading and maintaining a moist atmosphere by sprinkling the plants overhead morning and evening, and air must be given liberally to keep the wood strong, avoiding as much as possible exposure to drying winds.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

ON the 17th we were favoured with a thunder shower, which revived vegetation with us wonderfully. As usual, we on the height had but little of it in comparison with those in the valley; but we are thankful as we were fast getting out of water. Our first and second Marrow Peas were fast ripening, and, besides mulching, we were helpless as to prolonging the season by other means. The shower gave us some hundreds of gallons in our tanks, but before it came, in our chief reservoir for supply we did not have a couple of hogsheads. But for our sewage tank we must have been very badly situated, and had the mortification to see plants dying without the possibility of helping them. As it was, we could only single out the plants that showed signs of suffering. The excessive heat of the week has pretty well evaporated all that the thunder shower gave us, but it

came at the right time, and there are signs that it will not be long before we have another refresher.

We never saw corn crops looking better in this neighbourhood, and the warm rain of the 17th would do much to swell out and give substance to the grain. Some neighbours, indeed, grumbled that there was not enough of moisture for the Turnips; but it is the nature of some people ever to be looking for causes of complaint instead of reasons for thankfulness. We believe, however, that in nine cases out ten this grumbling is more a matter of habit than of feeling. The grumble is the safety valve that gets rid of the noxious pent-up steam, and leaves behind it the sturdy, kind, large-hearted Englishman. Let even the go-a-head politician have his grumble out, and it will generally be found he will be the last to seriously think of leaving the shores of old England. Grumble or no grumble, the summers of 1863 and 1864, in this part of the country (Hertfordshire), ought to show the importance, especially in the case of contemplated gardens, of making a water supply a matter of primary consideration. We have known of some cases where great expense was incurred in making a garden before a supply of water was taken into consideration. A good position and a good soil, the very things for general field crops, will not be sufficient for succession crops in a garden without water being at command. Even when water can be had, but must all be conveyed by pail or barrel, the labour of applying it is very great when compared with that involved when a reservoir of water can be had in so elevated a position that by means of taps in the garden and a long hose, any part may be flooded at will. Whatever the primary expense, such gardens, so differently situated, cannot justly be compared as to the necessary labour power.

We agree very much in almost everything advanced by the writer of the article from the "Scottish Gardener," at page 52. We demur, however, as to the mode of contrasting the value of the produce from the garden of a gentleman and the produce from a market garden. In the latter case quick returns and a quick clearing of the land for another crop must be the chief objects. In the former case a constant successional supply must be the great aim. The cartloads of early Cabbages, Cauliflowers, Lettuces, &c., are what pay the market gardener. Such loads of stuff in a private garden would be of little use, unless to give the establishment a distaste for vegetables for months afterwards—a thing the gardener ought to guard against, instead of attempting to promote. True, such produce might be sold; but here again, the very isolated position of the majority of gentlemen's gardens, which of itself gives an enhanced value to vegetables and fruit obtained fresh and at hand, would often render the attempted sale a matter of anything but profit, from the absence of, or the distance from, a market. The different circumstances demand a different estimate of the value of produce. So much is this the case, that we know instances of first-rate gardeners declining the offer of a gentleman's large kitchen garden in the country, merely for the keeping it up, and without any rent, and go to the neighbourhood of a town, and make money there, though they paid from £5 to £8, or more per acre for their land. They were wise enough to know that, the establishment having left for some years, they could not procure manure for the garden, and even if some were obtained, that then they might look in vain for customers for the produce. If the garden were very large, they might manage by looking after the fruit, and throwing all the rest of the ground into Potatoes and grain crops, not otherwise.

The very circumstances, therefore, that enhance the value of garden produce in the country above that which obtains at Covent Garden, would just so much lessen its value if you were forced to turn it into a marketable commodity. We quite believe gentlemen when they tell us that they could supply their servants cheaper with vegetables from Covent Garden than from their own garden. This must be the case even on the division-of-labour principle; but we as thoroughly believe them when they tell us that for their own use there is no comparison between that bought in a market and that grown in their own garden, so far as richness in flavour is concerned. This would be still more seen if a more simple system of cooking became fashionable. A satirist has told us that flint soup is a capital thing, if the flints are well boiled in some rich gravies, and stock liquor.

Cauliflowers, Peas, &c., are so overdone with cream, melted butter, and sweets, that the original flavour is lost. Some people would actually experience the pleasure of a fresh sensation could they partake of a nice sweet Cabbage simply well boiled with a grain of carbonate of soda in the water. Having everything, therefore, fresh, in good order, and in constant succession, ought ever to give a value to the produce of private gardens above that for which it can be bought in such markets as Covent Garden, as the bulk of the providers there study quick returns, rather than constant, regular successions. Where private gardeners are expected to sell, they soon fall into the market-garden system, and instead of a little of this and a little of that at a time, they give up growing in rows, and grow in quarters and acres, clear the ground at once, and begin again—a good plan where there is a ready market, but a poor plan when a family must be supplied well every day. After all, even at general rates, we have met with few kitchen and fruit gardens which would not pay their expenses well where there was a family to consume the produce.

The great difference between the private garden and the market garden is just this—that the latter is exclusively a matter of profit and loss; the former is greatly a matter of pleasure. Gentlemen are apt to draw the comparison, looking merely at what comes to the table, and thinking nothing of what merely gratifies the eye. In many cases pleasure grounds and flower gardens cost two-thirds or three-fourths of the outlay, and no profit in general can be derived from them except pleasing the sight. Nothing is so expensive as a well kept lawn. You go over it at least once a-week, and it is only nice after all, yielding nothing but pleasure to the eye. It is a little strange, that in most small new places, the really useful parts—the kitchen and fruit gardens—are curtailed as much as possible, and as much room as possible given to pleasure ground and lawn. And then there is nothing more common than for the proprietors of such gardens to look at the sum total, and then tell their friends somewhat confidently, that every Cauliflower that comes to table, and every dish of Strawberries, and every bunch of Grapes must cost little less than this or that, when the whole of the eatables put together may have cost little more than a tithe of what was spent for mere pleasure and appearances. Take these things out of the way—allow something for freshness and quality, produced by regular successions in fairly managed private kitchen gardens, and then, even on the point of value received, there need be no fear of competition with market gardens.

We have nearly finished the third successional lot of Cauliflower, the great heat causing even some of the fourth lot this season to show rather prematurely. Watered the fourth and fifth successions with sewage water, and covered the ground with short grass and litter, to keep the heat out and moisture in. The sixth and seventh successions, planted among other things, would merely have a little clean water, as they are not established enough for stronger doses as yet. Watering when we could obtain any, and mulching and shading when we could not, have been the chief work in the kitchen garden. In some of the hottest days, we just spattered frames and houses of Cucumbers, &c., with a little whitened water, which prevented evaporation going on so rapidly as it would otherwise have done.

FRUIT GARDEN.

Much the same as in previous weeks. The flowers of sulphur daubed against the back wall of the orchard-house has pretty well done for the red spider where it had appeared. Plums are now coming in, and are useful from pots at present. Some ants had attacked a few of our best Cherries. The fruit touched were carefully gathered and removed. A little guano was strewn along the ground, and especially close to the foot of the wall, and well watered with manure water. We have seen no ants since. If something of the sort were not done we should expect them to lodge in the Peaches, &c. A good watering of lime water will generally have the same effect. If the ants are not killed they will be sure to take themselves away to other quarters. When fruit trees on the open wall are infested with ants, earwigs, &c., a good plan is to lash the wall well with clear lime water, which will tend to bring the most of them to the ground, and then run a line of paint, say 4 inches wide, along the bottom of the wall, the paint con-

sisting of equal parts of oil and tar. The oil prevents the tar hardening quickly, and so long as it is soft nothing will pass over it.

Removed all coverings from viney-borders, so that these might have all the benefit of the bright sun to warm them. This was done on Monday last. When we expect a shower we will throw a dusting of superphosphate over the surface. If no rain come soon we will give a manure watering. Had the week been cold instead of hot we would have thrown some litter over the border to keep the heat in, raking it down when the sun shone.

Figs in our little house are rather too plentiful. We let them pretty well look after themselves. Our plants are as rough-looking as rough can be, but then they always bear well. Not to speak of others in pots in the orchard-house, we have two small plants of that honeydrop Fig the White Marseilles, of Mr. Rivers's fertile variety. We used to grow the common Marseilles, the fruit equally good; but then, do as we would, we never obtained a good crop of them. Mr. Rivers told us that there were two distinct varieties, the one always shy in bearing, the other always very productive. We find this to be the case. The second crop is now ripening, and there is a heavy succession of smaller ones for the third crop. The flavour of this Fig is delicious when cracking and showing its rich globules of juice. For a sure supply, however, nothing beats Lee's Perpetual or the Brown Turkey, as we believe them to be identical.

This is just the weather for fine Melons. Lest they should be prematurely ripened by a fierce sun, it is well to shade slightly for a few hours at the hottest time of the day, and give air plentifully, and especially give it early. In such weather as last week, air all night would be desirable, and the sashes should be freely tilted by six or seven in the morning. When the weather changes our practice in this respect must also change. Meanwhile, we may state as a secret which we cannot keep, that many mishaps under glass are the consequence of giving air too late. If air is admitted early there is no chance of steaming, scalding, scorching, or burning, as the house heats gradually, and the ventilation and the sun's rays together keep the enclosed atmosphere in motion. When the house is opened after the confined vapour has condensed on fruit, &c., the free opening will do as much harm then as keeping the house shut. In such misadventures very little air should be given at first, and the floor kept moist, and the house shaded, until the usual healthy state of things is restored.

ORNAMENTAL DEPARTMENT.

The dry weather has reduced mowing and machining the lawns to a minimum. The chief care has been to keep plants in flower-beds alive by giving a drop of water to those flagging, and mulching others with a little leaf mould or very rotten dung, as stated last week; we would give more if we had it. By such means we have as yet kept flower-beds and borders in fair condition. We have given sewage and other manure water to Dahlias, and would have done the same to drooping herbaceous plants if we could have afforded it. Hollyhocks would also have had such help, as without it the spikes will be dwarfer than usual; whilst, in our opinion, other things being equal, the taller the spike of a Hollyhock, the more majestic it will be.

The rain on Sunday gave a good opportunity for sweeping walks, and rolling them firm on Monday morning. It came so gently that even florists' flowers of all kinds, as Pinks, Carnations, and Picotees, were greatly benefited. The hot weather is so trying to Carnations that a slight syringing of an evening would do them much good, even when watering is not desirable. Syringing such plants as Brugmansias out of doors on evenings when the atmosphere was cloudy after a hot day, also did much good to them, refreshing them very much. When the sky promised to be clear at night, the almost sure free deposition of dew did away with the necessity for syringing. We have had beds of Calceolarias, very languid at night, but all right in the morning, as every leaf and spray was loaded with dew. Picotees and Carnations, of the best kinds, may now be layered; Cloves and Carnations, of the commoner kinds will strike freely by cuttings, with a little bottom heat, and cuttings may be obtained when the shoots are too short for layering. The cutting is easiest made by catching the lower part of the shoot with one hand so as to steady it, and then, taking hold of the top of the shoot with

the other hand, pulling it out at the second joint with a sudden jerk. Generally it will come out so clean and nice, that no cutting across with a knife at a joint would equal it. The cutting needs no more making, unless a little film should be left remaining. Pinks may be more easily propagated the same way; and at this early season they will soon strike in sandy soil under a hand-light; provided it is shaded during the hottest part of the day, and a little air given at night. Carnations strike better when there is a little bottom heat below the light soil on which the hand-light rests. Early Pansies may now be struck in a shady place, or the old plants be divided, or seed collected from favourite kinds. Those in full bloom would like plenty of water and rich mulching, and then they will keep on through the autumn. Dahlias at all forward will need tying, thinning of shoots and foliage, and traps used for earwigs, &c.

No weather could be better for hardening the shoots of Pelargoniums that have finished blooming. If the weather be very hot and dry it will be advisable to water the ground on which the pots stand without watering the surface soil of the pots. Plants blooming and those coming on in succession will want plenty of water. Make sure that the water goes over the whole surface soil, instead of making a hole close to the stem of the plant. Fine plants are thus injured and destroyed by gangrene, mouldiness, &c.

Such hardwooded plants as Heaths are best kept in this weather under frames, with the sashes facing the north, and air on not only at top but also beneath the bottom of the frame all round. Epacris may now have plenty of sun to ripen the wood, as the flowering greatly depends on that. All potting should now be rather moderate as respects shifts, in order that the pots may be filled with roots before the end of autumn. Large shifts should only be given at an early part of the season when the whole summer is before them. The same rule holds good even with stove plants.

When greenhouse plants are placed out of doors all those with fine hair roots, and all that are at all tender should have the pots protected from the fierceness of the sun, even although the head of the plant should be fully exposed. Such plants demand careful watering, or insects or death will be the ultimate consequence.—R. F.

COVENT GARDEN MARKET.—JULY 23.

The market continues to be well supplied notwithstanding the dry weather which prevails. Pines, Grapes, Peaches, and Nectarines, are both good in quality and sufficient to meet the demand. Heavy consignments continue to come in from abroad, and comprise, among other things, Apricots, and Green Gage Plums. Good Jargonelle Pears are sent in from the Channel Islands, and there are now also some of home growth. Raspberries will soon be over, and Strawberries are getting scarce. Green Walnuts, for pickling, are bringing from 6s. to 10s. per bushel.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

GRAVES SHRIVELLING (*J. D. D.*).—Well they may on a sandy soil, and the temperature often 105°. As the crop is so heavy give weak liquid manure once a week; water abundantly; mulch the surface with cocoanut fibre refuse an inch deep; give air more freely, and leave the ventilators open at night during this very hot weather.

LEECH-LIKE GRUB ON PEAR LEAVES (*C. P.*).—It is the "Slimy Grub" in the gardener's vocabulary, and the grub of the Selandria athiops, or Pear Saw-fly of entomologists. Dusting with slaked lime destroys them.

GRAPE (*H. F.*).—The three bunches of Black Prince Grape exhibited by Mr. Hill, Keele Hall, Staffordshire, weighed 13 lbs. 10 ozs., and were not "bunches" weighing 13 lbs., which is the rendering of your note. Great credit is due to Mr. Hill, who, by his skill and perseverance, has succeeded in accomplishing such extraordinary feats in Grape growing. If you will refer to Vol. V., p. 234, you will find, in a notice of the gardens at Keele Hall by Mr. Fish, some valuable information relating to the means at Mr. Hill's command; and when we add to these his well-known skill in Grape culture, we arrive at the conclusion that such enormous bunches are produced by superior vineeries and superior management. If you wish to equal such you must provide the same means, and bring an equal amount of skill and perseverance to bear on the cultivation of the Vines.

STOPPING CHRYSANTHEMUMS (*Dorset*).—It is not safe to stop the large flowering Chrysanthemums after July, and Pomponies later than the first week in August, and this will make the blooming late.

SHALLOTS AND ONIONS MAGGOT (*H. S. C.*).—They are suffering from grubs, which eat into them and cause a mouldiness at the root. The moment marks of their presence are observed the beds should be watered with strong lime water made by placing half a bushel of quicklime in a hogshead and pouring water upon it, and adding half a bushel of eot. Allow this liquid to stand twenty-four hours, then water the beds with it. Soot water is such a stimulating manure that it is advisable to water the crop of Onions whenever dry weather occurs—that is, when the Onions are growing; and if applied sufficiently early, or before the fly deposits eggs, it is a good preventive.

ROSES AT CHRISTMAS (*Ignorantia*).—If the Roses that were forced early are strong, and the wood well ripened, they will answer the purpose. They should now be cut down to four eyes and plunged in coal ashes on the north side of a wall; but prior to this they should have been potted in June, and have been brought into a state of rest by withholding water. They will require copious supplies of water and frequent syrings overhead whilst on the northern aspect, where they may remain until the last week in September, when they should be placed in a cold frame or pit. By that time they will have made new growth, and must be kept clear of insects and have air daily, with protection on cold frosty nights. Early in November remove them to a house with a night temperature of 45°, with a rise of 10° to 15° by day with sun and abundance of air, increasing the temperature so that it may be 50° by the beginning of December. These plants may probably furnish blooms at Christmas if the precaution be taken to retard them if too early, or forward them if too late by placing them in a higher temperature. The most certain method of having Roses late in autumn up to Christmas is to grow a selection of the best Hybrid Perpetuals, in pots in a cold frame, and after they have bloomed in summer to cut them down to four eyes, or, if young plants, they must not be allowed to bloom, but have the blooms taken off, and be cut back to from four to six eyes by the 1st of August. If duly supplied with water, and the lights kept off until October, they will, for the most part, be showing finely for bloom at that time; and the lights should be drawn down in mild weather, but replaced in wet weather. In frosty nights a protection of mats will be necessary. They will come into bloom late in October, and the latest being removed to a greenhouse in November, when the bloom buds are about the size of a marble, will flower in about six weeks. A temperature of 50° is necessary to secure the expansion of the flowers.

BOOK (*J. Smith*).—Mr. Mills "On the Pine Apple" gives the usual culture in pots. Hamilton "On the Pine Apple" details his mode of culture by planting out.

PLUM TREES BLIGHTED LAST YEAR (*Ada*).—Having lost their leaves last year they were unable to make growth so as to bear this year, but being now vigorous they will be fruitful probably next year. Mulch over their roots to keep moisture in the soil during this very dry weather. Send five penny postage stamps with your direction, and order "Fruit Gardening for the Many." It will go free by post, and contains full directions on the subjects you name.

CLOVER SEED (*B. H. W.*).—What you state does not alter our information. Our quantities were taken from official returns. It is quite true a small quantity of Clover seed comes from France and the United States, but the quantity is not specified, but is included in the totals we printed. We stated that Cambridgeshire is the county where the home-growth of Clover seed chiefly prevails; and the other counties you name are all in the area we characterised as being mild and with a small rainfall.

GREEN GAGE UNFRUITFUL (*P. Q.*).—Being on a wall having a north aspect, and having no sun shining on it until 4 o'clock, is the cause of the unfruitfulness. The wood does not ripen sufficiently to produce perfect blossoms. The Magnum Bonum is a harder variety.

BLOTTCHED ROSE LEAVES (*An Old Indian*).—The brown blotches are caused by want of moisture at the roots and the dry heat of the wall. Liberal syrings, a gallon of water to the roots of each tree every evening, and mulching over the roots to keep the moisture from evaporating, will be your best treatment. Cut away the great sucker without mercy.

WEED ON LAWN (*S. J. C.*).—It is *Prunella vulgaris* or Self-heal. It will be injurious to your lawn, and we recommend you to employ a few women with old knives to root it out.

GOOSEBERRIES, CURRANTS, AND RASPBERRIES IN A KITCHEN GARDEN (Reuter, Kent).—We expect an article from one of our contributors on this subject; but in the meantime we may say that in most small gardens, and in some of considerable size too, the old-fashioned mode of planting Gooseberry and Currant trees in borders by the side of walks has many advantages, and the space between the trees and the edging may be occupied by any low-growing crops, and not unfrequently by flowers. Raspberries, however, had better be planted in the coolest part of the garden, and if it is a little moist they will do all the better. Black Currants also like a cool soil, although they do well in one of a contrary description. Of the varieties of these fruits, the best Black Currant we have grown is Black Naples. The Red Dutch and Wilmot's Red are both good, and so is Ruby Castle, which ripens late and bears well. The White Dutch is as good as any White variety we know. There is a pale red or hybrid kind called Champagne, admired by some. In Raspberries, Prince of Wales is a stronger grower than the Fastolff, although the latter excels it in size of fruit. The Double-bearing is also useful; and the White Antwerp is of use at table. The varieties of Gooseberries are infinite, and it would be difficult to give advice on this head without knowing which was wanted; but in general we may observe that the small kinds are better flavoured than the large ones. The old Turkey Red, called in some places Champagne, is hardly excelled anywhere; neither is the Green Gage, but these do not fill a basket so quickly as the larger kinds. The large white and green kinds are very prolific, although none are more so than the old Rough Yellow, called Yellow Lion in the London markets. Generally speaking, the darkest reds are most admired for preserving, and the colour is much improved when they are grown in the full sun. The Warrington is much used for preserving.

RHODODENDRONS, WATERING, &c. (S.).—As you have commenced watering your Rhododendrons you must continue doing so until heavy rain falls, after which the moisture in the atmosphere will preserve them for a few days, and they will more gradually and naturally ripen their shoots. To leave off watering in dry weather after having continued it some time is bad practice. If the short grass upon your beds does not appear unsightly, you might let it remain until later in the summer, as it will assist in retaining the moisture. If the soil be stiff, digging in sand that is not impregnated with injurious mineral matter will be beneficial. Generally speaking, drift sand from a road or river (not a tidal one), is better than pit sand, but whatever is added to Rhododendron-beds must be only worked in within 2 inches of the top where the roots are, and most likely with the watering and shading you have given the roots are near the surface. We are glad to hear you report so favourably of Rhododendrons so near the city, and we hope your plants will continue to prosper. We should certainly prefer digging in sand rather than short grass, especially after the latter had lain so long as to become little else than useless litter.

SEEDLING VERBENA AND TROPOEOLUM (G. C.).—Your Verbena appears to be quite novel in colour among the striped section of this flower and is a very pretty variety. It would form a nice contrast with *Striata perfecta*, but we can tell nothing of its value unless we are informed of its habits. It is very hazardous to decide on the merits of a Verbena from two or three perishing trusses. Send up a plant to the Floral Committee. The flowers of the Tropaeolum were quite shrivelled, but judging from the faded flowers the colour did not seem new. The only way to discover its merits would be by seeing a plant under good cultivation.

WIRE EDGING FOR BEDS (Sacerdote).—We think wire edgings no ornament to beds on grass, for they are there without a meaning, and serve no purpose beyond that of making the flowers appear as if confined in a cage. The effect, however, is good if the wire be covered with some creeping plant, as Gold or Silver Variegated Ivy, or Ivy-leaved Geraniums, and the bed itself filled with bedding plants. The following are examples of such an arrangement:—Wire edging, *Cineraria maritima*, *Lobelia speciosa* planted inside it, forming a ring round a centre of Scarlet Geraniums; or *Tropaeolum elegans* might be trained over the wire, then a ring of *Cineraria* round a centre of *Perilla*. Other arrangements might consist of *Cerastium Biebersteinii* on the wire, then Scarlet Geranium, and a centre of *Yellow Calceolaria*; or you might have Gold Variegated Ivy on the wire, then a ring of *Cineraria*, and a centre of *Lobelia*; or Silver Variegated Ivy on the wire, and a bed of *Calceolaria*, Geraniums, or other bedding plants, not being those with silvery foliage. Again, *Lonicera brachypoda* variegata, *Mikania scandens*, *Cobaea scandens* foliis variegatis, *Maurandya alba* and *Barclayana*, *Antirrhinum lindernifolium*, *Nierembergia gracilis*, *N. intermedia*, *Verbena* (sorts) *Linaria cymbalaria*, *Lysimachia numularia*, *Petunias*, and *Nasturtiums*, are all well adapted for covering the wirework, and you may then fill the basket with any kind of plant that will contrast with the edging plant. We are not in a position to express an opinion on the plants you name as having handsome foliage for the flower garden. By-and-by we shall take up the subject and give a list of the plants with the most effective foliage for the decoration of the flower garden. An account of the Birmingham Rose Show appeared in No. 172, page 27.

HOLLY HEDGE UNTRIFLTY (C. C. S.).—Give the hedge copious supplies of water in dry weather, mulch the surface with a couple of inches of littery dung, such as is employed for making Mushroom-beds, and water freely if dry weather continue, so that the nutritive constituents of the manure may be carried down to the roots. In April dig in the manure, and place some fresh mulching on both sides of the hedge to a distance of 18 inches. In May cut it down to 18 inches high, and trim the sides proportionately. It should push freely by July, and make a nice green hedge by autumn; if not, root it up and replant in April, taking care to place some nice rich compost around the plants to give them a start. We transplanted some large Variegated Hollies, some of them nearly 20 feet high, last April, and left the tops on until June, when we cut in the heads, the trees at the time shedding their leaves; now we are to be rewarded by some bushes of pyramidal form with fresh foliage, for the shoots are clustering on the old naked stems, and are already upwards of 6 inches long.

EXTRA CROWNS ON PINE APPLES (Rara avis).—There is nothing uncommon in the facts you state. It is one of the drawbacks as respects the Envire, and is often produced by water lodging in the heart of the plant when the fruit begins to show. Some gardeners remove carefully the most of the crowns, others just let them alone. In general the fruit looks best when there is only one crown, and that one of moderate size.

SEEDLING PELEGRONIUM (Cambrian).—It had shed its petals, but judging of its merits from a bud opened in water, we should say it would prove a useful decorative plant; the colour is bright and lively, with average truss. But it is desirable that a plant should be seen before any decision can be made as to its merits.

BOXES FOR EXHIBITING FLOWERS (Zimri).—We have not seen boxes placed according to your description. Stands are made in which flowers can be placed and then run in like drawers into a case, but the case forms no part of the exhibition-box.

SEEDLING PANSIES (L. F. F.).—They are good border flowers, but only one is sufficiently distinct from others already in cultivation to merit distinction. That one is one of the three "Fancies." It has two plum-coloured upper petals, and the other petals purple.

GREENHOUSE TO SUPPLY A CONSERVATORY (S. B.).—See the Manual on "Heating, &c." You give us too few data to enable us to advise you as we would wish to do. We are in doubt whether the contemplated 14-feet-wide house, and 40 feet in length, is to be a lean-to or a span-roof. If the latter, all the sashes might be fixed, and the ventilators be placed in the side walls, and at the apex of the roof. With a span-roof, side walls of from $\frac{3}{4}$ to 4 feet in height, and the height of the apex from 7 to 8 feet, would give a very serviceable house, and you could have a sparred platform on each side, or an earth bed, covered with rough cinders, for setting the plants on. The latter would be the most economical. The first plan would enable you to keep many things at rest on the ground beneath your platform. For a lean-to of that width, the back wall would require to be from 8 to 9 feet, and the front wall from 3 to 4 feet. The side or hipped-roof would be the best. Then as to having this 40 feet in two divisions, and the one to be much hotter than the other, this would be best done with hot water. You might then also have bottom heat for your beds in one department. The simplest plan of heating such a house, if you can sink your stove-hole low enough, would be by means of a flue beneath the pathway thus—make the end next the stove-hole the warmest end; make a flue and return beneath the pathway, so that you can heat that part separate by itself; continue the flue in the other house, but shut out by means of dampers, the regulating of which will enable you to heat or not heat at will, and less or more, as you think fit, the other 20 feet. This will make your flue altogether 80 feet long before it enters the chimney. A better plan, perhaps, would be to have a chimney at the furnace for the first house, or rather division of 20 feet, and then merely a single flue for the second, and a second chimney at the other end. With a damper to shut off the connection there will be no difficulty. If in the forty-feet length the main flue rises 6 inches or more, the draught will be good. Your proposed plan of roofing the viney will give you more room inside than a mere sloping lean-to roof. Would it not be a good thing to decide at once on the houses you meant to have, and then have one boiler to heat them all? A flue or a stove we consider the most economical as respects small detached houses, but hot water will be best when several houses are to be heated, as there will be waste from only one chimney.

CURRENTS (W. Newman, Harlington).—Your Red Currants are certainly very fine; they are the Red Grape.

SOWING FEVERFEW (Inquirer).—You may sow the seeds of Feverfew any time from now to the beginning of September; but if you wish certainty of results, it will be much better to propagate a favourite kind by cuttings in September.

GLASS FOR ORCHARD-HOUSE (Subscriber, J. G.).—For 21 oz. glass we would decidedly have only 17 inches between rafter and rafter. The squares would thus be 17 inches by 12 or 13, we would prefer 12 inches. This gives more strength to the glass than if the squares were longer than 12 inches, as each lap gives additional strength. We should like the rafters to be $\frac{1}{2}$ inches deep, by $\frac{1}{2}$ inch across. 4 inches deep would do if the roof was a steep span, but if at all flat, $\frac{1}{2}$ inches will be needed. Your proposed glass will answer admirably. You will have abundance of light with glass of 17 or even 16 inches across, and will need a fair amount of air-openings.

STOVE FOR A GREENHOUSE (Miss K.).—If you would tell us how much glass there is on the garden-house, we should be more able to advise. At present we have no doubt that a moveable iron stove would be best, as, probably it would not be needed at all from May to the end of October. A stove, round or square, from 24 to 30 inches in height, and 15 inches square or in diameter, with a flat top, would answer admirably. On the top an iron vessel may be placed for holding water, and supplied with a lid so that you need not have too much moisture in winter. We should like it as wide as we say—as the next best substitute for double sides—as the fire-place of 9 inches square could be thus 3 inches from the outside. The great evil of a smaller stove would be that the sides at the fire would get too hot, and burn the air.

GRAPE BLOTTCHED (T. L. E.).—Without seeing the blotched berries, we can only come to the conclusion that they have been burned or scalded, very likely from the extreme heat, and air not given early enough. If nothing of the kind happened before, we should think this may be the cause. If it happened before, then most likely there are rough spots on the glass that concentrate the sun's rays like a burning glass, and these you must dab with a little paint. You have done right during the glass, but do not overdo it. The berries thus touched will not do much good, but those untouched will be all right, if these measures, and plenty of air given early, are attended to. Very likely, however, the berries may suffer from some other cause, we suspect the disease called "the spot."

NAMES OF INSECTS (V. G. C.).—The Ivy shoots are infested with a species of aphid which is of rare occurrence on that plant. The shoots should be well syringed with Gishurst compound.—W.

NAMES OF PLANTS (W. L., Reading).—There was no No. 1 in your letter; No. 2 is *Lyonia paniculata*, DC. (*Hortus*).—1, *Circsea alpina*, L.; 2, *Claytonia alsinoidea*, Sims. (*C. R.*, *Leeds*).—*Solanum dulcamara* or Bittersweet. (*A. Subscriber*).—The Fern numbered 1.111 is *Lastrea Filix-mas*, *cristata*, originally found in Cornwall.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

JUDGES AT THE APPROACHING ISLINGTON POULTRY SHOW.

AFTER some hesitation I have resolved to reply to your correspondent "AN EXHIBITOR." I am, however, somewhat at a loss to understand his object. As to the first portion of his letter, had he been a member of the Poultry Club he would have found many of his queries unnecessary, as Mr.

Tudman, the Honorary Secretary, submitted the proposed Judges to the Stewards for approval.

If this exhibitor knew anything about the correspondence concerning Mr. Hewitt being a Judge for the Poultry Club he would clearly see that that gentleman has not been appointed. Mr. Tudman is not aware of any quarrel having taken place; and how your correspondent can state that the rules of the Club have been sacrificed or broken down I cannot conceive, for as yet they have been little acted upon, the test being to come.

With regard to making known the names of Judges, there are, I think, very grave objections against doing so, if only affording dishonest exhibitors the means of communicating with them. The three Judges selected by the Club are certainly not exhibitors now. The Islington Show, as your correspondent may see, is under the control and management of the Poultry Club, and why should the Club give up the selection of Judges to the Manager (as suggested) when they can find men, who are members of the Club, so highly qualified to fill the office? To do this would certainly be admitting incapacity and weakness, which, as yet, they assuredly do not. From what has come under my knowledge I feel confident your correspondent is expressing the opinion of himself only, and not of exhibitors generally, which, I believe, the forthcoming Show will demonstrate.

Allow me finally to state that the worthy Honorary Secretaries of the Poultry Club are gentlemen acting and giving their services for the benefit of the poultry-loving community, and these are purely honorary. I therefore beg to state that those for whom they act so disinterestedly must bear in mind the object they have in view; and, although placing themselves open to correction, they are not, at the same time, public property, nor paid servants, who can at any time be reprimanded or dismissed for not carrying out the views and ideas of every little exhibitor who chooses to attack them.—A POULTRY FANCIER.

NEWCASTLE-ON-TYNE POULTRY EXHIBITION.

We were informed on the spot, that not since the years 1858 or 1859 has there been a show of poultry held at Newcastle-on-Tyne. A few amateurs, however, considering that the holding of the Royal Agricultural Society's Meeting at Newcastle would afford an excellent opportunity for reviving this meeting, determined on the attempt, and it gives us great pleasure to state that a very excellent show of both Poultry and Pigeons resulted. The visitors to the Royal Agricultural Show had, in their progress to the Show-yard, to actually pass the Newcastle Hay Market, in which a very spacious tent was erected for the Poultry Show, and the consequence was that these holiday-seekers attended in numbers that few could credit, save those who witnessed it. The fact is, so numerously attended a meeting is the exception rather than the rule of such exhibitions, and we can therefore heartily congratulate the promoters of this Show on the issue.

As to the general appointments, it is simply just to say that everything that could possibly be done was done for the comfort of the valuable stock placed under the care of the Newcastle Committee. The weather was decidedly the hottest of this year, and fresh cut lettuces were placed daily in each pen, a comfort that was evidently most highly appreciated by the specimens exhibited. The tent provided was indeed an excellent one, and spacious enough to satisfy the most anxious owners. The weather, however, was so sultry, that the suggestion was strongly forced on the minds of most parties present that such tents require a more perfect ventilation than is at present provided. Experience proves that it is not from beneath that a fresh current of air is required, but that an outlet should be provided for the heated atmosphere arising from so great a number of visitors, themselves in a state of excessive perspiration in almost every instance, even before entering, and consequently feeling but little relief, even though the canvass of the tent might afford a certain amount of shade from the burning sunshine out of doors. We cannot but believe this difficulty might be easily remedied by the manufacturers of such "pavilions," if at the ridge-pole certain apertures of sufficient size were introduced,

capable of letting away the impure air as it arises from below. We give the suggestion hoping it may receive the consideration of tent-makers generally, as their practical experience will quickly apply some remedy, by which sudden rain might be as effectually provided against as ever, though proper ventilation might yet be quite unimpeded.

In Spanish, Mr. Teebay, of Preston, stood first, with a most capital pen, but, as we anticipated, not so good in condition (from moulting) as we could have wished for. Mr. Rodbard's second-prize pen contained the best pair of Spanish hens in the Show, but the cock was not their equal. The class was good. In Dorkings, excepting the prize birds the competition was not so good as we hoped for, though the winners were capital. The absence of Viscountess Holmesdale's birds (though entered) was a matter of regret to every one, as these north-countrymen pithily observed, "We have heard so much of her ladyship's birds, and that renders our disappointment only the greater." The Cochins were first-rate; Messrs. Bishop, Bates, Shorthose, and others, vieing with our greatest meetings as to their respective merits in the pens competing. Those who did not happen to be present here missed a great treat. The Brahma, too, were capital throughout, large entries. In this variety, Mr. Boyle, of Poyer Park, Dundrum, Ireland, left all competition far in the rear with three pens of Brahma, that, it will be seen by the prize list, left no premium to his rivals. In Hamburghs, the Spangled ones were the best classes of both colours, nor do we expect better. The Polands were also very good. The pen exhibited at Thorne a few weeks back, and there disqualified, of Black Polands, here again put in an appearance; but as, here at Newcastle, the legs were shown naturally, and the tail of the cock only bore the inevitable remnants of the dye from the Thorne Meeting, they were now only passed by without any publicly assigned reason. The Game classes were weak in numbers, and, excepting the prize birds, were not equal to general expectations.

The customary classes for Ducks, Geese, Turkeys, and Bantams, were amply filled with first-rate specimens. We noticed a very nice pen of Sheldrakes, that seemed quite to be public favourites.

The show of Pigeons embraced the best specimens of our first-class breeders, and resulted in a very numerous entry, scarcely was there an empty pen throughout this section of the Exhibition.

SPANISH.—First, R. Teebay, Preston. Second, J. R. Rodbard, Bristol. Third, W. Bruce, Perth. Commended, E. Craddace, Newcastle; J. Redpath, jun., Edinburgh.

DORKINGS.—First and Second, Mrs. F. Blair, Perthshire. Third, Sir G. Gore, Bart., Hopton Hall. Highly Commended, W. Gamon, Thornton-le-Moor; M. Hunter, Green Hammerton Hall. Commended, H. M. Bishop, Nottingham; J. K. Fowler, Aylesbury.

COCHIN-CHINA (Cinnamon or Buff).—First and Second, C. T. Bishop, Lenton. Third, Mrs. F. Blair, Perthshire. Highly Commended, A. A. Smith, Landport. Commended, J. Stephens, Walsall; E. Yardley, Sheffield.

COCHIN-CHINA (Partridge or Grouse).—First, H. Bates, Birmingham, Second, J. R. Rodbard, Bristol. Third, T. Stretch, Ormskirk. Commended, E. Smith, Middleton.

COCHIN-CHINA (White).—First, Mrs. F. Blair, Perthshire. Second, W. Dawson, Hopton Mirfield. Third, D. Causer, Erdington.

BRAHMA POOTRA.—First, Second, and Third, R. W. Boyle, Poyer Park, Dublin. Highly Commended, Mrs. F. Blair, Perthshire.

GAME (Black-breasted and other Reds).—First, Sir G. Gore, Bart., Hopton Hall. Second, H. Adams, Beverley. Third, G. W. Binns, Darlington. Highly Commended, Sir G. Gore, Bart.

GAME (Any variety).—First, J. B. Chune, Coalbrookdale. Second, H. Adams, Beverley. Third, Sir G. Gore, Hopton Hall.

HAMBURGH (Golden-pencilled).—First, C. Pease, Darlington. Second, T. Smith, Northowram. Third, T. Birch, Sheffield. Commended, H. Beldon, Gilstead, Yorkshire.

HAMBURG (Silver-pencilled).—First, E. Yardley, Sheffield. Second, H. Beldon, Gilstead. Third, J. Leary, Rothbury.

HAMBURGH (Golden-spangled).—First, W. Cooper, Helmsley. Second, T. Birch, Sheffield. Third, H. Beldon, Gilstead. Commended, R. Harrett, Kirkwhelpington; Sir G. Gore, Bart., Hopton Hall; S. H. Hyde, Taunton Hall.

HAMBURGE (Silver-spangled).—First, H. Beldon, Gilstead. Second, Sir G. Gore, Bart., Hopton Hall. Third, C. Pease, Darlington. Highly Commended, J. Robinson, Vale House, Garstang.

POLAND (Gold or Silver-spangled).—First and Third, H. Beldon, Gilstead. Second, C. Pease, Darlington.

POLAND (Any other variety).—First and Second, H. Beldon, Gilstead. Third, Mrs. F. Blair, Perthshire.

ANY VARIETY (not named above).—First, Mrs. F. Blair (La Flèche). Second and Third, C. Pease (Silks and Black Hamburgs). Commended, H. Beldon.

CHICKENS.

SPANISH.—First, J. R. Rodbard, Bristol. Second, E. Brown, Sheffield. Third, W. Massey, Gedney.

DORKING (Coloured).—First, Mrs. F. Blair, Perthshire. Second, Rev. J. G. A. Baker, Biggleswade, Beds. Third, H. Beldon, Bingley. Highly Commended, R. W. Boyle, Poyer Park, Dublin; J. White, Warlaby, Yorkshire; Mrs.

Seamons, Hartwell, Bucks; Rev. J. F. Newton, Kirby-in-Cleveland. Com-mended. J. Robinson, Vale House, Garstang.

COCHIN-CHINA (Cinnamon or Buff).—First and Third, J. Shorthose, New-castle. Second, T. Stretch, Ormskirk. Highly Commended, T. H. Baker, Hovingham; J. Shorthose.

COCHIN-CHINA (Partridge or Grouse).—First, S. Robson, Brotherton. Second, T. Stretch, Ormskirk. Third, P. Cartwright, Oswestry.

GAME (Any colour).—First, W. T. Everard, Bardon Hill House, Leicester. Second, H. Thompson, Old Hutton, Westmoreland. Third, A. E. Dyas, Madeley. Highly Commended, T. Cleminson, Darlington.

ANY VARIETY (not named above).—First, H. Beldon, Gilstead. Second, H. S. Stobart, Witton (White Cochins). Third, G. Brooks, Huddersfield (Golden-spangled Hamburgs). Commended, Mrs. Seamons, Hartwell, Bucks (Brahma Poutra); J. Wright, Woodbridge.

DUCKS (Aylesbury).—First and Second, Mrs. Seamons, Hartwell, Bucks. Highly Commended, O. A. Young, Driffield. Commended, J. Robinson, Vale House, Garstang.

DUCKS (Rouen).—First, J. K. Fowler, Aylesbury. Second, Mrs. F. Blair, Perthshire. Highly Commended, J. Robinson, Vale House, Garstang.

DUCKS (Any variety).—First, C. Pease, Darlington. Second, J. R. Jessop, Hull. Highly Commended, J. G. Milner, Leyburn.

GESE (Any colour).—First, Mrs. Seamons, Hartwell, Bucks. Second, Mrs. F. Blair, Perthshire. Highly Commended, Mrs. F. Blair. Commended, J. K. Fowler, Aylesbury.

TURKEY COCKS.—Prize, Mrs. F. Blair, Perthshire. Second, C. Pease, Darlington. Highly Commended, J. Wilson, Woodhorn; J. K. Fowler.

TURKEY COCKS.—Prize, Mrs. F. Blair, Perthshire. Second, C. Pease, Darlington. Highly Commended, J. Wilson, Woodhorn; J. K. Fowler.

BANTAMS (Game).—First, C. W. Wilson, High Park, Kendal (Pile Game). Second, R. M. Stark, Hull. Highly Commended, G. Malpas, jun., Liver-pool. Commended, H. Bates, Birmingham; J. Crossland, Wakefield.

BANTAMS (Gold or Silver-laced).—First, H. Beldon, Second, F. L. Roy, Neathorn. Commended, R. Adams, Birmingham; R. Stark, Hull.

BANTAMS (Any variety).—First, H. Beldon, Gilstead, Yorkshire. Second withheld.

SINGLE COCKS.

GAME.—First, Sir G. Gore, Bart., Hopton Hall. Second, H. M. Julian, Hull. Third, Sir G. Gore, Bart. Highly Commended, J. B. Chune, Coal-brookdale.

BANTAMS (Game).—First, G. Malpas, jun. Second, R. M. Stark. Third, R. Swift, Southwell.

SPANISH.—First, H. Beldon, Gilstead, Yorkshire. Second, W. Massey, Gedney, Lincoln.

DORSETTS.—First, Rev. J. F. Newton, Kirby-in-Cleveland. Second, Rev. J. G. A. Baker, Biggleswade, Beds. Commended, Mrs. F. Blair, Perthshire.

COCHIN-CHINA (Cinnamon or Buff).—First, Mrs. White, Broomhall Park. Second, R. Adams, Birmingham. Highly Commended, C. T. Bishop, Lenton; F. Dickens; T. H. Barker. Commended, C. Kershaw, Ashton-under-Lyne.

COCHIN-CHINA (Partridge or Grouse).—First, R. Adams. Second, R. White.

BRAHMA-POOTRA.—First, H. Lacy, Hebden Bridge. Second, Captain Potter, North Shields. Commended, J. Wright, Woodbridge.

POULTRY SELLING CLASS (Any breed).—First, E. Brown. Second, G. W. Binns, Darlington. Third, G. Brooks, Huddersfield. Highly Commended, J. White; W. Massey (Bantams). Commended, G. Crudace (Cochins); F. L. Roy.

PIGEONS.

CARRIER (Any colour).—**Cock**.—First, F. Else, Bayswater. Second, W. B. Van Haansbergen. Commended, H. Yardley, Birmingham. **Hen**.—First, F. Else. Second, H. Beldon, Gilstead, Yorkshire. Commended, W. B. Van Haansbergen, Benwell.

POWTERS (Any colour).—**Cock**.—First, W. Ashworth, Owlerton. Second, W. Massey, Gedney. **Hen**.—First and Second, G. R. Potts, Sunderland. Commended, M. E. Jobling, Barras Bridge.

BARES (Any colour).—**Cock**.—First, W. B. Van Haansbergen. Second, H. Beldon. **Hen**.—First and Second, W. B. Van Haansbergen.

TUMBLERS (Short-faced).—First, G. R. Potts, Sunderland. Second, H. Beldon. Commended, H. Yardley, Birmingham.

TUMBLERS (Common).—First and Second, M. B. Jobling, Barras Bridge.

TRUMPETERS (Any colour).—First, H. Beldon. Second, W. B. Van Haansbergen.

FANTAILS (Any colour).—First, F. Else. Second, H. Yardley. Highly Commended, M. E. Jobling. Commended, H. Yardley.

JACOBIANS (Any colour).—First, M. E. Jobling. Second, W. Veitch, jun., Jedburgh.

OWLS (Any colour).—First and Second, G. Byers, Seaton Sluice. Highly Commended, M. E. Jobling.

TURBITS (Any colour).—First and Second, M. E. Jobling. Highly Commended, F. Key, Beverley; T. C. Taylor, Middlesborough.

NUNS (Any colour).—First, W. Johnson, Carlisle. Second, F. Key, Beverley.

MAGPIES (Any colour).—First, M. E. Jobling. Second, F. Else. Highly Commended, M. E. Jobling.

ANY VARIETY NOT NAMED BEFORE.—First, M. Smushall, Gedney. Second, M. E. Jobling. Highly Commended, M. E. Jobling.

PIGEON SELLING CLASS (Any variety).—First, J. B. Chune, Coalbrook-dale (Jacobins). Second, H. Smushall, Gedney. Third, M. E. Jobling (Magpies).

EXTRA PRIZES—A Silver Medal, presented by M. E. Jobling, Esq., for the best pair of Bars—W. B. Van Haansbergen. A Silver Medal, presented by J. Van Haansbergen, Esq., for the best pair of Blue Owls.—M. E. Jobling. A Silver Cup, given by Lord Decies, to the most successful exhibitor in the poultry classes.—H. Beldon, Gilstead, Yorkshire. Silver Cup for the best pen of Chickens.—J. R. Rodbard, Bristol. Gold Medal, given to the most successful exhibitor in the Pigeon class.—M. E. Jobling.

Edward Hewitt, Esq., of Sparkbrook, Birmingham, officiated for the Poultry; and T. W. Botcherley, Esq., of Darlington, awarded the prizes in the Pigeon classes.

RULES FOR JUDGING POULTRY.

I HAVE never seen the rules of the Poultry Club, and do not belong to it. In fact, a reply which I received to an application I some time since made to the Secretary on the subject, led me to believe that no new members were desired. I am, consequently, not an advocate of their rules, and, indeed, know nothing about them. I say this much, so that I may not be thought an interested party in this discussion.

It would, I admit, be absurd to make rules as to non-essentials; but do I correctly infer that you are, therefore, of opinion that it would be absurd to have rules as to essentials? If I do, I must say with all deference to you, Messrs. Editors, that I cannot see the common sense or logic of your conclusion. At present it is manifest that there is considerable difference of opinion amongst judges as to what is and what is not essential, and hence the conflicting decisions as to the merits of pens of poultry shown at different shows, and judged by different persons.

We all know, for it is notorious, that a pen placed first at one show will often, without any apparent reason other than difference of opinion in the judges, have to give way to a pen which it had before beaten, and, perchance, be unnoticed altogether.

Bearing this fact in mind, I cannot help believing that amateurs would gladly have some standard rules which should guide them in breeding their fowls, and the judges when judging them. Of course, a great deal must always depend on the judges; for instance, where there is uneven matching in size, &c., or where some pens are shown in better condition than others; but I am quite unable to understand how any judge's labours as to these points can be enhanced by certain and intelligible rules on essential points being reduced to writing. If such were generally acted on by them and by breeders, I cannot divest myself of the notion that not only would exhibitors generally be more satisfied with awards, but that really competent judges would find their labours more easy and agreeable than at present.

I hope I shall not be understood as insisting that rules of any kind will, or can, make every man a good and efficient judge; I believe nothing of the kind. To be a thorough judge requires peculiar and rare qualities, besides considerable experience, and lacking these no man with the most minute directions would ever make a judge whose decisions would give the poultry-loving public satisfaction.—P.

[It seems to us that there is no difference of opinion between our correspondent and ourselves. The essential characteristics of the varieties are well known, and we never knew a judge of poultry disregard them. If it be thought desirable to have them printed there can be no objection. When a pen takes a prize at one show, and is not noticed at another, it only intimates that their competitors in the opinion of the judge had a preponderating amount of non-essential excellencies.]

BEES IN PERTHSHIRE.

I HAPPEN to reside in the centre of Perthshire on the banks of the "majestic Tay," in one of the most picturesque spots in the country. I am surrounded on all sides by hills covered with extensive forests, or clad with the purple heather. The hazel, the willow, the alder, the beech, the plane, the oak, the mountain ash, the hawthorn, and the holly, in point of blossom, I have in no former season seen surpassed. These trees afford rich pasture for bees. The broom, the furze, and the blackberry are also abundant. There is in general a deficiency of white clover in this district, the soil or the climate not being suitable to its continued existence. It flourishes for a year or two and then becomes extinct. The white clover affords the richest pasture to the bee, and where the plant is abundant and luxuriant the bees prefer it to any other flower. The lime trees are also numerous here, but they are not yet in flower. The bees are particularly fond of the lime, and when a genial south-west wind blows they collect enormous masses of honey from its myriads of sweet-smelling blossoms. The heath is also abundant, covering with its purple blossoms many a square mile of surface. It does not flower until the beginning of August.

With regard to the character of the weather, in the early part of the season it was very cold and unfavourable. Many

of the country people, however, do not consider such weather unpropitious to bees, especially if it terminate by the middle of April. The latter part of April and the month of May were very favourable, and during these months most of my stock-hives made great progress, and increased much in population. The temperature was so high during the latter part of May that large masses of bees hung in clusters and festoons about the entrances and underneath the stools of the hives, and several hives in the district swarmed. There was one swarm so early as the 15th of May—an unusual occurrence in this locality. The last ten days have been very unpropitious. Many hives that were preparing to swarm were arrested in their progress, the bees destroying the drones in their larva and pupa conditions, and tearing down the royal cells that were in course of construction.

The great obstacle to the prosperity of bees in this quarter is the state of the weather, and so much has this been the case during my experience, which extends to more than a quarter of a century, that I have sometimes thought the climate entirely unsuited to such insects. During the last three or four years the seasons have been especially unpropitious, and as a natural consequence thousands of hives have perished, and many apiaries have gone to ruin.

I have at present four apiaries consisting of nineteen hives, and with the exception of two all in common straw hives. The first apiary is in a back area adjoining my dwelling-house. It consists of two hives—one a foundling, which I had literally dug out of the roof of a house to which it had migrated last season, and which I had transferred to a Huber-hive, and the other the swarm that had taken possession of the glass hive in my attic window, and to which I alluded in a former communication. These two hives are rapidly progressing in strength, but they are "far behind" for the season. The population of the foundling may average 10,000, and that of the glass hive 5000 or 6000. No drones have yet (June 10th) appeared. This apiary is so surrounded with tall lime trees, and high gables of houses, that the bees have often difficulty in surmounting them, having to mount up a spiral of 40 or 50 feet in height. Any natural swarm coming off in this apiary is generally lost.

In the second apiary I have only one hive. It is in good condition, and may swarm in about a week. My third apiary is situated in a distant forest, in the midst of a young oak coppice; the disadvantage of this apiary lies in its distance from immediate observation. The bees, however, are most vigorous, healthy, and prosperous. Their peculiar hum as they depart from and return to their hives is very pleasing. This apiary consists of four hives, three young hives and one old hive. The old hive is unusually strong in bees, and at present is lying out in masses on the stool. Drones have appeared in all the hives, and they are in good condition. No swarms have yet been sent forth. Though, perhaps, it would be for my interest to make artificial swarms, I have such a desire to witness the egress of natural swarms that I have as yet delayed forming any. One of the four is an artificial swarm of last year, which had only half filled its hive with comb; but by this time it must have brought it down to the surface.

The fourth apiary consists of twelve stocks domiciled in straw hives; eight of these are young swarms of last year, and four old stock-hives. Nine are in first-rate condition, lying out in masses, and abounding in drones. The cause of the bees in so many hives clustering in such masses on the board lies in the circumstance of their having been arrested by the cold weather in the process of constructing royal cells, and having no royal cells sealed the old queen is unwilling to emigrate.

In closing this article can any aparian inform me whether he has ever known a swarm emigrate without a royal cell sealed, or in process of being sealed, in the old stock?—*PHILISCUS, Dunkeld.*

WORRIED TO DEATH.

ON the 14th inst. I missed the young queen of a small artificial swarm. After a long and unavailing scrutiny of every comb, I at length bethought me of examining the ground in front of the hive, and there I found the body of the unfortunate queen. Its peculiar appearance at once satisfied me that she had been pinioned and literally worried

to death by her own workers; and although I failed in detecting the usual sign of impregnation, I more than suspected that the maltreatment to which she had fallen a victim had closely followed her return from a successful wedding trip. Three days afterwards I found these suspicions verified in the case of a very beautiful young queen of another small artificial swarm, whose lifeless body I extricated from a dense cluster of workers within the hive, the sign of impregnation in this case remaining distinctly visible.

Can any one suggest a reason for these singular aberrations in the instincts of bees, dooming the community in each instance to certain extinction by the destruction of its juvenile sovereign at the very moment when she had become fully capable of fulfilling her important functions?—A DEVON-SHIRE BEE-KEEPER.

NATURAL AND ARTIFICIAL SWARMS.

PERHAPS the result of my driving operations condemned in your Journal of the 28th ult., may not prove uninteresting. On July 1st, and the three following nights, piping was heard in the old stock. On July 5th a fair-sized swarm issued, and settled so quickly in a neighbour's orchard that had I been absent for fifteen minutes it might have been lost to me. Might I have driven again, or could I have done anything to prevent the swarming? In the afternoon the old stock expelled dead two young queens. I have, therefore, had from one stock, first, a natural swarm, which sent out a maiden swarm (a very large one) on July 10th; next, two artificial swarms (both doing well); lastly, a natural swarm.—A VILLAGE DOCTOR.

[You certainly ran great risk in your operations, but good luck has pulled you through. Young queens do not on the average lay eggs until they are fourteen days old, but the one you saw on the 25th of May, must have left brood behind, although but twelve days old at the time she quitted the old stock. You could not have prevented the swarm which issued on the 5th of July.]

BEES IN SUPERS.

OVER one of my hives, a common straw one with flat board at the top, in which there is a circular hole, I have placed a bell-glass. The bees congregate there in numbers, but show no signs of building or forming the comb. Ought I to have attached a small piece at the top (inside) as an inducement? or will they do it of their own accord when the hive is filled. I am quite a beginner in the aparian line, having bought two stocks only last autumn. One died during the winter; the other threw out two swarms in May and June, which I put into these new hives, made in the village, and have now placed the bell-glasses over. I placed the bell-glasses over because the bees hung out so much, and I was afraid they would swarm, which (the people say here), in July is not worth a butterfly. They only look at and visit the extension of their new homes, but will not build. I ought to say the glasses are rather large—9 or 10 inches in diameter. Is the extent of their new apartments too large, or what is the reason? I have placed an empty hive over the glasses, so that they are in darkness.

Supposing they do form the combs and fill the glasses with honey, how am I to take the glasses off so as to get the contents without injuring the bees, and when is the proper time for doing so?—RECTOR, Kent.

[If the bees remain in the bell-glasses they will probably form combs therein, but would have done so more readily if some clean comb had been fixed in them beforehand. The glasses should be taken off when filled, or when the honey season is over. Full directions for removing supers are given in page 125 of the sixth edition of Taylor's "Bee-keeper's Manual."]

OUR LETTER BOX.

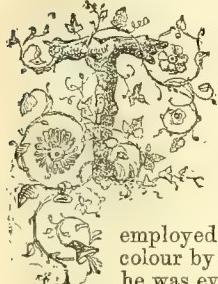

APIARIAN REQUISITES—SUPERING STOCKS (*Château Vallon*).—Mesars. Neighbour & Son supply bell-glasses and caps, and in their advertisement, which appears in another column, you will find a list of agents, but none we fear in Yorkshire. Can any of our readers say where aparian requisites are sold in that county? Caps or supers may be used with advantage as long as the honey harvest continues, and if there be much heath near you, may even now be of service.

WEEKLY CALENDAR.

Day of M'nth	Day of Week.	AUGUST 2-8, 1864.	Average Temperature near London.			Rain in last 37 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.
2	TU	Mugwort flowers.	Day.	Night	Mean.	Days.	m.	h.	m.	h.	m.	s.	
3	W	Common Bent Grass ripe.	75.9	52.1	64.0	18	27	af 4	45	af 7	32	4	215
4	TH	Honeysuckle berries ripe.	74.7	51.1	62.9	19	29	4	43	7	36	5	216
5	F	Yellow Succory flowers.	75.6	51.2	63.4	16	30	4	41	7	38	6	217
6	S	PRINCE ALFRED BORN, 1844.	73.9	51.2	62.6	17	32	4	40	7	41	7	218
7	SUN	11 SUNDAY AFTER TRINITY.	72.7	50.9	61.8	17	33	4	38	7	46	8	219
8	M	Saintfoin flowers.	74.7	50.5	62.6	13	35	4	36	7	50	9	220
			74.3	49.7	62.0	16	36	4	34	7	54	10	221

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 74.5°, and its night temperature 50.9°. The greatest heat was 92° on the 2nd, 1856; and the lowest cold, 37°, on the 6th, 7th, and 8th, 1851. The greatest fall of rain was 1.03 inch.

HARDY BEDDING PLANTS.

HERE ought to be gardens for all the months of the year, in which, severally, things of beauty may be had in season." This is Lord Bacon's ideal of a perfect garden in the seventeenth century. At this time embroidered gardens had been introduced from France, and though not adverse to art being employed to produce harmony of form and colour by the panel-work and its embroidery, he was evidently of opinion that this form of garden was not what a lover of Nature could be satisfied with.

In the present day, embroidered gardens, and polychrome or parti-coloured figures have been introduced, and I have seen them at many places, the flowers in summer being skilfully arranged in geometrical beds, ribands, compartments, or scrolls, separated from each other by narrow paths or alleys formed of permanent-coloured materials instead of gravel only, and the whole resembling a many-coloured carpet, in which the plants are trimmed or otherwise made to assume an appearance little differing from that presented by the dead colouring materials. I have also seen these gardens in winter, and found the coloured materials, which are the winter substitutes of flowers, not giving the effect produced by the glowing tints of life. In fact, in spring, autumn, and winter, these fancy gardens with their parti-coloured arrangements, and lively combinations of small toy-like shrubs do not give that appearance in winter which we were led to expect.

My impression of embroidered parterres is, that they cannot be pleasing to the real lover of Nature and art, for true art does not see anything more beautiful than Nature. The beauty of a picture consists in its near approach to nature, and the beauty of a garden, no matter how trim and well kept it may be, rests on each occupant presenting a natural appearance. When art is duly applied to Nature's works, their wildness and irregularity only are rectified.

My notion of a garden, no matter how limited or extensive the area may be, is, that it should be ornamental at all seasons. To make it so, fair selections should be made—1st, of evergreen, flowering, and deciduous trees and shrubs; 2nd, of plants flowering or otherwise attaining their greatest beauty at different periods of the year; 3rd, and the whole should be arranged so as to form a beautiful picture in spring, summer, autumn, and winter. We should not then see every inch of available surface occupied by plants yielding a mere monotonous blaze of colour for three months out of the twelve.

Having made these preliminary remarks, I may now state my impressions as to the present system of arranging plants in beds, in order that I may be the better understood. 1st. I think the system of massing plants the most natural of all, for in nature plants are distributed

in groups, yellow here, red there, white or blue elsewhere. 2nd. That for producing an effect, and making the most of some plants that appear diminutive when placed singly, that system is unequalled. 3rd. That masses judiciously introduced without taking up the ground required for other plants, give a feature to a garden not otherwise to be obtained. 4th. That when all the contrivances, and most of the labour and means of a place are devoted to bedding plants, and when every nook and corner is filled with them, to the exclusion of other plants equally beautiful, though not tender, for the sake of a short brilliant display of bloom in summer, then is this system misapplied.

Now, for affording a fine display of bloom in summer, no plants are more suitable than those having a decided colouring, either of bloom or foliage, there being but one colour, pure, distinct, and bright; the habit must be dwarf and compact; the flowers of good substance, borne well above the foliage, but not so as to present an uneven surface; and the blooming must be profuse, and of three months' continuance. The plants, moreover, should be of good constitution, and capable of enduring wind, rain, and other peculiarities of the climate. These being the conditions of a good bedding plant, it is evident that those plants doing well in our climate without the aid of artificial protection in winter, are the most likely to withstand the changes of our climate; those requiring artificial protection in winter, or nearly at all seasons, being only employed as auxiliaries furnishing something in colour, form, or foliage not found in hardy plants. The day may be distant, but I believe it will come, when the horticulturist will be able to fill his beds with plants needing no more protection in winter than that of a cold frame, and be able to obtain an effect equal to that furnished by hardy and tender plants combined. This is a desideratum for which the hybridiser is striving, and the gardener longing; and employers will then have handsome winter-flowering plants at a dreary time of the year, in place of thousands of Geraniums, &c., that contribute nothing to the ornamentation of the structures, but entail a great amount of labour and expense.

Though the time has not yet arrived when we can substitute hardy plants for tender without destroying the splendour of the flower garden, I am persuaded that many hardy plants might now be employed, especially in places where the amount of glass is small, and that glass desirable for furnishing plants blooming in autumn, winter, and spring. We have so many fine hardy bedding plants, that I shall begin with them, though I ought to have taken shrubs first; and I am the more induced to do so from a clergyman having given me an account of the fine display of flowers which he keeps up without wintering a single bedding plant except Geraniums, as he employs hardy plants instead.

The merits of hardy plants are—they need little or no artificial protection, consequently the greenhouse is not turned into a repository for fading, drooping plants every autumn; and they require but little care one half the year. In their case no daily attention is needed to picking off dead leaves, watering, and giving air. They withstand

rain, heat, and cold, with the other vicissitudes of our climate, and can be grown by any person having ground, and a taste for gardening.

VARIEGATED HARDY BEDDING PLANTS.

BELLIS PERENNIS AUCUBÆFOLIA.—Perhaps the best of all golden variegated plants. It grows about 3 inches high, has bright scarlet flowers in early summer, and is second to no edging plant known. Division of the root.

FRAGARIA VARIÉGATA (Variegated Strawberry).—Beautiful silver variegation. Grows about 6 inches high. Forms very pretty white panels in borders, and is adapted for growing under trees if the spot is not too dry. Of easy culture, and adapted to all soils. Increased by runners.

IRIS GERMANICA VARIÉGATA.—Height 1 to 1½ foot. White stripes along the sword-like leaves, which give it a fine appearance in a ribbon-border. Division of the root.

SHAMROCK (*Trifolium repens*).*—Black and green leaves. Height 6 to 9 inches. A centre of *Achillea aurea*, a ring of Shamrock round it, and an edging of *Arabis caucasica* variegata, make a superb bed. Seed, division, and cuttings.

MELISSA VULGARIS VARIÉGATA (Golden Variegated Balm).—Deep golden blotch. Height 1 foot. Liable to lose its variegation in rich soils in autumn. Good for small or medium-sized beds. Cuttings and division of the root.

SPIREA ULMARIA VARIÉGATA (Variegated Meadow Sweet).—Very sweet, and beautiful when planted as the back row of a ribbon. Suckers and division.

ARABIS LUCIDA VARIÉGATA.—As a dwarf bedding plant this is surpassed by none, and equalled by few. It is a first-rate plant for tessellated patterns, and margins of beds. Suckers or offsets. It is the *Arabis alpina* variegata of some gardens.

ARABIS ALBIDA VARIÉGATA.—More free in habit than the preceding, and having white variegations. It is sometimes called *Arabis caucasica* variegata and *A. grandiflora* variegata. It is a charming edging plant to go next grass, and for filling-in angles, &c., in tessellated patterns. Division of the roots or cuttings.

ALYSIUM SAXATILE VARIÉGATUM.—Much used in embroidered parterre patterns. It forms a lovely yellow bed in spring, and the foliage tells afterwards, but at best it is not equal to many other variegated plants. Cuttings and division.

ALYSIUM DENTATUM VARIÉGATUM.—Of free branching habit, with lanceolate leaves uniformly belted with creamy yellow. By pinching out the fore shoots it forms a dense short growth; suitable for an edging, or a row from 6 to 12 inches wide in a ribbon. Cuttings.

GLECHOMA HEDERACEA VARIÉGATA.—Golden variegation; the plant dwarf, free-growing, and forming a good edging. A lovely plant also for variegated tracing, a charming rockery plant, and a gem for hanging-baskets. Cuttings and division.

AETEMISIA VULGARIS VARIÉGATA.—White variegation. Useful for large patterns requiring a silver ground, or a back row in a ribbon. Division.

BALLOTA NIGRA VARIÉGATA.—Leaves beautifully spotted with white. Forms a neat silvery bed, but requires pegging down. Division.

EUPHLODIA PODAGRÆA.—Fine golden variegation. Suitable for filling up where a light golden mass is desired. Division.

AIRA CERULEA VARIÉGATA.—A very graceful striped-leaved Grass, its beauty being strikingly apparent in the third or fourth row of a ribbon. Division.

DACTYLIS GLomerata VARIÉGATA ELEGANTISSIMA.—A pretty new dwarf Grass, growing about 1 foot high, forming a charming row in a ribbon; and its graceful character will render it valuable for imparting a light appearance to heavy masses of colour and stiff formal outlines. Division.

THYMUS VULGARIS VARIÉGATUS.—A neat plant for forming edgings to beds, and for chain patterns. Division.

MELISSA PATERSONI (Silver Variegated Balm).—Neat and pretty for margins of beds. Cuttings and division.

LONICERA BRACHYPODA VARIÉGATA (Gold-netted Japanese

Honeysuckle).—The leaves of this are permanently netted over with bright golden veins. It forms a fine bed and a neat edging, and is handsome as a climber. Cuttings and layers.

VERONICA CHAMÆDRYS VARIÉGATA.—A fine plant, with the brightest of bright blue flowers and silvery variegated foliage. Indispensable for chain and small patterns. Novel as an edging. Division.

SCROPHULARIA NODOSA VARIÉGATA.—Leaves blotched with white; habit vigorous, but may be had any height by pinching back. Fine for ribbons. Cuttings and division.

SAXIFRAGA JAPONICA VARIÉGATA.—Hardy, with large leaves, creamy white, green, and deep rose. A first-rate plant for edgings or broad belts. Division.

VINCA MAJOR VARIÉGATA.—Silver variegation. Effective, and will grow under trees, and almost anywhere. Cuttings and offsets.

VINCA MINOR VARIÉGATA.—White variegation, and when trained close to the ground forms a carpet-like ornament. Cuttings, layers, and offsets.

FROSTED SILVER AND HOARY-LEAVED HARDY BEDDING PLANTS.

ACHILLEA CLAVENNAE.—Dwarf habit; foliage silver grey; flowers white, borne in dense clusters, which require to be cut off closely, and then we have a plant for a ribbon, row, or belt from 4 to 6 inches high, and retaining its uniform height and compactness throughout the season. Division and cuttings.

DIOTUS MARITIMA.—A low, trailing, pretty plant, with blue-tinted silver grey nap; requires close pegging. Very distinct, and forms a lively contrast where green shades predominate. Cuttings.

NEPETA CÆSIA.—Hoary leaves and violet flowers. Excellent for chains or planting round beds of evergreen shrubs, as Rhododendrons. It makes a good small bed, and is excellent as a belt to yellow beds. Division and cuttings.

CINEARIA MARITIMA.—One of the finest silvery plants we have. A bed of this, or rather a centre, with a broad band of *Saponaria ocymoides* round it, is splendid. Suitable for ribbons, and generally useful for effect anywhere. Seed, division, and cuttings.

ANTENNARIA MARGARITACEA.—Effective silvery foliage. Suitable for belts, chains, and ornamentation generally. Division.

ANTENNARIA ARENARIA.—Effective plant for belts, chains, tessellated patterns, &c. Division. This is an Everlasting.

ARTEMISIA ARGENTEA.—As a neat half-shrubby plant with silvery grey foliage, employed as an edging to large beds or borders of shrubs, clipped to the required height and width, this is unsurpassed. It forms a uniform band or line of any size, and as a clump on a lawn is a fine object. Cuttings and division.

CERASTIUM BIEBERSTEINI.—A better and more silvery species than *C. tomentosum*; stronger in habit and more effective as an edging or ribbon plant. Division and cuttings.

CERASTIUM TOMENTOSUM.—Fine for ribbons, chains, and edgings. Division, seeds, and cuttings.

CERASTIUM GRANDIFLORUM.—Erect tuft-like habit, from 6 to 9 inches high, linear-lanceolate leaves, 1 inch long, of a glaucous silvery hue. Distinct and fine; suitable for ribbons, bands, chains, and ornamental work generally, and will be a general favourite. Division and cuttings.

STACHYS LANATA.—Glaucous woolly leaves, dwarf habit. Unsurpassed for close carpet-work and neutral belts, growing well under trees. Cuttings and offsets.

ORIGANUM PSEUDO-DICTAMNUS.—Round whitish grey leaves, and neat as an edging. Division.

SALVIA OFFICINALIS VARIÉGATA.—Tricoloured leaves. Promises to be an effective plant for edgings and ribbons. Cuttings and division.

GNAPHALIUM LANATUM.—Shrubby and bushy habit, silvery foliage; effective for ribbons, edgings and belts. Cuttings.

CENTAUREA MONTANA.—Very silvery foliage. As yet scarce. Fine for centres of beds, and valuable as a hardy plant. Allied to *C. argentea* and *C. ragusina*. Cuttings and seeds.

ANTENNARIA HYPERBOREA.—Dense and dwarf tufts, leaves silvery on both sides. Likely to be a favourite for edgings, ribbons, and tessellated patterns. Division.

VERONICA CANDIDA.—Dense tufts of intense glaucous

* The true Shamrock is now considered to be *Oxalis acetosella*, Common Wood Sorrel; but the plant known in gardens as Shamrock is *Trifolium repens pentaphyllum*, or Five-leaved White Dutch Clover.

silvery leaves, 6 to 9 inches high. Very effective for ribbons, chains, and beds. Division.

GNAPHALIUM LEONTOPODIIUM.—A very dwarf-tufted plant, the dense heads of flowers appear as if quite smothered in fine silky wool. As an edging plant this is distinct and effective. Division.

ERITRICHUM NANUM.—Dwarf silky tufts, with heads of rather large vivid blue Forget-me-not-like flowers. Division.

HARDY FLOWERING BEDDING PLANTS.

SAPONARIA OCYMOIDES.—As a dwarf plant for beds nothing is more beautiful than this when covered with its myriads of rose-coloured blossoms, whilst for edgings it is one of the most striking and interesting of plants. Division and cuttings.

LYCHNIS (AGROSTEMMA) CORONARIA.—This plant has the soft silvery foliage of *Stachys lanata*, with fine racemose corymbs, 1½ to 2 feet high, of vivid magenta-crimson flowers. It is valuable for ribbons and masses. Seed and cuttings. A crimson variety, I am informed, was much cultivated twenty or thirty years ago; also, a double crimson kind, and a white one, *L. coronaria alba*, but I fear they are lost.

LYCHNIS HAAGEANA SUPERBA.—Brilliant orange scarlet flowers. Plant 1 foot to 18 inches high. Cuttings and divisions.

LINARIA ALPINA.—A prostrate silvery tuft covered with terminal corymbs of purple flowers with fiery orange centres. When strong plants two or three years old are employed, they form dense patches of great beauty. Very effective in masses. Seed.

LYTHRUM ROSEUM SUPERBUM.—Tall, dense, branching spikes of vivid rose-coloured flowers from 2 to 3 feet high, forming an effective back row in a ribbon. Unequalled for producing a heavy mass of colour. Division and cuttings.

SILENE RETICULATA.—Rose-coloured blossoms, having a charming effect in a bed. Division and cuttings.

ANTIRRHINUM.—Numerous varieties. Cuttings and seed.

ENOTHERA MACROCAEPA.—Lovely large yellow flowers, one of the finest bright yellow bedding plants. Seed and cuttings.

ENOTHERA RIPARIA.—A pretty dwarf bright yellow-flowered plant. Cuttings and seeds.

LINUM MONOGYNUM.—Flowers much like *L. grandiflorum*, but white, continuing a long time in bloom. Cuttings.

ACHILLEA AUREA.—Fine golden yellow. Division.

ACHILLEA EGYPTIACA.—Glaucous leaves. Flowers pale yellow. Division.

There is a variety of the Common Yarrow with rosy purple flowers, which grows from 1 foot 6 inches to 2 feet high, and is very effective in beds.

PYRETHRUM PARTHENIUM FLORE PLENO.—A fine pure white bedding plant, suitable for a ribbon next to a scarlet. Does well in dry shady places. Cuttings and division. There are many new varieties of various shades of colour, which I think will be acquisitions.

PANSIES.—Double Purple, or Good Gracious, Trentham Blue, Purple King, White Queen, Yellow Prince. These, in beds of one or more colours, produce a fine effect, and there are few finer beds than a mass of fancy varieties or mixed Pansies. Cuttings, seeds.

FENTSTEMONS.—Charming bedding plants, of dwarf habit, and continuing long in bloom. Their colours vary from bluish purple to rosy carmine and scarlet. Cuttings.

DELPHINIUM FORMOSUM.—This forms a splendid bedding plant. Every other plant should be stopped when the shoots are 6 inches high, in order that the bloom may be of longer continuance. Flowers bright deep blue. Seed and division.

CALCEOLARIAS.—These only require the protection of a cold frame. They vary in colour, being crimson, brown, pale yellow, or orange, and are amongst the handsomest of bedding plants. Cuttings.

MYOSOTIS PALUSTRIS.—Bright blue, with pink eye. Charming as a blue edging plant. Division.

MYOSOTIS ALPICOLA (*M. alpestris*, Hooker).—A charming plant, forming dwarf dense tufts, and covered with large heads of flowers, which are bright blue with a yellow eye, and produced in such profusion as to hide the foliage. This is not the *M. alpestris* of gardens. It is delightfully fragrant in the evening. Division.

TRITONIA AUREA.—This forms a beautiful orange group. Roots.

ANEMONE JAPONICA, *HONORINE JOBERT*.—Flowers large, white; foliage handsome. Forms a fine bed for autumn flowering. Division.

The above are all of acknowledged merit for bedding purposes; and, with a number of beautiful annuals that can be raised from seed in spring without much heat, and ornamental plants specially adapted for planting singly on lawns, we can be more independent of tender plants than we imagine. In addition to those named, it is probable that many handsome plants may have escaped my notice, and of such I shall be glad to hear.

G. ABBEY.

ORCHARD-HOUSES IN GUERNSEY AND IN HERTS.

In common, I hope, with the greater number of your readers, I have derived much pleasure from reading Mr. Bréhaut's articles on his orchard-house. If he will kindly make them a sort of journal as to the periods his different kinds of fruit ripen in his sunny climate he will add to our pleasure, as we shall then be able to compare notes.

He mentions his having gathered ripe Early York Peaches ever since the beginning of the present month—let us say for the sake of a date the 7th. It is now the 19th, and my only ripe Peach is the Red Nutmeg. The Early York, and Early Victoria its child, are only just changing colour. I must, however, state that my house is span-roofed, 100 feet by 24: Mr. Bréhaut's house, if I recollect rightly, is a lean-to with a brick wall at back. This will, I think, make a difference of a full week in ripening power.

Apricots are now ripening, but the little Early Sardinian is, however, just over. It is rather dry, but a perfect sweetmeat. The Early Moorpark and Oulins Early Peach are now fully ripe and of great excellence, the juice running from them in a stream when they are bitten.

I have never seen anything in fruit-culture more beautiful than my Apricot trees this season—pyramids studded with golden-ball-like fruit from head to foot, and large bushes, now upwards of twelve years old, so loaded as to compel us to support their branches with string. On two of these fine old trees are 260 fruit, of a fair medium size and of most excellent flavour.

More interesting even than these fine trees are some seedling Apricots some five years old, not more than 2 feet in height, yet weighed down by their crops. To show the improvement that may take place in raising seedling fruits, I may mention that one from that old variety—the oldest and earliest of our varieties of Apricots—the Red Masculine, has, by being crossed with the Peach, given fruit as early as its female parent, the Red Masculine, but more than double the size, and equal in flavour to that finest of all Apricots the Peach. Seedlings from the Large Early are so much like the parent as not to be distinguished from it. Seedlings from the Kaischa are most remarkably productive, and one amongst them some ten days earlier than its parent. The facility of raising seedlings, seeing them bear fruit after only a few years of care, and closely watching all their peculiarities, make the orchard-house a pomological paradise to the experimental and reflective gardener—in short, to such men as Mr. Bréhaut.

The Honey Peach, which I remember sending to Mr. Bréhaut a few years since, is a Chinese variety, with curious pointed fruit and a most luscious sweetness. I received it from Mr. Charles Downing, the American pomologist: it will probably give us a new race. The Canary Peach is from Georgia, U.S. It is not early here, for I observe that my fruit are not yet changing colour, while those mentioned by Mr. Bréhaut ripened July 11. This shows most forcibly the warmth of his orchard-house climate, and one almost feels a little envy. Still there is in all worldly matters some compensating influence. I have thousands of trees, but not a spidery leaf on them—all are green and flourishing. The greater portion of my trees have been closely pinched in to three, four, and five leaves, all the summer. I may add a useful hint to Mr. Bréhaut's excellent instructions. Many of my trees have compact round heads, masses of luxuriant foliage, and incipient blossom-buds. I have had them looked

over carefully by my orchard-house manager, and many shoots cut out with a sharp knife, so as to open the head of the tree to the influence of the sun and air.

Mr. Abbey in one of his articles (I cannot give him credit for much orchard-house practical experience), invites me to send orchard-house Peaches to Bradford, to test them with wall-grown Peaches there. Now, any fruit-gardener well knows that Peaches packed from twelve to twenty hours lose all their fine aroma. A really fine-flavoured Peach is seldom tasted in Covent Garden. My method for several years past has been to gather some Peaches from my trees in pots, to take them to my neighbour's fine Peach wall, to place them on a table in front of the wall, and then to test them with Peaches of the same kinds freshly gathered from a wall tree. I have always beaten my neighbour, my Peaches having more succulence and flavour. If Mr. Abbey wishes his orchard-house communications to have the least weight he must not any longer be a stay-at-home writer.—T. R.

STRAWBERRIES.

THE Strawberry season here is now over. The Alpines were cut down about the 6th of July, in the hopes of some Strawberries in September. These with plenty of sugar are a delicacy, and a good accompaniment to Sherry, or Rhenish wines. They are also delicious with sugar and cream. They should be in every garden. The difficulty is to keep them back till other kinds are over. Probably spring-removal would help to check their early flowering. I keep only the old white Alpines, which, I think, are better than the red. After cutting them down, I manured them highly, and have kept them well watered, and I shall see with what result. If size is wanted, they should be occasionally raised fresh from seed. This is the main reason why newly-raised Alpines are larger than the old sorts. The red and white-bush Alpines, which have no runners, but are propagated by seed, and also by division of the roots, are the largest that I have seen, and great bearers, when newly raised by seed; but the fruit loses its size by or after the third year. The plants in the second year, under high cultivation, are as high as a man's knees, and look like Horse-Chestnut trees. They will bear a little fruit the first season of their growth. Had I appliances for raising seedlings, I should assuredly keep them.

I do not believe that the Strawberry season has been good for some sorts, or for lazy people who will not pump; but I have had a glorious season. I like a West Indian sun, and plenty of pump water, both for Roses and Strawberries. The Queen, and other Strawberries known to be great bearers, in the fine lands of Blandford have been a total failure. In torrid summers the fine sorts suffer most. I have had "*nil*" from my Scarlet Pines.

The Strawberries that I have recommended have done gloriously. The crops were huge of these—viz., Eliza (Rivers), Royal Hautbois (Rivers), Frogmore Late Pine (Ingram), Empress Eugénie (Knevett), Wonderful (Jeyes), Marguerite (Lebreton), Bicton Pine (Barnes), and Boisselot Seedling No. 1, now called La Vineuse, a very good hardy plant, handsome, heavy cropper, uniform in shape, and of good flavour—latish. These are a good lot of Strawberries, and can be recommended safely. My old friend Trollope's Victoria did not come out so well as usual. Eclipse, the best early Strawberry, finest in flavour of the early sorts, and President, a very fine and good early Strawberry, were in single file, and though netted could not escape the hungry blackbirds and thrushes. They may be safely added to the top lot. They would have done well if let alone.

I have had other sorts, which are good as plants, and heavy croppers; but they have not been sufficiently meritorious to name them. The following are partially tried, and I believe that on further trial they will be found to be very meritorious—viz., John Powell (Ingram), Lord Clyde (Dean), and Lucas (De Jonghe). These three Strawberries are the best of the novelties, that have been here for some time. They appear to be worthy of particular description. John Powell has been well and—excepting that I cannot state its mode of growth—rightly described in THE JOURNAL OF HORTICULTURE by the Editors. It is of an uniform coned shape, firm, solid to the centre, of good quality of flesh, juicy, and fine-

flavoured. I cannot at present say whether it will be a cropper, and suited to various soils and situations, and also to divers seasons—all important points. Lord Clyde is a strong grower and cropper, and sure to be a great favourite. It is very sweet, juicy, and fine-flavoured. I think that taking all points, plant, cropping, flavour, and adaptation to varying circumstances, it is one of the best sorts that have been submitted to me for some years. Lucas is a relative of La Constante and Bijou, but a better grower, and does not, like them, burn in torrid weather. It is a good cropper; and, as regards flavour, is in the line of La Constante. It is of good uniform shape, and not so slow to run as the above Strawberries.

In our precarious climate, early running and early establishment are very important. In land peculiarly adapted to Strawberries, and lying well to the sun, they may be planted later for next year's cropping than they can be planted here. An impostor, on being told by me that I would give him nothing, remarked, "Well, sir, you could not give me less: there is no taste in nothing, that I ever heard on." The Queen-growers have found out this; and no less a person than a coroner gave me a verdict. "Ah! what you wrote about Eliza was true. That is the Strawberry for me!" I have purchased a good degree in this county by recommending Eliza, Wonderful, Eugénie, and Frogmore Late Pines. Add the Royal Hautbois, and you see my five best Strawberries. The last two are great leaps.—W. F. RADCLYFFE, Rushton.

MY ORCHARD HOUSE.—No. 6.

SITTING in my orchard-house, my custom when the afternoon is cloudy, I was forcibly struck by the various shapes many large trees had gradually assumed. This was the result of growth, and as the building had, meanwhile, remained the same, much overcrowding had arisen. The shapes were altered, too, much for the worse, and would have shocked a theorist. The trees were heavily, too heavily, laden, nevertheless the unpleasant fact remained, that all symmetry was gone for this season.

This is by no means the first time that a doubt has arisen in my mind as to whether we really have the best form for orchard-houses—that is, for those houses which, like mine, are approaching to their eighth season of work. One thing is evident, that those low structures, with sunken paths and narrow dimensions throughout, can never suit for trees twelve years old, in whatever form they may chance to be trained. These houses have done a good work, and done it fairly; they may even be extremely useful for rearing young trees for succession, and also to receive any tree which, from over-bearing or otherwise, requires a year or two of rest; but they cannot meet the wants of a more advanced period of work.

Orchard-houses being a great fact, and certain to be largely built in the future, it is of the highest importance to consider the best form they should take. Much profit would result to us all if this subject could be discussed fairly and temperately. For example: it is well known that lean-to houses are warmer and earlier than span-roofed houses; and therefore should be built, in preference, in cold localities. Then span-roofed houses offer many advantages peculiarly their own—such as being loftier at the apex, and thereby giving us space for trees grown as standards, with bare stems, to raise themselves, and nothing can surpass the beauty of this class of tree if properly trained. Span-roofed houses are more light and airy; and indeed I am convinced that potted trees should be turned towards the sunny side of the house several times during the season. In this way the fruit is more highly coloured, the shoots sooner ripened, and the leaves far more healthy. But span-roofed houses have, of necessity, no back walls, whilst these walls, if covered (as is the case with my own house, which is a lean-to), with cordon trees planted at intervals of 3 feet, trained at an angle of 45°, and the whole closely pruned, it is impossible to imagine a better way to produce handsome fruit. Retaining, then, a back wall for this purpose, why should not a span-roofed structure start from the centre of this part at right angles to it, and the whole building assume the form of the letter T? By this combination much is gained, as is evident. The upper portion, being a lean-to, and not less

than 12 feet high at the back, the earliest and most choice trees could be kept there, while the lower part would suit admirably for lofty trees, and such as grow freely, and are destined to come in later in the year.

I should also strongly advise amateurs to build their houses as wide as possible, because a clear path is needed round the front to prune the trees, and especially to gather the fruit without knocking down any from the surrounding trees. My own house being very crowded causes us much trouble in this way, and the loss of fruit is something serious.

The time will come when our present houses will not suffice. The trees will become large and spread out, and if we continue season after season to overcrowd, our fruits will soon come to "their bitter end." We shall soon require two or three houses for our work, and possibly find it to our advantage to have one of these entirely devoted to resting one-third of the trees each year. Another small house will be needed for our young stock, and, perhaps, separate houses for Cherries or Apricots, which are impatient of confined air. All this we may be coming to, and long, wide, and lofty buildings for our main crops too; but our gain will be proportionately great.

This year the birds have left us little worth having out of many good things. Our Apricots have been long dismissed from out-door cultivation. I took the common standard Apricot of the Touraine, which there bears like an Apple tree, and which, also, near Paris is daily seen loaded with fruit, and, after many attempts, failed to make it bear against a sunny wall. The more delicate Plums are uncertain out of doors here, and of Cherries we could not save any. Of Early York Peaches none remain. This sort bore from the 4th to the 25th of last month. There is no early Peach equal to it. The Honey Peach from China is a remarkably pointed Peach, like an almond. Ripe on the 20th. Its flavour was quite peculiar. It was pale and about the size of the Early York. We have gathered about two hundred fruit already from the house.

The high winds which prevail in this island and the cloudy sky are not favourable to fruit culture. The currents of air shake down the ripening crops and cause us loss.—T. COLLINGS BREHAUT, Richmond House, Guernsey.

GOOSEBERRIES—RAISING SEEDLING FRUITS.

My thanks as one of a thousand who welcome right heartily the attention bestowed in your last Number on the homely undervalued Gooseberry. Filling up the gap between the latest of our Strawberries, that are palatable without the addition of sugar, and the earliest Jargonelle, it has a value in out-door fruit-culture which its unfailing excellence and certainty in cropping have led us all too much to forget. Your notice of the doings of the revived Fruit Committee of the Horticultural Society must have opened the eyes of many lovers of a good Gooseberry to a progress in connection with this fruit of which they were altogether unaware. I write now to know more of what is almost all new to me.

Some six years ago I made a collection, numbering upwards of a hundred sorts, of every Gooseberry within my reach, which either the Catalogue of the Horticultural Society or nursery lists classed as first-rate in flavour.* Year by year I have weeded from these the less worthy, till, with a selection of scarcely over a dozen distinct kinds, I have a really fine plantation, whose produce I would not exchange for any other fruit in the garden. Somewhat to my surprise, of the long list of good, and tolerable number of extra-flavoured varieties which the Fruit Committee selected, all, with the exception of perhaps half a dozen, are novelties, occurring neither in the Society's Catalogue nor in the nursery advertisements. I hope they are comeatable by others than the Fellows of the Society. Can you help us to the whereabouts? for though on the border of Lancashire and Cheshire, none of our nurseries here have any but the stereotyped list, which the London trade have scarce altered for the last ten years.

For this progress in fruit culture, it would seem, we are entirely indebted to the humbler population of this district, who, whilst aiming at little else than increase in size, stum-

bled, as it were, on something far more valuable. What might we not look for, and not in the Gooseberry only, from well-directed imitation of the good works of these real cottage gardeners? I have sometimes, whilst mourning over the flavourless burlesques of your south of England Golden Pippins, which our northern orchards produce, wished to see a Seedling Fruit Society started, with the JOURNAL OF HORTICULTURE as its organ, embracing the whole country in its operation, to further the production of new native varieties of our hardy fruits. I would have just one qualification of membership, the *bona fide* sowing of a minimum of one hundred seeds per annum, the seedlings therefrom to be reared till fruiting, and samples of the material results forwarded for commendation, or otherwise, to the Journal's Pomological Editor. Is not something of the kind practicable? See what one man has done for the Strawberry. What would this delicious fruit have been but for Myatt and those who have, not too late, followed in his steps? Not to speak of Knight and Williams, and our Belgian pomologists, to how much are we already indebted within a year or two back to the quiet labour of Mr. Huyse? (By-the-by, you promised us, so far back as January, a paper on the Huyse Pears, for which I have looked very often in vain.) Experience would seem to indicate that out of several thousand seedlings a few splendid prizes are almost a certainty. A society for the special purpose might fruit fifty thousand every year with a very little effort. Say the word, Shall we begin?—FRUIT-EATER.

BEDDING GERANIUMS.

(Continued from page 72.)

THE next best system of raising a supply of bedding Geraniums is to place a cold frame in an open situation so that the lights may face the north, previously laying down a layer of rough ashes from 3 to 6 inches thick for the frame to rest on, and to keep out worms. Place within it 6 inches of compost formed of turfy loam one-half, leaf mould one-fourth, and river sand one-fourth; and having made the surface level, put in the cuttings in rows 3 inches apart, and 2 inches from cutting to cutting in the rows. This done gently, press the soil round the cuttings, giving a gentle watering afterwards to settle the earth about them and to refresh the foliage. The lights are then drawn or close, and kept closed for a period of a fortnight if hot dry weather succeed the operation, opening them only for the purpose of watering, which should be done so as to keep the soil constantly moist but not wet. Should dull weather follow, the frame may be opened for an hour or two in the morning to afford a change of air and to prevent damp; but if all be well there is no necessity for this, nor for shading the frame unless the air be hot and dry. In the latter case a thin mat or two placed over the frame at 10 A.M., and taken off again at 3 P.M., will be all the shading needed; for, owing to the frame sloping to the north, more than half of the sun's rays will be reflected by the glass, hence there is not that searching heat that there is in a frame facing the south. The cuttings will be rooted in three weeks, when air may be admitted, moderately at first, gradually increasing the openings daily, so that the lights may be removed altogether in seven days more, or a month after the cuttings are put in. The frame may then be removed altogether and placed in some suitable situation, and the process repeated on another lot of cuttings inserted in it by the 1st of September; but this time the lights should slope towards the south, for we must now endeavour to catch as much of the sun's heat as possible.

The cuttings struck by the 1st of September will be nice plants by the end of that month, when they may be potted into 48-sized pots, or 60's if small plants, and be placed in a house with a greenhouse temperature; but if room be scarce it may be worth while considering whether it is better to pot the plants or transplant into boxes, which will hold double the number in something like one-third the space. Strong plants, however, in my opinion are best potted at once; but such as are only just rooted may be wintered in boxes much more economically as regards space. The boxes used for this purpose are those narrow shallow ones such as we very often see employed for growing Mignonette for

windows, and are 4 feet long, 6 inches wide, and 4 inches deep, and will hold four dozen plants each. In filling them begin at one end, and after placing 2 inches of rather rough compost at the bottom of the box, put the first plant an inch from the end and side in one corner; then two more plants, one in the opposite corner like the first, and the other plant in the centre. Put the soil neatly round these, and then put in another row 3 inches from the first, and so on to the end. The plants are then well watered and placed on a shelf, or in any light airy situation from which frost is excluded. In April they are transplanted into cold frames with a ball of earth to each, and about 3 inches apart every way, the lights being kept close for a few days to encourage root-action; afterwards air is admitted daily and water given, and they ought to be well hardened by the third week in May, when they may be taken up with balls and planted in their final quarters. It should be borne in mind that if severe frosts occur some protecting material is necessary to be placed on the frame at night. The points of the shoots should be nipped out to make the plants bushy: this ought to be done in March, before the plants are transplanted into the cold frame.

Though the above systems answer very well where there is a greenhouse, yet there are those who have not such conveniences; but even they may have their hundreds of Geraniums. To accomplish this is not difficult; for if cuttings be taken early in August, and inserted in the open ground in any light soil to which a little leaf mould and sand has been added and the whole well mixed, they will strike root quite as freely as pieces of Dock roots, if the soil about them is kept moist and a little shade afforded from bright sun. By the middle of September these may be taken up, potted into 60-sized pots, and wintered in a greenhouse, potted in March into 48's, stopped a week afterwards, hardened off by placing out of doors in turf-pits in April, and protected from frost by mats or other covering. Where no greenhouse exists boxes about 3 feet long, 6 inches wide, and 3 inches deep inside measure, should be provided, and a few holes bored in the bottom to allow the water to escape. On the bottom of each box 1 inch of the rougher parts of the compost should be placed, and then an inch of fine compost, consisting of turfy loam three parts and leaf mould one part, with a free admixture of sand. Into this box the cuttings are put in as close together as possible without actually touching each other, soil being placed around them neatly, and to within half an inch of the upper edge. They are then watered, and placed under a hedge, wall, or in some other warm sheltered situation.

When frosts sufficient to cut off Dahlias and other tender plants in open situations occur, the plants must be removed in-doors. Any spare room will do providing there is a window to admit light and air; but as very few have a room to spare, the boxes may have to be placed inside on the window-board, but if there be no such support, or if there is danger of injury to the window-boards, neat iron brackets may be used for placing the boxes on, whilst a loose bottom will do all that is necessary to preserve the window-board. In such situations the greatest care is necessary not to overwater the plants, but to keep them dry at the root, and give no more water than is just necessary to keep them from losing their leaves. If the windows have a southern aspect it will be all the better, for an hour's sun will suggest the possibility of giving a little air, which in mild weather is best done by placing the boxes outside on holdfasts driven into the wall, where they will enjoy the fresh air, and the heat of the sun reflected by the wall. Whenever the temperature permits of their being placed outside, it should be done, always taking care to remove them inside before the air is cooled down to freezing-point. When very severe weather sets in, and the plants are likely to be frozen by their close proximity to the window, even if shutters be employed, it is easy to remove the plants to a secure place, as a kitchen, at night, and in the day also until such time as the weather changes, when they, of course, may be returned to their proper quarters. If brackets are provided, there will be no necessity to remove the boxes, but only to take them down until the shutters are closed, when they will, of course, be placed on the brackets again, and the plants will sustain no injury if a fire has been in the room during the day. Now, with a box of plants in every window, or some

of them, a nice stock of Geraniums may be safely preserved over the winter.

When the days are getting longer the boxes should be placed on brackets or holdfasts in the south wall daily by 8 A.M., when the thermometer exceeds 40°, and be taken under cover by 5 P.M., and this treatment must be continued daily (weather permitting) until the beginning of April, when the plants, after remaining stationary during the winter, will be showing signs of growth. If turf can be had in sufficient quantity to make a wall round a square bed 6 feet by 4 feet, we have only to choose a warm, sheltered, open situation, and to form a sod wall 1 foot high in front, and 18 inches at the back, with ends to suit, so that there will be a gentle slope from the back to the front. Within this 3 inches of leaf mould is placed and worked into the soil about 6 inches, and if the soil be light and sandy it is all the better, but if it be heavy an inch deep of river sand spread over the surface and well worked in, will much improve the staple. Taking the plants up with balls out of the boxes, plant them in the turf-pit in rows 4 inches apart, and 3 inches asunder in the rows. Give a gentle watering, and if any old lights are at command place them over the pit, but if not, sticks must be used to support some protection such as mats. The covering should vary in thickness according to the state of the weather, be put on early in the evening, and remain on in the morning until the sun has subdued the frost, and the air becomes warm; but should the frost continue all day do not remove the covering, for the plants will not be injured by being kept in the dark, if they do not grow. What watering is required should be given in the morning, so that the plants may be dry before night. As the weather becomes warmer the plants will grow rapidly, and must, therefore, be well supplied with water. They will need no protection except from frost. By the beginning of June they will be fit for transplanting into the flower garden, taking them up with a ball, having previously trodden between the rows and given a good soaking of water.

By this simple treatment some nice beds may be furnished with the hardier kinds of Scarlet Geraniums, as Crystal Palace Scarlet, Lady Rokeby, Little David, Tom Thumb, Trentham Scarlet, Spitfire, and Christina. These with most of the Zonale and hardier kinds of variegated Geraniums will strike out of doors quite as freely as under glass, only they are longer in doing so. Most of them require to be put in by the second week in August at the latest, or they will not root well. Some of the better kinds of scarlet and variegated Geraniums will not do any good under such treatment, it being at the best a precarious method, and it should never be resorted to unless other means are not at command. Cuttings of most Geraniums, however, will strike root in the open air if inserted from the 1st of June to the second week in August, after which they must be placed under glass.

I now come to the most pleasant part of the business, for I have to treat of the propagation and preservation of old plants under glass or otherwise, but I must leave this for another communication.—G. ABBEY.

(To be continued.)

CHICKENS VERSUS GREEN FLY.

I AM anxious to add my testimony to that of "WILTSIRE RECTOR," in your Number of July 19th, with regard to the utility of chickens in a garden. This year my Peas, as everything else, have been covered with blight, and I have many times seen the chickens, perched upon the Pea sticks, eating the green fly as fast as possible, and when my man is picking the Peas, the chickens follow him, and so surround him that he is in constant fear of treading upon them, in order to seize on the green fly as they are dislodged by the shaking, and fall to the ground. My experience is, that up to six weeks old, chickens do much more good than harm in a garden.—A. K. C.

ORCHARD-HOUSE PRODUCE.—I hasten to correct an inaccuracy in the statement I made in last week's Journal relative to the sale of Peaches and Nectarines in Covent Garden from my orchard-house: instead of 80 dozen in five days, I find from my gardener's account there were only 71 dozen, and that 42½ dozen have been since sold.—AMATEUR.

BEST OF THE NEWER ROSES.

It is due to Mr. Murray to say that he wrote to me on the subject of the lecture (date July 11th), but directed it to Congleton. It went to Rushton near Leek, and Rushton near Kettering, and hence arrived too late here. To prevent mistakes in future, letters to me should be directed to Tarrent (corruption of Torrent) Rushton, near Blandford, Dorset. There was formerly a wealthy family of the name of Tarent in this county. It is not improbable that the prefix was derived from them.

I have read "D," of Deal's two interesting Rose communications. His descriptions are very good. There is one Rose, Madame Julie Daran, that he is mistaken about. It has but one fault—it wants fixity of colour. It is perfectly full to the centre, of fine outline, with smooth well-disposed petals of great substance, and blooms abundantly. The growth and foliage are admirable. It is one of the fullest of its year.

Perhaps it may assist nurserymen and amateurs if I give a list of the newer Roses worthy of propagation.

1. Charles Lefebvre, Duc de Rohan, Maurice Bernardin, John Hopper, Prince Camille de Rohan, Madame Julie Daran, François Lacharme, Maréchal Vaillant, Madame Boutin, Professor Koch, Madame C. Wood, Madame Clemence Joigneaux, Alphonse Damaizin (smallish), Sœur des Anges (occasionally magnificent, but often cracky, or unilateral), and Olivier Delhomme, not a strong grower. Mr. Cant's trebles of Monte Christo were extra beautiful on June 29th. It is suitable only to first-class lands, and requires more looking after than the above.

2. *Roses of 1862.*—Alfred de Rougemont, Baronne Adolphe de Rothschild, Madame Freeman, Vainqueur de Goliath, President Lincoln, Madame W. Paul, Mr. W. Paul, Baron de Rothschild, and Le Rhône, not a sturdy grower.

3. *Roses of 1863.*—Lord Macaulay, a fine Rose of great substance, endures sun well—A1. Lord Herbert and Lord Clyde I only know by the sight of their blooms. They appear to be Roses of great excellence. Mr. W. Paul kindly sent me buds of Lord Macaulay, Princess of Wales, and Lord Herbert. The buds have taken, and are growing freely. The wood sent was strong. I cut up my plant of Lord Clyde (apparently not a very strong grower), for the same purpose. It took immediately, and is growing freely. Mr. George Paul's specimens of it at the lecture-room were grand. Mr. W. Paul also exhibited fine specimens of Lord Macaulay and Dr. Lindley, a good Rose of great substance.

In conclusion, till we get Roses on strong stocks we can only approximate. All the above Roses, not excepted to, are good growers, hardy, and beautiful. These are good useful Roses for the garden:—Duc de Bassano, Peter Lawson, Vicounte Vigier, and Madame Alfred de Rougemont. They are good growers and hardy.—W. F. RADCLYFFE, *Tarrent Rushton.*

GARDENING UNDER DIFFICULTIES.

I USED to imagine, in looking back on some of my gardening experiences, that I deserved some little credit for the manner in which, at certain periods of my horticultural experience, I had surmounted some difficulties. For example, when on the top of a cliff overhanging the sea I used to have flowers the admiration of the neighbourhood, or in a small back yard in a confined street of a fashionable watering place I managed to grow some creditable specimens; but what I have seen lately induces me now to think that I have had no difficulties, and that they were only the effect of a disordered imagination. It may be useful, perhaps, for those "Constant Readers," "Subscribers," &c., who are oftentimes sorely puzzled because their Scarlet Geraniums are not all of a height, or that their Hyacinths will not grow if they plant them upside down, and who want to know why the wind will persist in blowing off the blooms of their Roses, to record what I have seen lately of gardening under difficulties in the west of Ireland.

I have not visited these regions (for this is written on the very borders of the Atlantic in Donegal), for thirty years; but even then I knew something of flowers, and can appreciate now the change which care and time have wrought. No one can have any conception of the opposing elements

in these regions. It is not that the soil is at fault, for in many places it is good, and can be made so; but the awful hurricanes that sweep along, and the continuous rains, are something that we in our southern counties know but little of.

In Achil, a gentleman of the name of Pike has built for himself a commodious house, where he dispenses an open-handed and generous hospitality, and where he has fairly combated and beaten the elements. His difficulty, and indeed the difficulty all along this coast, is to beat out the westerly gales, and consequently plantations must be made at some distance as a fence; and when they have grown up a little, then more tender trees, shrubs, and gardens may be arranged. Thirteen years ago there was not anything higher than a Heath near his house, now plantations are rapidly rising up; and his garden was well supplied with various fruits and vegetables. Abundance of Cherries (though, I am bound to say, not equal to our Bigarreaus), Gooseberries, Currants, and excellent Strawberries were found there; while Fuchsias formed bushes as large as Laurels, and various herbaceous plants, Roses, &c., enlivened the gardens. Here, of course, a lady's hand was visible, and well was she rewarded for her pains. I saw two Wellingtonias about to be planted, but I fear they will never attain very gigantic proportions; but the *Pinus maritima*, of which the proprietor had received a quantity from Lord Palmerston, promised to be a very valuable tree, as it withstands the sea breezes so well. From its proximity to the sea there is one advantage gained—that frosts do not so easily affect things as they do in more inland situations. At Cliffoney in Sligo our noble Premier has made a laudable attempt to induce the peasantry to have a little more care over their gardens, and has striven to encourage a love of flowers. He has a large space enclosed, which is called his lordship's garden; and in this his steward cultivates some of the more hardy herbaceous plants, Phloxes, Delphiniums, &c., as well as Roses and shrubs, and distributes these amongst the people. Their little front gardens are enclosed with walls, and in these their flowers, &c., are planted.

I am sorry to say, however, that the cocks and hens, which form the invariable accompaniment of every cabin, wage deadly war with the flowers, and the results are not such as his lordship would wish. It was very curious here to witness the effect of the westerly gales: where a thin hedge had been planted, not only had the trees received a bias towards the east, but there was not a single leaf on the westerly side, while they were completely arched into green arbours, the foliage all being on the easterly side. Again, in this place (Gweedore), an hotel for the convenience of travellers has been built by Lord George Hill, in a gully (for it is not a valley), into which the whole force of the westerly winds sweeps. To this hotel there is attached a garden, and in it there is a very good assortment of hardy plants, which are thriving well, while the Mignonette, Nemophila, &c., enliven it.

Oh! ye thick-and-thin advocates of the bedding-out system, what would ye do here? or how could a garden like this be supplied but for those "rubbishy" herbaceous plants, which are now not considered good enough for our gardens? Twenty years ago there was nothing but Heather and bog in this place; I saw now in the garden as good crops of vegetables as one would wish—late Marrowfat Peas, Raspberries, Currants, and Strawberries, while the staple commodity, the Potato, was flourishing. All this surely shows what can be done by perseverance. I should add that I have never seen *Cotoneaster microphylla* in greater luxuriance and abundance; and I have little doubt that, were time to be bestowed, many a pretty flower might be induced to bloom; and what noble ferneries might be made here! I saw a plant of *Osmunda regalis* growing on the roadside to-day, and many fine plants are to be found in various localities in the neighbourhood.

These few notes are somewhat out of my ordinary course, but they may be useful in leading some to see that their difficulties are hardly worth mentioning when compared with such as these, and also may encourage some who might think that they are too unfavourably situated to attempt anything; and it is to be remembered that these are not the efforts of professed gardeners, they are done in a quiet farmer-like way, and I have no doubt that were a little more

care and attention to be bestowed that much more might be effected.—D. Deal.

P.S.—The following will give an idea of what can be done in a wild country by a patriotic landlord, such as Lord George Hill:—

STATE OF GWEDORE IN THE YEAR 1838.	STATE OF GWENDORE IN THE YEAR 1856.
The roads and bridges in existence at this period few and scarcely passable.	Roads and bridges numerous, and in excellent condition.
No carts used.	Thirty-two carts.
The land held in common, or rundale.	Almost every tenant has his farm to himself. In 1841-43 the estate was surveyed, valued, mapped, and the farms divided.
Constant quarrels and litigation as to trespass.	Petty sessions every fortnight, and very little business.
No progress in agriculture.	600 acres reclaimed since the land was divided into farms. Flax, Turnip, Clover, and Grass seeds sown in small quantities.
No post-office nearer than ten miles.	Three post-offices, and a daily mail car, in the Gweedore District.
A very primitive corn mill, neither capable of cleaning the corn, nor of sifting the meal; and none superior to it within thirty miles.	A first-rate corn mill, with kiln attached. This mill, which was completed the year of the famine, worked then night and day, and ground 688 tons of Indian corn.
No baker, nor bread sold within ten miles.	An excellent baker, whose sales amount to upwards of £200 annually.
No market for produce.	A large corn store, at which more than 130 tons of oats were purchased last year for exportation, and to which eggs, hides, fish, butter, and kelp, are brought in large quantities.
Nothing like a shop in the district.	An extensive shop, at which all necessaries can be purchased at a reasonable price.
No medical man or dispensary within ten miles.	Dispensary, and weekly attendance of a medical man.
No Protestant church, burying-ground, or clergyman within ten miles.	A school-house, licensed for Divine service (congregation averaging fifty persons) a Protestant burying-ground, and a resident clergyman.
Only three houses in which lime had in some measure been used in the building; others all dry masonry, or stones laid in mud.	More than 250 houses, in which more or less lime and whitewash have been employed.
No hay could be purchased nearer than twelve miles.	Model farm at the Gweedore Hotel, producing from 50 to 60 tons of hay.
No inn, or decent house, in this part of the country, in which a person could put up for the night.	Gweedore Hotel, much frequented by tourists, and from which the mail car starts every morning at 10 A.M., and returns at 3 P.M.
But little butter fit to eat, and in small crocks.	Good market butter, put into wooden vessels.
Not a boat-pier on the coast.	Quay and landing-place at Bunbeg for vessels of 150 tons.
Anchorage under Gola Island and in Gweedore Bay unknown.	Vessels can now be chartered for Bunbeg and Gweedore from any other port; and the anchorage is properly buoyed.
No trade or home manufacture.	Kelp is shipped from Bunbeg. In 1854, Gweedore hand-knit socks and stockings were sold to the amount of £600; and in 1855 to the amount of £500, during the Crimean war.
Rent irregularly paid, and difficult to collect; amounting to about £500.	Rent regularly paid.
Arrears upon the property, £1000.	Arrears under £10.
The good-will or tenant right received by those who sell their farms varies from fifteen to thirty years' purchase.	The amount given for the good-will of a farm is upon the increase, the competition for land being very great.
It is a remarkable fact that there is scarcely any decrease in the population of the district since 1846.	No. of cattle belonging to tenants, about ... } 1700 head. No. of sheep belonging to tenants, above ... } 4000 " No. of horses belonging to tenants, about ... } 300 "

NOSEGAYS.—Flowers should not be cut during sunshine or kept exposed to it afterwards; neither should they be kept in large bundles and tied tightly together, as this invariably hastens their decay. When in the room in which they are to remain, the ends of the stalks should be cut clean across with a very sharp knife (never with scissors), by which means the tubes through which they draw the water are left open, so that the water ascends freely, which it will not do if the stems are bruised or lacerated. The stalks should be inserted in pure water. This water ought

to be changed every day, or once in two days at the farthest, and a thin slice should be cleanly cut off from the end of each stalk every time the water is changed, which will revive the flowers. A glass shade preserves them remarkably.—(Farmer and Mechanic.)

WATER AS AN ORNAMENTAL FEATURE.

WATER!—clear and sparkling water!—what pleasing ideas are conjured up by its name, more especially in the hot dry weather of the dog days! And the sun-scorched mariner, ever and anon becalmed under the broiling sun of the tropics, with but a very limited allowance of this fluid in a state fit for his use, recalls to memory the sparkling streams of his native country. The poetical allusions so often met with in Holy Writ, place “streams of water” as the most important features of those lands having more than an ordinary share of Nature’s blessings; and in all countries water is esteemed one of the greatest boons. Many an arid waste owes its barrenness to the absence of this all-important fertiliser; while in districts where its amount is inadequate to the wants of the inhabitants very lamentable results are the consequence. The infant soon learns to dabble in water; in childhood the edge of a pond, river, or canal seems to be possessed of irresistible charms; and at a more advanced age the ocean receives its share of patronage from the more adventurous, while those less disposed to travel may often be met with in groups looking earnestly and steadfastly at every sheet of water they meet with. A solitary passenger rarely crosses over a bridge without looking over its side to have a peep at the stream below. Journies of scores, nay, hundreds of miles, are often taken to get a sight of some of those noble sheets of inland water with which our own and some other countries are blessed; and the purse of the affluent has often been widely opened to form some artificial feature in water. Indeed, it seems to be an element closely blended with all our ideas of what is beautiful.

In many places of the highest note water forms an object of the greatest possible importance, and next if not quite equal to shrubs and trees. The value of water may also be easily understood by the careful way in which it is economised. In most places of note water is made visible in some form. If a stream cannot be commanded a piece of still water is made to do duty; and now and then highly ornamented or elaborate works of art are devoted to its reception, but even without the aid of these it is at all times attractive, even in its simplest form. Let a visitor to Hampton Court but take the trouble to ascertain whether any portion of the beautiful grounds receives more attention than the circular basin of water with its gold fish. All classes seem to delight in gazing on the glassy or rippled surface of water wherever it may exist, be it as a noble river, a running brook, or a placid pond.

Water, therefore, may be regarded as a universal favourite; and considering that it is of such importance to the well-being of the community, we need not be surprised at now and then hearing of disputes where it is misapplied or its purity destroyed. Pure water is now admitted to be of as much consequence to the public as pure air. Its uses, however, for ornamental purposes in gardens are those to which I chiefly intend to confine myself, and I must pass over topics such as the above as being out of place.

Water being so essential a feature in all dressed grounds, there are few places where its introduction, at whatever cost, is not desirable, not only for its own sake but also for the display of the works of the architect and sculptor, and which otherwise it might not be possible to bring in with propriety. How much the noble gardens at the Crystal Palace would lose in public estimation if deprived of their fountain! Not less important are the cascades and fountains at Chatsworth; while the silvery Thames lends its aid to the noble grounds at Cliveden. Kew is perhaps less blessed with water than most public gardens, but the Thames runs by it, and a sheet of water forms a foreground to the view in one direction from the large Palm-house; lakes and borrowed streams are doing duty of a like kind in hundreds of other places.

Water as a feature in the landscape is so much valued that

its presence is courted at times, perhaps, when good taste might even question its being in character with other things; but these cases are comparatively few, as there are few places where it may not be appropriately admitted. Perhaps one of the principal objections to its use as an ornamental feature is where it cannot be had in sufficient quantity to keep itself clear. Muddy impure water is at all times objectionable, but it is questionable whether the plan of removing and destroying everything of a vegetable kind that exists in water is good; on the contrary, stagnant water is rendered more pure by the vegetation which is supported by it. Many a pond in an undisturbed corner is entirely covered over with duckweed, presenting a pale green surface completely hiding the water, and yet no hurtful effluvia arise. Nature in this case, as in many others when she is not hindered by officious hands, provides the antidote as well as the poison; and it is not until the ditch, pond, or watercourse is disturbed that any noxious vapours are diffused. A rank coarse herbage of other plants often accomplishes the same object, the rankness and vigour being in proportion with the quantity and quality of the food; so that our country friends living near stagnant pools have less cause to be alarmed in summer than they may expect. The vapours arising from wet, marshy, undrained land are quite different. The more exposed sheets of water are to the action of the winds the purer and better they will be, the moving mass being less likely to pass into a state of impurity than when it is less agitated. In many places of note the most important feature is water, and in some the duties water is made to perform differ in reality but little from those of the modern flower-bed—witness the beautiful form that ponds have been made to take in the exquisite grounds attached to the ruins of Fountains Abbey, at Studley Park, Yorkshire.

Water may be considered scarcely less necessary than trees and shrubs in a complete place, and I advise all who can command its services to do so ere the many water companies and others using it appropriate it to themselves. The present age seems as prolific in its demands for running streams and their diversion as that of the engineer Brindley. To make the most of such streams behoves the landscape gardener.

Water as an agent in the hands of the man of taste may be a suitable subject for another article.—J. ROBSON.

THE WANT OF VARIETY AMONG TREES AND SHRUBS IN PLEASURE GROUNDS

AND ORNAMENTAL PLANTATIONS.

THIS want, as noticed by Mr. George Gordon in your pages, is a most interesting subject, and one that requires more attention. How many plantations are formed without due regard being paid to displaying the natural characters of the trees. The planter cannot obtain much information at our nurseries relative to the best mode of employing the various species. The whole subject is one that requires much study and practice, and no man has had more practice as a planter of ornamental trees than Mr. Gordon, and no collection can be found in this country equal to that in the Horticultural Society's Chiswick garden, the growth of about thirty years. That collection is worth going a long way to see by those contemplating planting for ornamental effect.

A few days since I walked through the Chiswick Gardens with Mr. Gordon for the purpose of getting all the information I could about trees and planting, as I was about starting for the north of Ireland and north of England to lay out plantations for autumn planting, and I send you the description of the fine *Acer macrophyllum* in the arboretum at Chiswick, which he has forwarded me in answer to a query. At the same time I must inform those who go there without a guide to look up into the body of the tree for the label, otherwise, although the tree is distinct in character, they might have some trouble to find it.

I cannot conclude without expressing the regret I felt at observing the neglected state of the Chiswick arboretum.—JOSEPH NEWTON, 30, Eastbourne Terrace, Hyde Park.

"*ACER MACROPHYLLUM*.—In its native country the Columbia Maple forms a very large deciduous tree, exclusively

confined to the woody mountainous regions along the sea-coast, between 40° and 50° north latitude, and to the rocky base along the great rapids of the Columbia river in Northwest America.

"It was first introduced into Europe by the Horticultural Society's collector, Mr. Douglas, in the year 1827, and who stated at the time that it was one of the finest and most graceful trees in the country where it grew, varying from 40 to 90 feet in height, and from 6 to 16 feet in circumference in the trunk. Mr. Douglas also prophetically added that, 'it would at some future time constitute one of the finest and most ornamental forest trees in England.'

"The Columbia Maple is one of the most rapid-growing trees we have, as the fine specimen in the Chiswick arboretum proves. It was planted in the spring of 1828, and in seven years attained a height of 25 feet; while in 1845, or ten years later, it was 50 feet high, and now (1864), little short of 80 feet.

"The branches are numerous, wide-spreading, rather stout and straight, with the bark on the young trees very smooth and green, while that on the old ones is rough and brown. The leaves are sometimes nearly 1 foot broad, very smooth, of a bright glossy green, which in the autumn dies off to a yellowish-brown colour before the leaves fall. The flowers are produced in long, dense, finger-like spikes in April and May, just as the young leaves are beginning to unfold, and are of a yellow colour, and very fragrant. The wood is soft, beautifully veined, and in the specimens of the timber sent home from the banks of the Columbia scarcely inferior in beauty to the finest satin wood.

"The tree is perfectly hardy, and grows well in all soils and situations, and should find a home in every park and pleasure ground in the kingdom.—GEOEGH GORDON."

THE LATE JAMES FINLAYSON AND THE PAISLEY FLORIST CLUB.

SINCE the publication of your May Number, the oldest florist in the West of Scotland has been removed by death. The late James Finlayson, of Paisley, was in some respects a representative man, and a few words respecting him will no doubt be acceptable to your readers, many of whom knew him well. His simple and blameless life, as well as his devotion to the improvement and cultivation of florists' flowers over a long life of eighty years, are sufficient warrant for recording a brief tribute to his memory, and the horticultural journal of the district in which he resided would seem to be the most fitting place. He was hale and hearty, and keenly enjoyed his occupation among his plants and flowers, till death struck him down suddenly in the midst of his work, at the ripe age of eighty years. He was bending over his favourite flowers when he died. His old florist friends who knew him intimately, and with whom he had many a tough competition and tougher argument, will feel his loss keenly, and none more so than Mr. William Robb, who has himself reached the same age, and Mr. John Waterston who are now the two oldest florists in Paisley, and perhaps in Scotland. The trio belonged to the "Paisley Florist Club" in its early days, and many are the droll reminiscencies they could tell concerning it. The deceased Mr. Finlayson's father was Secretary of this Club, which was in existence as far back as 1782; indeed flower shows were held in Paisley previous to that date. Its origin however, cannot be traced, the earliest record-book having been burnt, for what seems to us the strange reason that the box of the Club would not contain the whole of the books and papers, and the old minute-book was destroyed to make room for books that were considered of more importance. Dr. Carswell, who first introduced the Carnation to the Paisley florists, was for many years a leading member of the Club, as was also Mr. Sharp, who has long rested with his fathers, and who was in his day a most successful florist. These departed worthies have left many pleasant memories in the minds of the few remaining old florists, who were at that time young men. Dr. Carswell seems to have been of a kindly, genial disposition, with a good deal of droll humour, which frequently found vent at the meetings of the Club. He did not like dressing flowers for competition—which, by the way, we had not thought to be such an ancient

practice—just imagine flowers being dressed eighty years ago. The worthy doctor called it "Thumbing" and told the weaver florists that their fingers took all the enamel off the petals and spoiled the flowers.

Long before Paisley was lighted with gas, the doctor had a gas-making apparatus for his own use; and as he could make more than he needed, he lighted one or two neighbouring shops. Gas was a novelty in those days. On one occasion he had been advised to try gas tar as a destroyer of a certain species of insect that sometimes infests the wood-work of old and even new houses; and when a florist friend asked him if he thought it would kill the domestic intruders, he said there was no doubt of that, for he thought the smell of the tar was going to kill the whole family.

But I must leave Doctor Carswell and the Old Club, and speak of the late James Finlayson. He is known to have exhibited Carnations in Edinburgh as early as 1815, and he is said to have gained his first prize for flowers in 1792, when he was only eight years of age. This may be correct in a certain sense, as he might have been exhibiting his father's flowers, but he could hardly claim the credit of growing them himself. For many years, and indeed up to last season, he attended most of the local shows, at which he was always in demand, but his great days were in connection with the Paisley Club. It was the custom to meet once a week, each member bringing whatever he pleased; the flowers were then laid out, judges appointed, and the awards made and entered in the records of the Club. On one occasion it was recorded, I think by Dr. Carswell, that "James Finlayson had the best Polyanthus, and he would have been a very bad florist if he had not, for it was the only one there." Money prizes were not thought of in the old days; the honour of being first was the only prize competed for by these primitive florists, and there is no doubt that their love for the flowers they cultivated must have been very strong. Mr. Finlayson was somewhat severe in his judgment of new flowers, and sometimes expressed his opinion with more vigour than elegance. When an Auricula called Dean's Delight came out many years ago he gave his verdict on it thus—"Tak' that by the cuff o' the neck and put it in the midden." He was a good hand at nursing seedlings: very few died with him, which gave rise to the saying that he was in the habit of putting warm bricks to their feet. His chief favourites were Carnations, Picotees, Pinks, Polyanthus, Ranunculus, and Auriculas, to which he devoted his whole attention on a small plot of ground in Paisley, for the last thirty years. Up to that time he had followed the occupation of a weaver.

Perhaps the best things he has raised are Auriculas John Bright, Richard Cobden, and Mrs. Beecher Stowe, which are said to be excellent varieties, and the two latter have never been sent out. Mrs. Beecher Stowe he said he would give to no one while he lived. He was very conservative of his plants at all times, and was very particular to get his price for those he sold. It was his practice to grow his flowers very fine—he disliked a coarse flower—and the result of growing in poor soil for the sake of fineness was that he seldom had much stock of choice or new varieties. He was an excellent judge of the flowers that were grown in the early days of floriculture, such as those he was in the habit of growing himself; but he maintained to the last that no improvement had been made in Carnations: he said they had more petals, but they wanted size.

He was much sought after by the working class for two mixtures, which either were in reality, or were believed to be, curatives of rheumatism and diseases of the eye. For these he never would take any reward. In his latter days his great pride was a walking-stick made of the stem of what is called a Clothier's Thistle, which he took great delight in showing and challenging people to tell of what wood it was made. He was one of the links that connected the present generation of florists with those who made pets of certain flowers in the olden time, and made the first efforts to improve them. The old Paisley florists, most of whom are dead and gone long ago, must have the credit of introducing florists' flowers to the West of Scotland, and of fostering that taste for them which is now spread far and wide. In this work the late Mr. Finlayson did his share. There are one or two old florists in Paisley who will, I dare-say, be able to give you some additional details, if you think

these few disjointed remarks wanting in interest; but there is little in the way of incident to be found in a calm and even life like that of Mr. Finlayson. He discharged the duties of his position with fidelity; so far as his means and opportunities went he promoted floriculture; but he has left his earth-born treasures to cross the dark valley, and the sound of his footsteps will be heard no more. "Life's fitful fever over, he sleeps well."—N. G. (*West of Scotland Horticultural Magazine.*)

WHITTLESEY'S LOCOMOTIVE SEAT.

We had the misfortune to have to do all our hard work in a generation when every plan for doing work easily was considered as indicating laziness. The locomotive seat would have had no chance of success in that day; but the wonders of the real locomotive have broken down all this prejudice, and such inventions as this of Mr. Whittlesey's cause the originators to be classed among the workman's benefactors.

The following illustrations explain the idea.

Fig. 1 shows the seat.

Fig. 2 shows it fastened to the foot.

—(*Gardener's Monthly, American.*)

Fig. 2.

VENTILATING.

I HAD a bricked dung-pit 10 feet long, 6 wide, and 3 deep; it was emptied out, and a glazed span-roof put on it; it runs east and west, so that the south side receives most of the sun. There is no upright side glass, but the roof consists of four sashes, two on the north side and two on the south. Either sash can fold back on its neighbour, and must be folded back for any one to get into the pit, there being no other entrance. When any sash is lifted it affords ventilation at the side, at top, and at bottom; when all four are tilted with a chock of wood it is as if the roof were off, except in the centre of each side of the span, where the sashes are hinged to work on. The pit is sunk and unpaved; it is damp; a number of Camellias and Azaleas have set their buds well in it. The south side of the span is all rough plate; the two ends are filled in with clear glass. After two o'clock some large trees keep the sun from the pit. Each sash is now tilted a foot, and the air travels freely through the

plants; there is no other ventilation. Will the Camellias do in the pit throughout the summer, or must they go under a north wall? At what time on a hot day should they be syringed? I could put tiffany over the east end and over the rough plate at the south side if necessary. I like the pit. Some of the Camellias and Azaleas are large plants, and they are protected from high wind and heavy rain where they are; and I fancy the new growth would ripen well there.—J. A. J., Croydon.

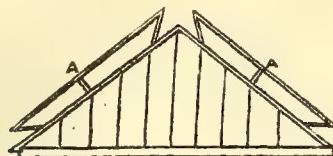

Fig. 1 shows the east end, one sash on the south side, and one on the north side, being tilted. A A are two chocks, which tilt the sashes. The sashes are hinged on the other side.

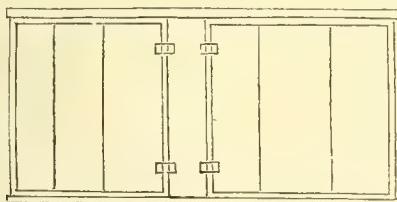

Fig. 2.—South side of span. The sashes, lifting on hinges, give ventilation at top, bottom, and ends.

[We think your plan of ventilation is simple as well as ingenious, and have no doubt it answers perfectly. If you can spare the room, the Camellias and Azaleas will do better there than under the north side of a wall exposed. We would syringe chiefly night and morning. If you do so during the day the ends of common glass should be shaded whilst the sun is full on them. We have no doubt your plants will flourish admirably and be more healthy than when turned out of doors. Many of us are obliged to do so because the place will not hold them in summer and flowering plants too. Give plenty of air, less moisture, and less shading as autumn approaches. There will be something on the subject in *Doings of the Week* before long.]

PROPAGATION OF THE GOOSEBERRY SAWFLY.

In June last I fed up a number of Gooseberry caterpillars till they passed down into the earth to enter the chrysalis state. As soon as they had spun their cocoons I brought them up and laid them out under glass on a sheet of paper.

The first fly emerged on July 7th, and within a few hours of its birth deposited sixty-eight eggs. These eggs were developed into live larvae on July 12th. Now that a solitary fly—excluded from all others from the moment of birth—should lay eggs from which proceed perfect caterpillars is indeed a mystery; and I should like to know whether the law of parthenogenesis prevails here.—E. S.

CULTURE OF THE SOIL OF PERU.

This is the main, and morally, far the most salutary source of the future wealth of Peru, although as yet it has yielded very small results.

We say nothing in this brief sketch of the high table lands between the eastern and western ranges of the Andes—a space of about one hundred miles in width, and from three to fourteen thousand feet above the ocean level. Some of it is very fertile. But we pass to that Eden of the world, called *Montana*, lying east of the Andes and rolling away in an inclined plain of hills and slopes to the great prairies beyond the Ucayali river. This name *Montana* in Spanish does not mean a mountainous, but a wooded or bushy country—a

country covered with clumps of trees or bushes. It is a rolling, farming, feasible, most fertile region, about one hundred miles wide, and the Peruvian portion of it about six hundred long, bounded on the west by the Andes, and on the east by the vast plains beyond the Ucayali, which stretch away to the Brazilian mountains. Of the exuberant fertility of this region I quote three authorities:—

1. Señor Raimondi, a Peruvian of education, who has made extensive explorations under the Peruvian government. He says:—"No words can give an idea of the immense variety of natural productions, and of the incessant activity of Nature in unfolding her creations. In truth, throughout this region are united all the conditions most favourable for vegetable life; such as an atmosphere constantly charged with moisture, a temperature sufficiently elevated, and a rich virgin soil. In every direction there is presented to the eye an exuberance of life so great, that every material object seems to be animated."

2. Dr. Lyman thus sums up its fruits: "Nearly all the tropical productions of the globe are found there. Chief among them are Cotton, Coffee, Sugar-cane, Rice, Tobacco, Cocoa (the Chocolate tree), Indigo, with corn (Barley and Wheat), on the uplands." It should be added, all the fruit of temperate climates can be raised on the highlands. "The forests abound in the various dye-woods of commerce; in ebony and many other kinds of wood valuable for cabinet work, the veneers from which present many beautiful combinations and contrasts of colours. Trees and shrubs possessing medicinal and other desirable virtues, such as Peruvian bark, various balsams, Sarsaparilla, Vanilla, India-rubber, Gum copal, and many others are thrown together in the wildest profusion. . . . Cotton grows wild, and is both white and yellow, the latter resembling the Chinese variety, called "Nankeen." The staple is finer than our ordinary production, and second only to the "Sea Island." There is a species known as "hill cotton," the product of a large tree, that bears it in great abundance. This is also of two colours, yellow, and white as snow. It has the softness and gloss of silk. Another production called by the natives "vegetable wool," is yielded in large quantities by a variety of *Cactus*. It is somewhat like the yellow cotton, but slightly crispy. Several heavy bales of this were recently noticed by the writer on board the steamer from Lima to England, to be experimented on by the cloth manufacturers. The Coffee tree is indigenous in the *Montana*. When cultivated it bears in three years, and each plant is calculated to produce a crop of at least a bushel of berries. Its quality and aroma are equal to those of the finest Mocha. The Sugar-cane, once set, lasts for a generation. Within six months from the planting, the canes are ready to cut. They are large and more juicy than ours, and each plant yields from sixteen to twenty fully matured stalks. Corn and rice mature in four months, and on the ingathering of the crop the ground is ready for another planting, bearing three crops a-year. "In fact," says a Peruvian officer, long resident in Huanuco, "the fertility of the soil is so great that it is only necessary to burn off the weeds and brush in any place, and then to scratch in the seed, to receive in due time a most abundant harvest." The quality of the tobacco is said to be equal to the best of Cuba.

For the common people of tropical America, farina and Bananas are the main reliance for food, and are as important to them as rice to the natives of India. The Banana is everywhere abundant. "The clusters are of monstrous size,"—in one instance "weighing 159 lbs." The farina, made of different species of the *Manihot*, is as valuable to the native as the Potato to the Irish, and, in yield, far more abundant." Grapes are abundant, and the Peruvian vintage will yet, doubtless, be very important to commerce. There are also, native to this region, Oranges, Citrons, Nectarines, Avocada Pears, Pomegranates, the refreshing *Grenadilla*, which is the fruit of the Passion-flower, the *Cherimoyer*, which not unfrequently here weighs 15 or 20 lbs., while in other countries it rarely exceeds 4 lbs.; and a bush called "huaco," a decoction of the leaves of which is said to be a remedy for acute rheumatism and an antidote to the poison of the most venomous reptiles.

3. Thaddeus Hainke observes: "Of the Indigo there is no end. I can say the same of Cotton and Rice. The precious balsam of copaiva, the Sarsaparilla, the Gum-elastic,

and the most fragrant species of *Vanilla* are all produced in an extraordinary abundance in these regions. The mighty forests, like the shores of the rivers, abound in the finest timber for all uses, especially for ship-building, and in trees distilling the most aromatic and medicinal Gums. There is a species of *Cinnamon*, which only differs in the thickness of the bark and its darker colour from that found in the East Indies, and which is as fragrant as the Clove.—(*Christian World.*)

ENTOMOLOGICAL SOCIETY'S MEETING.

THE July meeting of the Entomological Society, in the absence of the President, was presided over by A. R. Wallace, Esq., Vice-President. The meeting was almost entirely occupied with discussions relative to the economy of the hive Bee and common Wasps.

Mr. Tegetmeier exhibited a frame taken from a bar-hive unoccupied by Bees, in which was a quantity of old honey-comb which had been cleaned out by the Bees of an adjacent hive, which had also carefully secured it from falling by attaching a quantity of new wax along the upper edge and sides. This took place about the middle of the month of May, which it will be remembered was very hot and well adapted for bringing out fully the economy of the hive. Mr. Tegetmeier was of opinion that this cleaning and carefully supporting the comb in an empty hive was preliminary to a swarm from the adjacent hive taking possession in a few days of the empty one, thus leading to the idea that it was the swarms of workers (which had already made choice of a new domicile), which led the queen, whilst in the act of swarming, to the spot already fixed upon, and not, as was generally supposed, that the queen fixed upon and led the swarm to a new spot. The cold weather which set in within a few days afterwards, put a stop to all swarming at the time, and the hive consequently continued empty. The fact, well known to bee-keepers, that Bees in swarming will by preference resort to a hive in which comb is already fixed, confirms Mr. Tegetmeier's observations to a certain extent, and it is even popularly considered to be a felony to place such a hive in the vicinity of a neighbouring bee-keeper's bee-house at the time of swarming. Mr. Tegetmeier also exhibited a number of specimens of comb of the Honey Bee, showing some singular abnormal variations in the form of the cells. He observed that the cell of the hive Bee was invariably commenced as a hemispherical cup, and that a section of a cell which was not in immediate contact with other cells was always circular; that the hexagonal form was not the result of instinct on the part of the Bee, but was simply necessitated by a cell being surrounded by six other cells of equal size with it, the enlargement of the central cells being carried to its fullest extent until each of the six sides assumed a flattened form.

Mr. F. Smith objected again, as he had already done on several previous occasions, to this view of the subject, contending that the hexagonal form was the result of instinct on the part of the Bee, and that the theory was opposed by the fact, that the base of the truly hexagonal cells of the common Wasp was flat. Mr. Smith also read a communication from Mr. S. Stone, explaining the manner by which he had induced a small colony of *Vespa germanica*, in the months of August and September last, to construct the remarkable series of nests exhibited by him at the preceding meeting of the Society. The Wasps were placed in a box with an aperture for ingress and egress, and pieces of wire with bits of guide-comb were fixed in various directions to which the Wasps attached their structures in different fantastical forms, being driven from the box as soon as the cells were made, and before any eggs were deposited, into another box in which they repeated their operations.

Mr. Stainton exhibited a new British Microlepidopterous insect belonging the genus *Gelechia* allied to *G. nigricostella*, for which he proposed the specific name of *Gelechia Lathyri*, the species having been reared from larvæ found feeding upon *Lathyrus pratensis*, by Mr. Brown, of Cambridge.

Professor Westwood stated that he had succeeded in rearing *Pyralis farinalis* from the larvæ found in vast profusion in a bin of bran, by Captain Cox.

A paper by Mr. Rowland Trimen containing descriptions

of fifteen new species of Butterflies, from South Africa, was read.

The first Number of a new volume of the Society's "Transactions" was announced as just published, containing Major Parry's monograph on the family Lucanidae, with twelve plates. Amongst the donations to the library received since the last meeting were the publications of the Royal and Linnean Societies, the Society of Arts, the Royal Academy of Munich, the Entomological Societies of Russia and Stettin, the "Journal of Entomology," the "Entomologist," the "Entomologist's Monthly Magazine," Mr. Wollaston's elaborate volume on the Coleoptera of the Canary Islands, the beautiful work on exotic Lepidoptera, by Mr. Hewitson, and a remarkable Memoir on Bat-parasites of the group Nycteribia, treated as a distinct family, by Dr. Kolenati.

WORK FOR THE WEEK.

KITCHEN GARDEN.

AN unquestionable advantage attends the practice of constantly keeping the surface of the ground loose and open about the growing crops, and this recommendation is more particularly applicable to stiff loamy garden lands. From inattention to this apparently simple matter, it is evident that both the absorption and evaporation of moisture must be impeded, and thus the advantage of atmospheric influence considerably diminished. The fork at this moment, for the purpose above mentioned, and the complete extirpation of weeds, should be constantly employed. The decline of some of the earlier quarters of Peas, Cauliflowers, Beans, and Spinach will afford the opportunity of making further additions to the stock of Broccoli, or of planting a main crop of Coleworts. *Broccoli*, if there is any spare ground, plant-out the latest-sown Miller's Dwarf Russian. The Broccoli intended to stand through the winter should never be planted too thickly, as it is then apt to be more tender than when there is a good circulation of air amongst the plants, which makes them robust and hardy. Move the earth well amongst the growing crops of Broccoli and winter stuff, and if the earth must be laid against the stems let it be done right and left with a fork, keeping the work before you to avoid treading on the surface. *Cabbages*, there should be no delay in getting in the main sowings for spring supply. Bailey's Improved is an excellent variety, to which may be added the Nonpareil, Vanack, East Ham, and the London Market. The first sowings may be pricked out into nursery-beds; it is always better to do so in preference to leaving them in the seed-beds, as it makes them stocky and well rooted, and, consequently, better able to withstand the winter. *Celery*, see that it has the surface soil well stirred about it, and give copious applications of liquid manure, with a small portion of salt dissolved in it. *Peas*, the rows that have had crops planted between them must now be entirely removed, and the ground well forked-up. Get ready a piece of ground for winter Spinach, also for winter Onions, and Bath Cos Lettuce. It should be remembered that the present is the most important period of the year for completing arrangements for the due supply of vegetables throughout the winter and spring.

FRUIT GARDEN.

Keep the shoots of Apricots, Plums, &c., closely nailed to the wall, and afford the fruit as fair an opportunity of exposure as possible. Trap earwigs and ants about Apricot trees. See to the speedy formation of Strawberry-beds. Examine the ligatures of stocks budded in July. Budding may still be performed.

FLOWEE GARDEN.

Go over the flower-beds frequently, and remedy any defect that may be perceptible without loss of time; for the bedding-out plants are enjoyed but for a comparatively short season, and now that they are in beauty every means should be used to render them as effective as possible by maintaining the most perfect order and neatness. Where the stock is clean and growing vigorously this will involve considerable labour, and it will be necessary to go over the beds frequently, pegging down where necessary, and cutting back such of the shoots as may incline to encroach on the edgings of the beds. Take advantage of leisure hours to put in cut-

tings, and use every possible dispatch with this work until there is a good stock in a fair way for rooting of such things as are known to be difficult to winter, except in the shape of well-established plants. The earlier kinds of Roses, done flowering, should have all their decaying blossoms removed. Budding this fine family should now be expedited. Where the bark rises badly some manure water should be applied previously, this will cause the sap to flow more readily. Now that the effect of the present arrangement of the colours in the beds can be fairly seen, there is an excellent opportunity for noticing any mistakes, and determining upon the arrangement for next season, and this should be done without delay. Take care that Carnations and Picotees do not suffer from drought. Layering may be commenced with those shoots sufficiently long. Plant-out Pink pipings. Give Dahlias and Hollyhocks abundance of water; tie-out the branches and disbud the former where required, and shorten the flowering stems of the latter. Collect annual seeds.

GREENHOUSE AND CONSERVATORY.

Now that there is a profusion of flowers out of doors, it will not be possible to maintain the interest of the conservatory except by keeping it furnished with handsome specimens of showy plants in first-rate condition. Nothing, therefore, should be brought here at present that is not a fair specimen, and well bloomed, nor should a single plant be allowed to remain a day after it begins to get shabby. It is not desirable to crowd the house with flowering plants, but the aim should rather be to have a moderate number of handsome specimens effectively arranged, which, while flowers are so plentiful out of doors, will be vastly more interesting and pleasing than a large amount of floral display from plants of no individual interest or merit. Remove the flowers of Aphelexis and Helichrysums, cutting the flower-stems close to the old wood, and after cleaning the plants, set them in a cool, shady place when they begin to grow. Such as require it may be repotted. Kalosanthes, the flowers of which are getting shabby, should be cut in. Do not spare the knife on the blooming shoots, but cut them well in below the blooming branches of next year, and where necessary remove two or three tiers of leaves at the top of each branch. Repot such plants as require it, using a tolerably rich, porous soil. Attention must now be paid to late-growing plants in borders, for while in active growth they require a good deal of water. See that large specimens of Camellias are not allowed to get too dry at the root after they have set their buds, for shedding the latter is often due to this cause. Cinerarias for early flowering should now be growing freely, and should be shifted when necessary, for if they are to form large specimens for flowering in winter, they must not be permitted to sustain any check.

STOVE.

Such of the inmates here as are intended for the decoration of the conservatory in autumn and early winter, should be carefully looked over, shifting those which are likely to want more pot room, so as to get the pots well filled with roots before their flowering season. Also, keep the shoots tied out rather thinly, and expose the plants to as much sunshine as they will bear without their foliage being scorched. Those Ixoras which have done blooming must be cut boldly in and started gently to make a new growth. Complete as far as possible the shifting or replacing of Orchids. The Cypripediums and the old Phaius should now be induced to complete their growth, by proper assistance, especially those required to bloom in the dead of winter. The young reserve stock for filling blanks in the stove should be encouraged by progressive potting, and a warm equable temperature. Gesnera zebra, Plumbago rosea, and Torenia asiatica, will amply repay attention bestowed on their culture. Decayed leaves, with a mixture of sharp sand, form a compost peculiarly suitable for the first-named plant.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

THE rain of July 17th, mentioned in our last, was soon evaporated. Many an anxious eye has been directed to the

atmosphere; and the shifting of the wind and the movements of the barometer have been carefully watched. We have dug down lots of Strawberries that fruited early, and made ground occupied by early Peas ready for winter stuff, and never saw the soil so dry before. It is vain to think of planting until rain come, as now we have not a drop of water to give. We have just a little left for plants and fruit trees in pots. The water-question has been a serious one with us for these two summers and makes pot culture a difficult matter. Without our sewage from the mansion we could not have got along this year. As yet we have managed pretty well, and if we only had a nice rain we should do pretty well, for the nights becoming cooler after August, we obtain a plentiful deposition of dew.

What we said last week about choosing the site of a garden, ought to have equal or still greater weight as to the position of new cottages for working men as regards water supply. It is sad to see the scanty wages of labourers broken in upon by purchasing water at a halfpenny or a penny the pail. It is still sadder to see a woman skimming with a saucer the surface of an almost dried-up putrid pool, and then when that settles an hour pouring off the surface again either to drink or make her favourite cup of tea. No wonder that wens and thick necks prevail in some districts. Many of those privileged with abundance of clean water little think of the obligations they owe to the benevolent landlords who make water the primary consideration when building a block of cottages. We could name many hamlets and villages the inhabitants of which either have no well or tank, or no right to go to one which is private property. The ditch and the pool formed by rains that previously wash the highway are almost the only supply, and when these fail the water-cart man must supply them from a distance at so much a-pail. Need we wonder that the want of physical cleanliness in such circumstances is too often associated with moral impurity?

We could do little but lessen evaporation by keeping the hoe going, moving the surface among all growing crops, and mulching those farther advanced. We have shaded Celery with branches until we are able to water it. But for this we should have expected our earliest to have bolted.

FRUIT GARDEN.

The chief features have been getting every little drop of water we could to give a help to swelling fruit. Figs and Peaches especially require it. We should have liked to have syringed the latter more, but our water is scarcely clean enough, what little is left of it. We have potted a good portion of our Strawberries for forcing, and in the manner detailed last season. Melons we have shaded a little, especially when nearly ripe, and it lessened the necessity for watering in the case of those growing freely; otherwise we like to dispense with all shading, except just in sudden extremes from very dull to very bright. This is a matter of more consequence than is generally imagined. Some people shade when the sun is powerful, but the shading remains on when the day has become cloudy, instead of being at once removed. For all fruit when flavour is an object, sun is of primary importance. It is even more essential than abundance of air. Air-giving early does away with the necessity for opening a house all over. Where heat also is required there can be no question as to the economy of making the sun do as much of the heating as possible. We have had and have heavy crops of fine-flavoured Grapes, and the only air given to them has been by small openings near the top of the back wall. Not a front sash has yet been opened. In some of the hottest days a little water was sprinkled on the floors and stages just to prevent overdrying. The air at the back has not been wholly taken away for some two months past. The house, therefore, heats gradually, and any moist vapour has room enough to escape. Whenever Grapes are dewed naturally in a viney, it will be in a morning, and owing to air being given too late. It is not likely we will give any front air until autumn, when we want to keep the Grapes cool after they are ripe.

We have also for some time given air back and front to a Fig-house, as the fruit when fully ripe, as it should be when sent to table from a private establishment, is apt to get mouldy in a confined atmosphere. Here, just now, we are obliged to make a compromise. This body of air and cool-

ness is just the thing for all that remains of the first crop, and especially after a watering at the roots, whilst a higher temperature and a closer atmosphere would be better for the second crop now growing and swelling, and without this much of this crop will not ripen soon enough to be distinguished for flavour. Figs in general have little flavour after the middle of October. In a bright November we have had them very tolerable, and sometimes we have had Strawberries good in that month from late pots, but in dark weather they were not worth eating.

Here we must note, though scarcely in the right place, that the *gum* in *Cucumbers* appeared in three lights in a pit. We cleaned the few plants that were affected, and washed them with clear sulphur water, and soot water, and will see what they will do. We might have pulled them out, as we have plenty of others coming on, and looking all right. The three lights had produced in great abundance fine long fruit of the Volunteer kind; but we have not been able to get a chubby-pointed one, and therefore have not one seed. We would not save from the three lights now, even if the disease appeared no more. This small bed has done quite enough of work; and perhaps it would have been as well to have pulled up the plants, cleared the pit, given fresh soil, and planted again; but if we only could cure this evil we might also be able to prevent it. As yet we know of no remedy when it appears, except fresh soil and frequent planting. In the days of old we once had a fine Cucumber plant, in a large pot, some three years of age; but for some time past we rarely get one set of plants to last out the season, from spring to autumn. We are gratified that so many expressed their approval of what was previously advanced on this subject. After much consideration, we could not but candidly own that we were ignorant alike of the cause or the cure of the evil.

We think we have mislaid an inquiry about Fig trees showing young fruit now in an orchard-house—"Whether they would be ripened in such a place in the autumn: and, if not, whether it would not be best at once to remove them?" They will not ripen unless the airy house is kept closer and warmer, by sun heat, if nothing else. That is a general answer. If September and October be bright, they will have a good chance to ripen pretty well. We would advise, at least, giving them the opportunity, and then you will lose nothing. If at last you see they will do no good, cut off all the fruit, within the sixteenth of an inch of the stem. It would be no use leaving them over the winter, unless you gave the plants heat enough to keep the leaves green. Even then you would not gain much, as your first crop of next season would be poor. Figs larger than a Marrowfat Pea rarely pass the winter well in a cool house, or out of doors. We prefer resting the trees in winter, by coolness and comparative dryness at the roots, and then starting them afresh. Then, from the time of breaking bud and showing fruit, the roots should never be dry, and never in stagnant water. Attend to these conditions, and give little soil to the roots to feed in, and it matters little about pinching, stopping, pruning, tying, or training; the plants cannot help being fruitful, if at all free-fruited kinds.

ORNAMENTAL DEPARTMENT.

Much the same as last week as to regulating, potting, and watering stove and greenhouse plants; but the chief work has been dressing the flower-beds, not only to cause the plants to look their best, but to make them fully cover the beds, so as not to let the sun's rays to the soil. Our principal beds have been well filled since the first week in July—those of *Calceolarias* especially so, and they generally do very well here. We have had to watch them narrowly to prevent them dying from drought, and though we administered a little drop of water to a sinking plant we have had to replace several dozens out of our small reserve. Without rain splendid beds and rows must go, as we cannot treat them much longer even homeopathically with water, and can scarcely do anything more in the way of mulching, as the tops are too thick to admit of its getting down to the bottom of the stems, and too much of it would injure them if much wet came. Last season rain fell when we were in a similar fix, and the *Calceolarias* kept fine until destroyed by frost. The dread of the chief attractions in the garden being destroyed by drought becomes a source of worry, however, and

we should almost feel disposed to employ more *Geraniums* with variegated foliage and fine blooms. When once established the fiercest sun does little to injure them if they have a depth of soil to root in. Even after all the drought we have removed some of the larger leaves to give more light and air to the flower-trusses. We have some rows of *Stella* now magnificent, with their huge corymbs of bloom. We have seen none of the new kinds, even of our old friend Mr. Beaton's, to equal this *Stella* of his, which, strange to say, he himself hardly thought second-rate.

We are glad that the propagation of *Geraniums* is now receiving attention, as we always make cuttings late, because we wish our beds to be at their very best all through the autumn, and even then our cuttings must be small, as we generally give each about one square inch to itself, and it gets no more until spring. As far as we recollect, these fine plants of *Stella* were taken as cuttings in September. Now, however, is a better time every way.

We forgot to mention that about ten days ago, we put a string of *Cerastium tomentosum* round our main ribbon-border. It is straight, and planted in straight rows, thus—back row, *Trentham Rose Geranium*; 2, *Chinese White Daisy*; 3, *Perilla nankinensis*; 4, *Calceolaria amplexicaulis*; 5, *Stella Geranium*; 6, *Prince of Orange Calceolaria*; 7, dwarf blue *Ageratum*, a great acquisition, especially from cuttings; 8, *Brilliant Geranium*; then grass verge and gravel. *Brilliant* is well enough, but the jutting in and out of the foliage did not chime in exactly with the straight line, of the verge and walk. The line, thickly planted with small plants of *Cerastium* about 3 inches from the verge, just supplies the deficiency.—R. F.

COVENT GARDEN MARKET.—JULY 30.

The supply continues good, and so is the demand for this period of the season. Pines, Grapes, Peaches, Nectarines, and Gooseberries, are plentiful. Strawberries are now nearly over. Importations from abroad are kept up, and now include Filberts, which bring from 9d. to 1s. per pound. Of Jargonelle Pears from the continent and Channel Islands there is also a good supply. They may be had at from 1s. 6d. to 4s. per half sieve. West Indian Pine Apples are abundant, and very cheap; Currents of all kinds are plentiful, and, from the dry weather, in excellent condition for preserving.

TRADE CATALOGUES RECEIVED.

John Foulds, Hullard Hall, Stretford New Road, Manchester.—Catalogue of *Chrysanthemums*, *Dahlias*, *Geraniums*, &c.

William Dillistone, Munro Nursery, Sible Hedingham, Essex.—Catalogue of Choice New Plants of 1864.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

MELONS CRACKING (C.P.).—If we read your letter aright, we can readily explain why your Melons crack. There is a word in your letter which may either be mat or heat at night, and whichever it is the atmosphere of the place in which the Melons are growing will be affected. Heat should be applied during the day; and if given at all at night much less will be required than during the day, and a little air should be left on at night. There should be at least 10° difference in cloudy weather, and 15° to 25° in sunny, between the day and night temperatures. If you cover the lights with mats, that will also create a confined moist atmosphere and too high a temperature by night, and cracking will be the consequence. Leave a little air on at night, fire briskly in the day, giving at the same time abundance of air, and keep the fire low by night, or allow it to go out if the thermometer does not sink below 65°. You ought to have given water more copiously at an earlier stage, and not allowed the plants to be without it for weeks.

STRAWBERRY BEDS (W.W.).—Your soil will not do for Mushrooms. They grow best in moderately light rich turf loam. The best time to make Strawberry beds is as early in August as the runners can be had for planting, or in March. As your old beds bloom and set well, we think you will do wrong if you shift the plants, especially as they will never do much good afterwards. Old plants are only fit for the rubbish heap. We advise you to manure well in autumn, and to point it neatly in between the rows with a fork in March. When the Strawberries are in bloom water freely between the rows, give a drenching of water after setting, and mulch between the rows with short grass, or, better still, clean straw. If any difficulty be experienced in watering make holes in the sloping bank, and fill them with water, closing them again after the water has sunk into the ground. If these means be adopted, we expect that your beds will bear well next year. In making new beds dig the ground deeply or rather trench it 2 feet deep, and then work in a good dressing of manure. As your soil is clay it will not require treading, and it ought to give you good crops; but if it were light it should be well trodden down, for Strawberries like a firm moderately rich soil.

THARS ON VINES (A Subscriber).—You have no remedy but to smoke the house with tobacco. Tobacco smoke will not injure the Grapes in the least if the tobacco paper be of good quality; but to make sure, we advise you to employ shag tobacco, and to smoke moderately two nights consecutively, rather than fumigate strongly on one night only. Cucumbers to fruit at Christmas should be sown in the second week in August, the seedlings being duly potted, and planted in their final or fruiting quarters by the middle of September.

ROSES (*Agnes*).—After blooming cut the shoots back to six or eight leaves, and this makes compact heads. Blairii No. 2, Brennus, and Madame Desprez are better adapted for pillars than standards, as their habit is so vigorous. By summer pruning they may be kept within bounds, stopping the shoots to eight eyes, but only once during the summer, and that immediately after blooming, or by the middle of July. Give the Geranium cuttings in pots abundance of water, and the sun shining on the pots will do good instead of harm.

MIMULUS (*Mauchline*).—There are now many varieties much resembling that which you sent in colour and markings, and which did not appear sufficiently striking. Doubtless, however, from the circumstances you name, and long carriage, the beauty of the flower was much deteriorated.

TULIP COMPOST (S.A.M.).—We have found the following the best of all composts for florists' flowers, and Tulips in particular. Take turves from a rich pasture, cut 3 inches thick, lay them in a heap for twelve months, turn them over twice, sprinkling a bushel of soot at each turning to every cart-load, and add one-third sheep manure at the second turning, or, if that cannot be had, hoed, or other well decomposed manure may be substituted. The main point in growing Tulips is to prevent stagnant water lodging in the soil under the bulbs; otherwise, give them what kind of compost or treatment you may, they never bloom satisfactorily. If the loam be heavy a little sand may be added to keep it open; yet Tulips flourish in a rich, deep, and moderately strong loamy soil.

CUCUMBERS DYING (*Idem*).—We think the Cucumbers are not healthy at the roots, and that both the top and bottom heat is too low. Try to encourage vigorous root-action by a little warmth, keep the atmosphere moist, the soil damp, and air on at all favourable occasions. If they have been in bearing some time remove a few inches of the old soil and add fresh, laying in the young shoots, which will root into the new soil and reinvigorate the plants.

PINE APPLE SCALE (An Old Subscriber).—If you had sent a few insects we would have known whether it was the white scale or not. It is difficult to destroy, and if you have only a few plants, the best plan would be, to get rid of them, clean all the place thoroughly, and begin with fresh stock. We have always found the simplest plan was to grow the plants in fresh dung heat, as Pines will bear the fumes from fresh dung which would kill most other plants outright. This will settle those above ground, but will not dispose of those under the soil, hence the difficulty of the cure.

NEGLECTED ORDER (A Gentleman's Gardener in Kent).—There must be some mistake we should think, but we cannot interfere in such matters.

VINES (*An Anxious Inquirer*).—We think you are quite right in not acting upon the advice of those who do not feel themselves responsible for the results. Hear what they have to say, but use your own judgment. Your Vines, pruned seven years on the spur system, will not need the spurs to be brought nearer the rod if they have been properly pruned each year to one or two eyes at the most. They produce good crops of Grapes. What more can you wish for? We advise you to let well alone, and to be content with the Vines as they are, so long as they continue to bear well. We have some now that have spurs over 1 foot long, and though a little unsightly, as you say, some of the Vines are producing upwards of thirty bunches on 26 feet of rafter, and the bunches will weigh between 2 and 3 lbs. each. If you cut the spurs close to the rod shoots will proceed from the dormant eyes situated upon it, and these may show fruit sufficient for a crop, but the chances are two to one that they will not. We do not recommend that practice, but would prefer bringing up a young cane from the bottom, and letting it bear on one-third its length in the following season, cutting off one-third the spurs of the old rod, and so on year after year until the old rod be done away with. By this plan you will improve the appearance of the Vines, but we question whether they will be improved in bearing, though they may if old. For general vineeries we prefer the spur system; but long and short rod also answer well. If there be any difference between one system of pruning and another, the long rod system gives the largest bunches; but what is gained in size of bunch is often lost in flavour, spurs very often giving more compact bunches, more even berries, and better-flavoured fruit.

PAULOWNIA IMPERIALIS (*Laurus*).—It belongs to the natural order Scrophulariaceæ, and is a native of Japan. The common Laurel is *Cerasus laurocerasus*, and the Portugal Laurel *Cerasus lusitanica*.

LAWN SOWING (E.A.P.).—The beginning of April is the best time to sow lawn grass seeds; but you may, if the ground be clean and in good heart, take up the Potatoes, and sow the seeds at once. They will not, however, make much show this year; and unless the land be free from all kinds of perennial weeds, we would not advise you to take up the Potatoes, but let them come to maturity. By deferring the sowing until spring your opportunities of clearing the ground will be greater, and the sward will form all the better in consequence of the soil having been exposed to a winter's frost. If any levelling be required it should be done before the seed is sown. All things considered, we should defer sowing until the spring, though we have no fear of the grasses being injured if sown in August or September. For an acre of medium soil—that is, neither strong nor light, we recommend *Festuca ovina* (Sheep's Fescue), 5 lbs.; *Cynosurus cristatus* (Crested Dog's-tail), 6 lbs.; *Festuca duriuscula* (Hard Fescue), 4 lbs.; *Lolium perenne* tenuis, 18 lbs.; *Poa nemoralis*, 1 lb.; *Poa trivialis*, 1½ lb.; *Poa sempervirens*, 2 lbs.; *Trifolium repens*, 6 lbs.; and *Trifolium minus*, 3 lbs., or 4½ lbs. in all. If the soil is light substitute 1 lb. of *Avena flavescens*, and have 1 lb. less of Crested Dog's-tail; if heavy, add another pound of the last, omitting one pound of *Trifolium minus*. We know of no means of preventing the footstalk coming off in skeletonising, except extra care.

BOOKS (C.M.W.).—We know of no such work. (L.M.N.).—"Window Gardening," which you can have free by post by sending your address and ten postage stamps.

AMMONIACAL LIQUOR (H.).—You may saturate with the gas ammoniacal liquor as you say, the ground from which a crop has just been cleared away, for the purpose of destroying grubs, &c., and if the ground be immediately dug another crop might be inserted safely after the lapse of two days. We should not add house sewage for the purpose. It would be very bad practice to apply the ammoniacal liquor to plants in winter—they are at rest then, and would be injured by such stimulants.

NEW BOILER (A Young Gardener).—If you will send us a drawing we will give you our opinion upon it, and promise neither to publish it nor to pirate it.

FASTOLF RASPBERRY (X.Y.Z.).—Three or four of the ripe fruit and leaves will be sufficient to send, stating the nature of your soil, and whereabouts the garden.

CLAY SOIL (A Constant Reader).—You cannot do better than you propose to give the hungry clay a very heavy dressing of chalk and burnt clay. We should add a large quantity of sea sand. All these additions will tend to improve the soil's staple.

HAUTBOIS.—I beg leave to state that Hautbois means High Wood, and not, as is stated at page 71, Deep Forest, or, in French, *Forêt profond*.—H. KNIGHT, Château de Pontchartrain, Seine et Oise.

[We are obliged for the correction, but we can show authorities for *haut* being translated deep; and whether *bos* is rendered by wood or forest matters little. Accepting "High Wood" as the correct translation, it does not apply to the Strawberry under consideration.]

NAME OF CHERRY (M. Newman).—It is the Reine Hortense.

NAMES OF PLANTS (B.M.).—1, *Spiraea arifolia*; 2, *Erigeron glabellus*. Your Mignonette is most likely suffering from dryness at the root; if not you will probably find that some insect is the cause. (E.C.S.).—Looks like Cheilanthes alabamensis, but the specimen is much too young to enable us to speak with certainty. (G.M.).—*Nepeta nepetella*. (F.S.).—*Oxalis incarnata*. (J.B.).—Tamarix gallica, or French Tamarisk.

THE AGRICULTURAL HALL POULTRY SHOW AND THE POULTRY CLUB.

NOTHING can be more fatal to the success of any undertaking than to raise questions, which, even if satisfactorily answered, may indirectly affect its stability. There is an old proverb about fools and wise men. We know that all persons listen eagerly to inquiries, and are rarely satisfied with the answers those inquiries elicit. This arises from the tendency of human nature to imagine evil, and the difficulty of expressing ourselves so that we may be understood by all.

The proposed show of poultry at the Agricultural Hall, Islington, has, unfortunately, fallen into the difficulty of having questions to answer, and explanations to make. Be they rightly or wrongly put, be they easy or difficult to dispose of, they will have the effect of alarming many. The agitation may be premature, but it has begun, and now there is no alternative but to ventilate the matter entirely, and to give the fullest and most complete answers.

None will doubt for a moment the propriety of the appointment of Mr. Hewitt as a judge. Some question seems to be raised as to the appointment of the other judges. It is hard to say that a judge should not be a breeder or an exhibitor; but it is beyond question that neither directly nor indirectly should a judge exhibit at a show where he is to adjudicate. We must leave the Poultry Club to act according to their judgment, and we must form our opinions by the results.

If the Show in question is to succeed it must be above suspicion, and beyond reproach. Shows will soon cease to be where men feel that they have no confidence, and do not get a fair field. That the Poultry Club in their management of this Show will maintain and enforce that honesty and fairness which is their guiding principle we have no right to doubt.

One cannot help suspecting some hostility to the principle of a poultry club to be lurking in some of the objections brought forward against the Show at the Agricultural Hall. I am inclined to look with favour on the principle. With regard to the existing Poultry Club I cannot say anything, as I do not know anything about it. Amateurs would be glad to know more of it and of its intentions; and most probably that knowledge would conduce to its welfare. A self-constituted and exclusive body cannot be tolerated, yet a poultry club is to be desired.

A poultry club constructed on the limited liability principle, having the proper organisation of directors, officers, and shareholders, might, by common consent, take into its hands the appointment of judges, or, at all events, for all shows that desired to have them so appointed. The Club might also undertake the formation and management of shows in neighbourhoods where they were desired, where a certain sum could be guaranteed, but where there was neither the knowledge nor energy to do the work.

General meetings of the Club should be held at all the principal shows in the kingdom: and it might be expedient to have a northern and a southern committee.

These are propositions which I would do my best to aid, and which I shall be glad to see carried out.—EGOMET.

HAD Mr. Tudman answered my communication himself, instead of delegating the duty to another, it would have been more satisfactory to me, and, I presume, to your general readers also. Why he has not done so is best known to himself. As respects the communication of his *locum tenens*, however, it has not mended the matter, notwithstanding the latter's attempt to raise a new issue on the character of those under whose auspices the doings of the Poultry Club have been ushered into public notice. Now, the "worthy Honorary Secretaries" and other officers may be all that he

contends for; they may be "gentlemen acting and giving their services for the benefit of the poultry-loving community," and be "purely honorary;" they may, as Shakespeare says, be "all, all honourable men;" but when your correspondent urges on the strength of this that "they are not public property to be reprimanded," &c., in other words, that they are above responsibility, I am persuaded I shall not stand alone in demurring to such an assumption. Persons who hold a public position, whether as honorary or paid officers, must submit to public criticism, and to wince under the ordeal is sure to awaken suspicion that all is not sound. Now, it cannot be denied that great soreness has been manifested by both of your correspondents; why, it is, perhaps, not for me to say. One thing, however, which is certain, is, that no assumption nor any amount of soreness can alter facts which are patent to all your readers.

The first of these facts is the correctness of your statement that Mr. Hewitt was appointed one of the judges in the forthcoming Islington Show; and after the evidence you adduced from the correspondence between that gentleman and Mr. Tudman, in which the latter offered, and the former accepted, the office, the genuineness of which has never been questioned, even by Mr. Tudman himself, the bold assertions of Mr. Tudman and his coadjutor "A POULTRY FANCIER" to the contrary can have no other effect, save that of throwing discredit on the other statements of the same parties. It is indeed truly amazing that any one in the face of evidence, such as that furnished by yourself, should have the hardihood to deny so palpable a fact.

The next is, that such offer was accompanied by the withdrawal of the conditions, to establish which, it would seem, is one of the principal objects contemplated in the formation of the Club, and that Mr. Hewitt's acceptance was the consequence, to use his own expression, of such "restrictions being withdrawn." Your correspondent waxes quite indignant at the bare intimation of the rules having been in any way compromised. "How your correspondent [viz., myself] could state that the rules of the Club have been sacrificed or broken down he (the POULTRY FANCIER) cannot conceive; for as yet," he adds, "they have been little acted upon, the test being yet to come." Now, how comes it that they have not been acted on? unless it is that judges of standing and character, like Mr. Hewitt, refuse to act under the restrictions attempted to be imposed by them. If this is not failure, and failure of no ordinary kind, I should like to be informed what is. It is the reference to this fact in your editorial remarks, which, in my opinion, is the gravamen of the offence, and the cause of the soreness felt by your correspondent; and that I, or any one else, should venture to submit that this involves the failure of the elaborate production is, of course, unpardonable in the eyes of so august a body—the more unpardonable on the ground of its truth.

Your correspondent, moreover, offers grave objections to the publication of the names of the judges, for the reason, as he says, that the doing so would afford dishonest exhibitors the means of communicating with them. This is certainly not very flattering to the judges of the Club's selection, implying, as it does, that they are not proof against efforts to tamper with their decisions, notwithstanding the alleged high qualifications of certain members to fill the office: for the judges being above such influences, any attempt would only end in the discomfiture of the exhibitors who resorted to such practices. But since your correspondent has raised this point, it may be asked what security have the public, that exhibitors who are in the secret of such appointment,—for it cannot be supposed that there are no exhibitors among the Honorary Secretaries and other officers of the Club—will not avail themselves of their exclusive knowledge? And if we may judge by the denial of the palpable fact, and other features brought out in this correspondence, the officials are quite as open to the insinuation as the exhibitors.—AN EXHIBITOR.

MALAYS.—The admirers of this variety have now an opportunity of obtaining some of the best strain; for an advertisement states that Mr. C. Ballance intends selling his entire stock. That gentleman purposes discontinuing exhibiting, having so frequently to officiate as judge.

ROOKS.

LAST May I wrote a word or two about these interesting birds; and as Convocation has just been styled in some saucy newspaper "a parliament of rooks," I suppose I must henceforth regard the rook as a brother. I have just returned from a three-weeks visit to the seaside—three somewhat weary weeks to a lover of flowers and birds; for of the former I saw very few, of the latter none, save that I noticed a poor boy with his pet jackdaw on his shoulder, and, in spite of the strong breeze then blowing, the little bird with flapping balancing wings kept his place. I liked that jackdaw, and I liked his fond master—I don't believe he is a bad boy. Three weeks at the seaside, again I say weary weeks. How old one seems to grow, how rapidly old, at a watering place, for how many generations of neighbours one outlives! First when you arrive, there is in the same house the family whom the servants call by their name; they are old inhabitants of a week's duration, while you are only the gentleman in the other drawing-room. How you respect that old family sort of county people of long standing, with their names in the "Dipping Chronicle," among the visitors to that far-famed place. But in a day or two you take their position, and are respected in your turn by the newer comers. Then there are the neighbours outside. That large family in mourning—mourning worth wearing, for a rich aunt is dead, and her money brings them to the sea. Then there is the stout old gentleman with high white straw hat, and long telescope under his arm. Then there are the newly married couples, not that they care for the sea. Happy people, all the world to each other, my blessing upon ye! Now, I know how all these people and many others come to a watering place. They arrive in flys, looking for lodgings. The little girls carry dolls, and poke dolly's face out of the window for her to look at the sea. But I never saw these good people go. They are no more seen—they are missed. Others succeed them at their windows. The large family is followed by two maiden sisters; the stout gentleman by a thin roman-nosed lady; or the lodgings are not let, the blinds are down, and the balcony unoccupied. How did they, how do they go? Not in flys; you never see any save with new comers, though plenty of luggage is carried off on trucks propelled by grim-faced men grinning in the sunshine. Again I say, How do people leave a watering place? Perhaps they leave in the dark to hide their tears.

By the way, there is the reading-room at a watering place. How men congregate there! Poor fellows! they have little else to do. How they browse and browse on morning papers at one time, on evening papers at another; then the weeklies and the locals come in for a pleasant change. And how many generations of readers I outlived in my three weeks! Poor men! they looked so healthy, who would have thought they would have gone off so soon? Just in passing let me say, I did not see on the tables of the reading-room a single copy of "our Journal." Great omission this, for it was just the paper that the browsers would have delighted in.

"But you are saying nothing about rooks, sir." Wait awhile good reader; many a fine mansion has a long approach to it. But for this visit I should never have thought of the rooks, but I missed them, I wanted them, and now at Hilltop I see and hear them once more. I instanced in my little communication of May last the case of two rookeries, one never shot at yet yearly decreasing; the other shot at each year and becoming fuller. Now, I cannot take an old labourer's explanation, "Lor, sir, the birds like it," for I am sure they do not. I regret that I have had no word or hint on the subject in this Journal. However, I have privately had an explanation offered by a sportsman and a naturalist. Would that all sportsmen were naturalists, for then many a poor innocent bird would be spared, the windhover for example. My friend tells me he is sure that cock birds are more numerous than hens amongst most wild birds. Hence it comes to pass that if no rooks are shot, the cocks harass the hens, disturb their sitting, and drive the mated birds elsewhere. This, he tells me, is frequently the case with partridges. The man who to increase his birds allows none to be shot for a season or two, finds presently that he has no game at all to shoot, the quarrelling and fighting

end in dispersion and death. I would also add, Is it not reasonable that the young cock rooks being the stronger, earliest hatched according to your egg-theory, are the first to become branchers? and every one knows that the boldest branchers being clearest from the nest fall most frequently to the rook-shooter's gun.—WILTSIRE RECTOR.

ABOUT PIGEONS AND RABBITS.

ON looking over the columns of one of your recent Numbers, I find a valuable suggestion from Mr. Brent, recommending fanciers of Poultry, Pigeons, Rabbits, &c., to communicate their successes and disappointments, after the fashion of the apiarists. I for one have long wished to see this plan adopted, as I think it would be a fruitful source of instruction and amusement to a great portion of your readers, and be the means of causing many a desponding fancier to be helped out of his difficulties.

I am a Pigeon fancier and have a crotchet that birds breed better if allowed to fly out; consequently, nearly all my breeding stock have been allowed this privilege until now. One morning last week a pair of valuable Turbits took a fancy to try their powers of flight, and very soon lost their "reckoning." Thinking if they could see the other Pigeons they would return, we went into the cote to set them out, and, having gone in rather abruptly, a valuable Carrier cock took fright and bolted. I can assure you that I now felt far from comfortable, but thinking that "of a bad bargain I must make the best," I set two men to watch them until night and then try to catch them; but in this they failed, and the trio remained out all night. The men were on the look-out by three o'clock the following morning, and kept watch all day. During the afternoon the Turbits discovered their home and returned, and by a piece of good management the men caught the Carrier at night. Of course, I had to pay them well for their trouble; and though it was rather an expensive lesson, I consoled myself with the reflection that it might have been worse. All my birds now see the daylight and smell the fresh air through wire-netting.

On looking over my stock after this escapade, I found a Barb hen looking very ill. I put her "in hospital" at once, but she continued to droop and soon died. I opened her stomach and found food, which I feel convinced had been there two or three days. The skin and flesh from the legs towards the tail looked quite green. On opening the ovary I found an egg partially formed, evidently within a day or two of being laid. Can any reader inform me what was the complaint and the remedy?

I am also a Rabbit fancier, but in this a complete novice. I have a lop-eared doe, and I find the hair is coming off her nose and the skin looks rough and scaly like scurvy. I have put flowers of sulphur on the place affected. What is the complaint and the remedy? I have a litter of young Rabbits about two months old, their ears are a tolerable length but both ears fall on one side. I should like to be informed how to make them fall properly. The parents are perfect lops. In conclusion I think I may say with Burns—

"But, mousie, thou art no thy lane,
In proving foresight may be vain:
The best-laid schemes o' mice and men,
Gang after a-gley,
And lea'e us nought but grief and pain,
For promised joy."

—J. I. D.

THE PIGEONS AT THE NEWCASTLE-ON-TYNE EXHIBITION.

BEING an exhibitor of Pigeons at Newcastle-on-Tyne, I went to see the Show, and when I arrived on Wednesday evening I found that two pairs of my birds had never been taken out of the baskets. They left Birmingham on Monday morning, and arrived at the Show between five and six o'clock on Monday evening. I complained to the Secretary, and we looked in the baskets, and found that the birds had not been taken out of the basket and put in the pens. As soon as he saw them he gave the first prize to my Satinettes.

I have been to a great many shows, but I never saw a show where Pigeons were so badly judged as at Newcastle. If I can find out where Mr. T. W. Botcherley, of Darlington,

is going to judge, if I have entered my birds I shall never send them, as I consider that he does not know Pigeons sufficiently to be a judge.—H. YARDLEY.

[This is only one of many strange details we have heard about the Pigeons at the Newcastle Show.]

TRANSFERRING BEES—BEST ASPECT FOR AN APIARY.

I HAVE purchased two hives of bees, swarms of the first week in May, very strong, and of great weight, say 40 to 50 lbs. each. I have not brought them home yet, but intend doing so the first opportunity of getting them in at night. They are now in common straw hives. I wish to know if they can be shifted into a bar-frame hive, or straw bar-hive, without injury to them; but if too late, when can I do so? Can they be deprived of any of their honey if they remain where they are?

Also, my garden runs east to west, somewhat sheltered all round with palings, and currant and other trees. Shall I fix them to face the north? I should state that my house stands at the east end of the garden, so that they would be much sheltered from the east wind.—W. A. P., Oxford.

[Transferring new and heavy combs into frame-hives is far too difficult an operation for a beginner. If you can get some practice this autumn with condemned stocks, so as to master the art of driving bees, you may be able to manage the transfer in the spring. Full directions for performing the operation were given in No. 75 of our new series. Do not attempt to remove your hives until the weather is much colder than at present.

We prefer a south aspect—say from south-east to south-west—sheltered at the back, and from the prevailing winds, and free from all obstruction in front.]

REMOVING BEES TO THE MOORS.

As the time has now arrived for taking the bees to the heather, I would remind your numerous bee-keeping readers of the very great advantage to themselves and the bees which is derived from their removal to the moors. I find that the hives which I keep at home always lose weight after July, whilst those taken to the moors have at least six weeks honey-harvest.

I will now give your readers a few directions for removing the bees. The first thing to be attended to is to give them plenty of room, as, if the weather is favourable, they collect from the heath a very great store of honey; therefore, the day before I remove them, I place another hive on the top of the stock, and if they are in a bar-frame-hive (and no bee-master should use any other description, as in one season the bees will repay all expenses in the extra quantity, quality, and money value of the honey) I take all the honey out, except about 5 lbs., which insures their preservation in case, as last year, it should rain nearly every day they are at the moors. The brood of course must not be cut out of the bar-frames. Over the place where the two hives join I tie a piece of calico securely with two strings round each hive, so that the hives cannot separate, or any bees escape during their removal. I then raise the hive about an inch upon pieces of wood, and early next morning every bee has gone off the floor-board. I then spread a piece of open net or leno upon a board, lift the hives upon the net, and tie it securely with two strings round the hive; and when this has been done, having previously seen which way the combs are built, I turn the hives gently over with the end of the combs at the bottom. With swarms very great care must be used in this part of the operation, as the new combs, being as brittle as glass, will bend and break down with their own weight, and that of the bees upon them, unless they are turned over with the edge of the combs at the bottom. When turned bottom upwards the combs all rest upon their own foundation, and the heat always ascends and so escapes through the net, and the inside of the hive is kept cool. The honey, I find, will not run out of those cells that are not sealed over so as to do the bees any injury.

With old hives the same amount of care is not necessary,

as the bees varnish their combs with a sort of glue; and when they have had brood in them each pupa leaves its silken cocoon in the cell, which so strengthens the combs that in time they become nearly as tough as leather, and you can knock them about as you like, provided you give them plenty of air. The stock, after the above precautions have been taken, may be placed in a wicker basket, or tied in a cloth. Swarms ride the best suspended. The same amount of care in turning them over when you get them to the moors, and in bringing them back must be taken.

These grateful little creatures will repay with usurious interest the expenses of removing them from thirty to fifty miles to such luxuriant pastures, where many tons of honey are annually lost to the nation for want of collectors.—WM. CARR, *Clayton Bridge Apiary, Newton Heath, near Manchester.*

TIMES OF SWARMING.

"PHILISCUS" asks whether a swarm has ever been known to emigrate without a royal cell being sealed, or in process of being sealed. Allow me in reply to express my conviction that swarms generally emigrate before any of the royal cells are sealed.

If you remove the reigning queen from a stock in order to rear an artificial one, you will find that a royal cell is well formed on the third day after removal, that it is sealed on the sixth, and that a young queen emerges on the fourteenth. Hence, allowing two days for confinement of the young queens when formed with a view to natural swarming, this will give for interval between the time a royal cell is sealed and the period of the young queens' emergence, a space of ten, or say eleven days.

Now what are the facts in regard to natural swarming? Take the history of a hive for the following years:—

In 1853	the interval between its first and second was 12 days.
In 1854	" " "
In 1855	" " "
In 1856	" " "
In 1857	" " "
In 1858	" " "
In 1859	" " "
In 1860	" " "

The average interval between first and second casts, according to my experience, is twelve days. Between first and last casts I have frequently witnessed an interval of nineteen days; and in 1861 I had a hive which threw its first and second casts on June 15th and 27th, and its third and fourth casts on July 2nd and 5th, thus making an interval between the first and second casts of twenty days, the longest interval I have ever known. Only on two occasions, once this year, and once in 1854, have I had second casts in less than ten days after the departure of the first swarm. If, therefore, it happens in other localities as in mine, that a second swarm does not depart until ten or fourteen days after the first left, and if young queens are ready to emerge, and do emerge in artificial cases on the eighth day after the royal cells are sealed, it follows that swarms in some instances may perhaps have left before the royal eggs were hatched.—R. S.

EXISTENCE OF A QUEEN DOUBTFUL.

I SHALL be obliged by "A DEVONSHIRE BEE-KEEPER" answering me the following:—I drove a swarm of bees out of an old straw hive about a fortnight ago, they had not swarmed before doing so. I cut the comb out to examine whether the queen had been left behind, but did not find her, and supposed all was right. I left the comb in the old hive for the bees of the apiary to clear out. The following morning I went to remove the comb and old hive, and was much annoyed to find a queen alive, but in a weak state. I had no time to stop and take pains to introduce her to the hive, but placed her inside, when she was ejected immediately. The bees are working well, and I notice that they vibrate their wings opposite to the entrance. Is not this a sign that there is a queen inside? I am in hopes that the queen I found was a young one, that came out of the cell after I had driven them, but I had not time carefully to examine the comb, being called from home. I have a weak east-

ing which I could add to this swarm to make sure, if you think I had better do so. My hives are the wooden octagon hives of Ayrshire, and not bar, so that I suppose I had better sprinkle them well with sugar and water before adding the two together. Your advice will greatly oblige—*LOOSE BOX.*

[If the bees continue to work vigorously there can be little doubt of their possessing a queen. If, on the other hand, they should have ceased active work, whilst other hives remain busy, it may be well to add a small swarm. Sprinkling with sweetened water scented with peppermint will in this case tend to prevent fighting.—A DEVONSHIRE BEE-KEEPER.]

ADDING QUEENS.

I FIND the only safe mode of adding queens is by fumigation. I tried the plan by putting the queen on the top, and when I let the bees in they would soon have killed her had I not taken her away, so at night I fumigated them, and there was no more fighting, and the next day they came off with the queen as a swarm.—A. M.

BEES IN THE SHOW-YARD OF THE ROYAL AGRICULTURAL SOCIETY

AT NEWCASTLE-UPON-TYNE.

THE following extract from the *Northern Daily Express* shows the light in which the unusual sight of an observatory-hive presented itself to the mind of a Newcastle reporter, whose want of knowledge of the subject is evidenced by his mistaking the sex of the working bees:—

"A MODEL FACTORY."

"Stand 194—G. Neighbour & Sons, Regent Street, and High Holborn, London.—We have heard of model farms and model lodging-houses for the working classes; but it was reserved for the Royal Agricultural Society's meeting in 1864 to introduce to our notice a model factory, where we may see representatives of the working classes busily engaged in their daily avocations. The stand which we have quoted above may afford fruitful study to such philanthropists as the Earl of Shaftesbury, who make it their benevolent aim to elevate the masses; and the lesson here given from actual life will not be lost upon working men themselves.

"There are several striking features worthy of notice in the 'model factory.' We can clearly perceive that it has been established on a principle which is essential to the success of any great concern—viz., the principle of a good understanding amongst the operatives themselves, and between them and the head of the establishment. What strikes us in this model factory is the unity of action which reigns throughout. There is no jostling of rival interests, and no misunderstandings or cross purposes. The operatives in this establishment are so numerous that we question if any one has as yet been able to count their number, and yet all seem to be working in perfect harmony, their joint labour continually leading to one beautiful and sublime result.

"Another feature specially noticeable in the establishment in question is the principle of subordination. Singular to say, that while the operatives are males the foreman of this model factory is a female; but that circumstance need not shock the sensibilities of our fair friends any more than it ought to offend the prejudices of the sterner sex, inasmuch as the mighty empire of Great Britain is ruled by the gentle hand of a female; and moreover in the one case as in the other, the presiding genius, amidst all her official cares and duties, takes care to preserve the modesty of her sex. She never in the slightest degree obtrudes herself needlessly on public observation, and probably on that very account the respect shown to her by her subjects is the more profound and devoted.

"There is, however, one particular in which we would take leave to demur to the idea of this factory being in every respect regarded as a 'model.' We have not been able to discover that there is any particular period of the day in which the operatives are allowed to take refreshments. We in England have been accustomed to regard the dinner hour;

somewhat in the light of a sacred institution. And if the Council of the Royal Agricultural Society mean to set this up as a model institution, we are of opinion that some explanation on this point is desirable. Indeed, we have not been able to discover that the operatives in this establishment take any refreshment whatever. If they do, it must be 'on the sly,' vulgarly speaking.

"There is one peculiarity, however, which must tend to popularise this institution, and which has served to make it one of the most attractive objects on the show ground. It is the fashion in all the great factories which abound on the banks of the Tyne, and throughout the country generally, to act on the principle of exclusiveness to a very great extent, and perhaps wisely so. As you approach the door you see an intimation in legible characters 'No admission except on business.' This may be very proper, but it is rather tantalising. In the model factory, which we are now describing, all the operations are open to inspection. Every action is patent to the eye of the spectator. This has been effected by a skilful contrivance, and it is this contrivance, in fact, which has entitled the inventor to obtain a place in the show ground for his model factory, which he describes by the somewhat ambiguous term of 'a new implement.'

"But our readers may wish to learn what is the staple manufacture of this wonderful workshop. We reply—'honey.' The factory we speak of is nothing more nor less than a bee-hive; or, to quote from the catalogue, 'a unicomb observatory bee-hive,' with living Italian alpine bees at full work; invented by T. W. Woodbury, Esq., of Exeter; improved and manufactured by the exhibitors. As implied by its name, this hive has one comb, so that both sides are fully exposed to the light of the day, thus allowing of an easy inspection of the queen bee, surrounded by her retinue. Price £10 10s."

BEES IN SURREY.

I COMMENCED bee-keeping in May, 1863, with a fine swarm. I let them have the whole of their labours of last summer to themselves, knowing that if I took the honey from them I might also take eggs or brood. The result has been, that when your correspondent was describing the danger of foul brood, my stock was hatching-out quantities of young. On the 12th of last May I opened one of my side boxes (collateral-boxes), and on the 26th of July I took off that box and found it contained 25½ lbs. of honey and comb. On the 18th of June I let the bees into the other side box, and that is half full of honey at the present time, besides the middle box or pavilion of Nature, which has all the honey-cells sealed, and with the contents of which I never interfere, so that they have plenty of food to carry them through the winter. At the end of the season I purpose taking off the second box, so that I shall most likely obtain from that stock alone between 40 and 50 lbs. of honey. Whatever it is I will inform you.—T. S.

P.S.—Do you think I shall weaken or impoverish my stock by taking the second box off?

[If the stock-box be well filled, and the side box free from brood, you will not injure the stock by removing the latter.]

SUBSTITUTING BOXES FOR STRAW HIVES.

I HAVE two common straw hives, the one containing a last-year's swarm, and the other an early one (2nd May), of this year; and under each a plain wooden box of my own rough make, both well filled with comb and bees. The end of one of these boxes is glazed, so that I can see that my labourers are rapidly filling it with their gathered sweets; and I have no doubt that the same is the case with the other, as they are a very strong stock, and work well.

I desire to remove the straw hives, keeping the boxes as stock-hives, on which to place supers (of glass) next season. Being a novice, I am in doubt as to the best time to perform this operation. I presume early in September would be a suitable season, but shall feel greatly obliged by your advice on the subject. Probably if the severance were effected now, I should get two stocks for one; but I am indifferent as to that, as I would rather have the stocks in

the boxes as strong as possible, than weaken them by division.—X. L.

[Early in September is a very good time for the operation, which will be successful if the bees have been able to fill the hives with honey and have transferred the seat of breeding to the wooden boxes. You could scarcely have multiplied your stocks in this manner by dividing them earlier in the season.]

EXTRAORDINARY LIGURIAN SWARMS.

On the 7th of June the first swarm came off, on the 11th I heard piping, and on the 16th a second swarm came off. On the 21st a queen came off, and was secured, and made a swarm of; on the 22nd the third swarm came; and on the 5th of July I got a maiden swarm; on the 8th a second maiden swarm; and on the 16th a third maiden swarm, besides which the old hive threw me out thirteen dead queens, and the first swarm has thrown me out nine dead queens, besides the three swarms.—A. M.

BEES DYING FROM CONFINEMENT.

LAST season I bought a capital swarm of bees, housed them in one of Nutt's boxes, and everything went on well until they had filled a bell-glass with honey, and gave indications of throwing off a second swarm ("cast," I suppose). I then added a side box, and the bees directly began to kill each other. After losing some 200 bees I removed the box, and all went on right as before.

This year I took a large bell-glass of honey early in June from the same hive (by the way, why was there a brood-comb in the bell-glass?), and added the same side box as before, partly filled with comb, and they make no progress. They have just begun to kill each other again; and, strange to say, they amuse themselves by dragging dead bees from the bottom to the top of the hive, and then dropping them again. The dead bees are mostly smaller than the living ones.

What am I to do? I want to keep bees as an ornament—they are inside a garden-house—but I have neither ability nor courage to search for the queen, or drive, or artificial swarm, or any other scientific method, of which I read such interesting accounts in your Journal.—NOODLE.

[Your bees do not kill each other, but die from being unable to find their way out of the box. A small entrance in the side box will stop the mischief, by providing a ready means of exit. So, also, with regard to their "amusing themselves" by dragging dead bees to the top of the hive, and then dropping them; this is really an unavailing attempt to clear the hive of dead bodies, and will cease as soon as a direct means of exit is afforded them. The presence of brood in a super is by no means unusual.]

WHAT IS THE DURATION OF LIFE IN THE WORKER BEE?

FROM certain hints thrown out by some aparian writers, I infer they have an impression that an abundance of youthful element in stock-hives in autumn is absolutely requisite to their success in spring. Will Mr. Woodbury oblige me and other readers of THE JOURNAL OF HORTICULTURE, with some information regarding the average length of the natural life of the worker bee? If a swarm were lodged in its habitation on the 1st of May, in what time might it be expected to perish, supposing that at the end of every twenty days, during the summer and autumn, the brood-combs were entirely removed?—R. S.

[I think I cannot do better than quote in reply to my esteemed correspondent, the opinion of that great master in bee science, Dzierzon, on this point. He says the duration of life in the worker bee varies with circumstances. "Of the bees produced in May or June, few live longer than two months, if owing to favourable weather they can be continually busy. If to ever so strong a stock of black bees an Italian queen be given, either in spring or summer, there will after six weeks be but few, and in two months probably

not any black bees remaining. But it also makes a difference how far bees fly, and upon what they pasture. When gathering from the corn-flower for example, they appear to grow old very soon, as the sharp leaves of this flower, as well as the close-growing corn, seem to wear out their wings very rapidly. They appear to preserve them much better when pasturing upon buckwheat blossom, partly because the flight, although strong, lasts but a few hours in the day, partly because they can conveniently hover about the blossom without their wings coming in contact with it. Bees, however, preserve themselves best, and scarcely seem to age at all when in a state of rest. Those, therefore, hatched in September look as juvenile and strong in February and March as if they had left their cells only a few days before. Also, if they pass their time in summer in a similar state of rest, as is the case in stocks without a queen, or inactive from other causes, they may, perhaps, bring their age up to a year, or even beyond it. That the worker bee, even if it escapes every danger, should reach the age of the queen, and live several years, as believed by the Baron Von Ehrenfels, is very unlikely. If he had known the Italian bee, and had experimented with it, he would scarcely have asserted this.]

My own experience, also, leads me to believe the worker bee to be a short-lived creature, whose existence frequently terminates in a few weeks, and is seldom prolonged beyond six or seven months.—A DEVONSHIRE BEE-KEEPER.

FLOWERS FOR BEES.

AT the commencement of this season I procured seeds of borage, poppy, &c., and have noticed that even these, and a large variety of other flowers, have been comparatively forsaken, from the bees preferring what my man calls the "French Willow" [Epilobium angustifolium, Narrow-leaved Willow Herb], amongst which they really seem to luxuriate; and, from their liveliness and buzzing joyfulness, satisfy me that, of all the flowers of the garden, it is the one most palateable. It is, besides, a pretty object at a distance; and, what makes it much more acceptable, it requires no care in its cultivation. I am only afraid, if needed, it would be difficult to eradicate, as the clump which we thought cleared is again as prolific as before, although, out of three yards square, we planted a strip at least a hundred yards in length.—W. G.

OUR LETTER BOX.

SNATH Poultry Show.—I find prizes stated to be given to exhibitors, quite different from what is put down in the catalogue. I find several pens exhibited did not belong to the parties named in the catalogue, yet still getting prizes—not according to the rules, which are very stringent.—COUNTRY SUBSCRIBER AND EXHIBITOR.

WILD FOWL (J. G. F.).—The food of my wild fowl consists of waste bread, the crumbs from the table, and of corn of any description except oats. They are fed on shallow scours, because if the food be thrown into deep water much that sinks is lost. I have always had mine from Baily, in Mount street. Any one is a judge of their condition so far as plumage is concerned, and all there is to guard against is their drowning from dryness of plumage, and their being insufficiently pinioned. The wing should be cut off to the spur.—B.

POINTS OF COCHINS (C.).—A full answer to all your queries would take up too much space. In all Cochins the head should be small and intelligent; the comb small, perfectly straight, and with numerous serrations; the last joint of the wing clipped up, the legs well feathered, the fluff large and soft, the tail small. If the tail be higher than the head, so much the better. Black feathers in the tail do not disqualify. All other distinctions are those of colour only. All mixtures are mistakes.

DORING COCK WHEEZING (Agnes).—The Dorking cock is suffering from cold or incipient roup. In either case the treatment would be the same. Give castor oil freely, a tablespoonful at a dose, and every other day. Twice or three times per day for a week, feed on stale bread steeped in strong ale. Keep him in a dry place, and let him have sun if possible.

SPANISH CHICKEN COMBS (Country Poultry-keeper).—As a rule, we do not choose the largest combs in Spanish chickens, they are apt to fall over, which is a fatal fault. We should prefer the small ones, if the birds are as good in every other respect. At the same time we would not lightly discard the large if they were perfectly straight and upright.

COCHIN HEN DISEASED (H. M.).—We are afraid the hen is a bad case, we have seen many such, and have never succeeded in curing them. The thigh and leg generally wither.

NAME OF BIRD (Pio Non).—From the sketch of the bird which you have sent us, there is no doubt about its being the Pope Grosbeak, which is a species of the Cardinal, but not the crested one.

LIGURIAN BEES (Surrey).—Write to T. Woodbury, Esq., Mount Raiford, Exeter. Bees will not injure poultry, but if too near neighbours the latter will do mischief by picking up tired bees, which frequently drop and rest on the ground near their hives.

WORK ABOUT PARROTS (B. H. W.).—We know of no such publication.

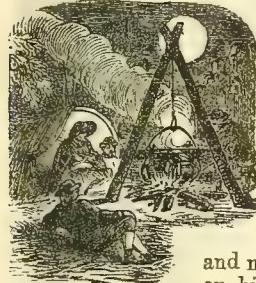

ADVERTISEMENT (Cymo).—We cannot give any opinion on the subject.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 74.2°, and its night temperature 51.0°. The greatest heat was 93° on the 10th, 1842; and the lowest cold, 32°, on the 13th, 1839. The greatest fall of rain was 1.14 inch.

SEVEN YEARS' HISTORY OF A LITTLE LAWN.

RISING young barrister, a very clever fellow, received, one morning, a letter from an old college friend, who had recently become rector of a country parish. The clergyman, after informing his quondam crony that his son, the barrister's godson, aged one year, was getting on nicely, and now trotted about "quite strong on his feet," to use his mamma's descriptive phraseology, proceeded to narrate that finding married housekeeping somewhat expensive, he had determined upon taking pupils. Then came the questions, Would his London friend, who, he knew, saw a great many people in his active career, give him any help should he be able? Might he also refer hesitating parents to his barristership as a referee as to his capacity for teaching, &c.? The barrister smiled at the idea of his very good-tempered but at college rather non-reading friend becoming a tutor, for in truth he had been a trouble to his tutors; though perhaps the London man, being himself very well read, somewhat underrated his friend's knowledge. The two met in the street a few days subsequently, and after such a greeting as only friends in youth give to each other when they meet in after life, the barrister said, "By the way, about your letter. Well, my good fellow, of course I shall be delighted to say a word in your favour, and do all I can for you, pray command me; but I tell you what, Tom," dropping his voice, and with a sly look, "what can you teach?" "Hush!" replied the clergyman, "at any rate I shall know more than the boys." "Well, true; I forgot that, certainly; so you will."

Now, in occupying a little space in the flower department of this Journal, I wish to say I write in a very modest spirit: I am but an amateur, with a heart for flowers and an eye for the beautiful, "still I know more than the boys," and by the boys I mean the young readers of this paper, or the young in gardening experience generally. Now for these I especially write to-day, and for those who have but a small garden.

Seven years ago a family took possession of a prettily-situated house in the country. It was their own; not the Queen and the Parliament combined could deprive them of it. Sense of ownership always brings pleasure; a tenant may be turned out, but not the real owner: hence we usually see, save with the improvident, that it is the owner of a house, or one who rents upon a very long lease, that does much to improve the place, and to make it twice his own by alterations according to his fancy.

Well, the grand moving day came, and the family took possession; the children, in glee, ran from room to room, and the little ones lost themselves in the new house, bolting as often into a wrong room as the right one.

When the house had been put in order, then there was the garden to think about. That denominated the kitchen garden seemed to crave no alteration; but there was the little lawn on the south side of the house—it measured only 75 feet in length, by 55 wide—that must be altered; but how to alter aright was a puzzle. Let us paint the little spot in words. There was the three-foot border under the windows—well, that would do; then the gravel path along that, terrace-like and sunny—that would do; then the lawn, sufficiently sloping to interfere somewhat with a hands-in-the-pocket stroll down, converting the stroll almost into a jolt. On the east side of the lawn was a good border, scimitar-shaped; at the bottom, between the edge of the grass and a well-grown Laurel hedge, was a narrow straight slip—just the thing for standard Roses, as the roots would be kept cool by the shade, and the subsoil was a rather stiff sandy clay. On the west side a dense Laurel hedge severed the garden from the village lane; and in the hedge a noble Elm, fit ornament for any park, but far too large to be near a garden. Added to the mischief of so large a tree (yet, who would be such a Goth as to cut it down?), the lane ran obliquely by, and threw the lawn "all of a squint," as the country people say, making it awkward to lay out, and awkward to plant, as some beds would not come true to the eye. On it the new owner found eighteen beds, chiefly on the top and the side away from the Elm. Little of design was apparent; the beds might almost have belonged to a school of eighteen pupils, each bed being a child's garden, cut out according to his fancy, irrespective of its bearing upon the other beds, or of the general effect.

These were days prior to "King Croquet;" so the poor little lawn was smallpoxed very thickly on three parts of its surface with little ugly beds. The first summer was very dry, and the beds became little dust-holes. (N.B.—They were not dug out to any depth, and the soil of the lawn was made up of the rubbish left when the house was finished: hence it was a concrete of bits of brick and limestone). The first summer, then, was very unsatisfactory. Long before the second came the owner reduced the beds to twelve. This proved a very wet summer, so the little beds were often little ponds, and the flowers bloomed badly. In the third summer the beds were reduced to nine, in the fourth to seven, in the fifth to five, and so they remained for the sixth. Now, upon each reduction there was this advantage gained—the beds being larger, they were less of either dust-heaps or ponds; but there were these two faults—when you reduce your flower garden, by preserving some beds and blotting-out others, it is difficult to make any plan pleasing to the eye; and with this particular lawn, running away to the right "all of a squint," no plan would please—some bed, at some point of sight, came wrong to the eye.

But to continue the story. Last spring every bed was laid down in grass, and an oval one, 22 feet in length, was cut in the centre; it was made 3 feet deep, and filled with good soil. That bed I saw the other day; it was

planted upon the usual system, with an edge of *Cerastium tomentosum*, next *Lobelia*, then *Tom Thumb Geranium*, then yellow *Calceolarias*, with the middle space filled with white, whitish, pinkish, and pink *Geraniums*, while quite in the centre line were dark purple dwarf *Dahlias*, with *Salvias* between. The bed looked nobly; the little lawn was no failure now; while below the bed, on the flatter part of the grass, "King Croquet" was reigning, and a group of happy children, little queens of their several homes, were standing mallet in hand.

Now, what are the lessons to be learnt by the seven years history of this little lawn? First, that in a retentive soil little beds do not answer; while, on the contrary, large beds containing more soil, the flowers in them bloom better. It also says how foolish for little people to ape great people; a simple plan is best for a small garden. Readers, despise not, then, my little history.—WILTSHIRE RECTOR.

VISITS TO GARDENS PUBLIC AND PRIVATE.

MR. BEWLEY'S, ROCKVILLE, DUBLIN.

WHEN, in mentioning my departure to the scenes of my earlier days, I said how difficult it would be to realise the feelings of those days amidst even the places in which they were experienced, I did not sufficiently calculate on the strength of the impressions. I little thought how even the lapse of well nigh thirty years could do but little to efface them, and how every nook and corner came to be as well remembered spots; for I could trace my way in paths which I had not visited since those days; and the faces of those on whom many years had left their sure and certain marks came back to me with all the freshness of those days, and one seemed for a little to be thrown back in one's history, and all that occurred since then to be but an "airy and unsubstantial dream." I do not know whether it falls to the lot of many to have such an experience of life—to be separated for so many years from the scenes of one's youth, and then to visit them in middle life; but I know of nothing that ever preached to me a more solemn sermon as to the lapse of one's own days and the dreamlike character of human life.

However, my work here is not to sermonise, but to give some information on subjects connected with our common pursuit. I have already mentioned a few things connected with what I called gardening under difficulties, but I would not have it to be supposed that this is all that I had seen. I must, however, mention that horticulture did not form the special object of my journey, and indeed so little entered into it, that although I passed through the towns near which two of my correspondents lived in the far north, yet I was unable to visit them, although, as my driver said, one "had the prettiest place in all the county." One show place, however, I did see; and although Mr. Fish has so ably and graphically described it, yet I may be excused, perhaps, saying a few words, for in such a place and under such management as Mr. Bewley's two years make a vast deal of difference. So much energy is shown, money is so liberally spent, and the science of gardening so well understood, that it is remarkable what progress a little time makes.

Mr. Bewley enjoys unusual facilities for obtaining plants, and hence large masses are to be found in his collection which would not be readily found elsewhere. Instead, however, of a long enumeration of the various productions, I may, perhaps, best serve the interests of horticulture if I dwell upon some few points of unusual character which were pointed out to me by the accomplished owner of Rockville. Amongst these was one which was perfectly novel to me, but which may not be so to some of the readers of THE JOURNAL OF HORTICULTURE—I mean the system of double-roofing adopted by Mr. Bewley (Mr. Fish described it two years ago, but it does not seem to have attracted much attention); and to which, indeed, may be added in his conservatory and Orchid-house double sides also. That, however, there is much of novelty connected with it I gathered from the fact that Messrs. Veitch had sent over one of their *employés* to obtain correct information, in order that they might erect a house 130 feet long on this system. We are all aware how difficult a thing ventilation and equable

temperature are in houses, how plants alternate between a dripping atmosphere and a dry torrid-zone sort of state, and how much time, labour, and money are consumed in heating houses. Now, it struck Mr. Bewley that a great deal of this might be obviated by adopting the system to which I allude—that if he could get some 4 or 5 inches of air between the two layers of glass, it would be like Paddy's frieze coat, equally good for keeping out cold and heat, and that, however expensive in the first instance, it would ultimately repay him by the diminished cost of fuel and labour, and this result he has fully accomplished. I am not quite certain as to my figures, although I took them down at the time; but I may safely say that if any further information is required Mr. Bewley would be most happy to supply through your columns any that might be needed. Thus, he has found in his Fern-house, which contains exotic species of various kinds and degrees of tenderness, that he can dispense with the consumption of coke altogether between May and September, and that the amount used from October to April was one-third less than under the old plan. In his Orchid-house he had been exposed to a very severe trial of the plan; for, during the hard frost of January in the present year, he had the unfortunate news brought to him that his pipes were out of order. A man was sent for at once, but some joints had to be fitted which, he was assured, would be ready before night. However, when night came, it was found they were not the size, and he had nothing for it but to brave the frost. We know what that would mean in ordinary circumstances, with the thermometer below freezing at sunset, and no fire (cool-house treatment!)—all would have perished, or been so injured as to be good for nothing. What, then, was Mr. Bewley's surprise and pleasure to find that, owing to his double-roofing, the thermometer had only fallen from 51° to 48°, and as he was compelled to wait another twenty-four hours, that in that time it had only fallen another 3°. He was amply repaid by this one event for all the money he had expended in the double-roofing. Then, again, he is never subject to a dry atmosphere. When he enters the house of a morning the whole upper and under surfaces of the plants are covered with dew; and some of the creeping plants had firmly rooted themselves against the glass. In the fernery the difference of temperature between the bottom and top of the house was 15°; and nothing could be more beautiful than the appearance of this house. I should add that, in the glazing of his house he uses what is called greasy putty—that is, ordinary putty with the addition of a little grease. This never thoroughly hardens, and consequently prevents the glass breaking, by allowing for the expansion and contraction occasioned by changes of temperature.

The fernery is adjacent to the orchard-house, which latter, a fine structure, I was unhappily unable to judge of, as, owing to some circumstance, the trees were not bearing well, and the mildew had largely attacked the Vines. I found, however, that it received at certain seasons some heat, and, consequently, was not the kind of orchard-house that I was most anxious to see, but rather a fruit-house, as indeed Mr. Fish called it; but Mr. Bewley assured me that last year he had had some very fine fruit, and abundantly produced. The fernery is indeed a noble sight, and as the result of but two years growth something remarkable. It would be impossible to give an idea of the extreme beauty of the arrangement and the vigour of the plants which it contains. The gothic appearance of the structure suggests the idea of some ruined church into which has been carried all the choicest varieties of this beautiful tribe. Here were on the floor of the house magnificent specimens of tree Ferns, Cyatheas, Dicksonias, and Alsophilas. Along the sides masses of rocks are arranged of very varied hues—red granite, conglomerate, tufa—of all fantastic forms, and in them were inserted Ferns of the more delicate-foliated kinds, such as Adiantums, &c.; then a staircase, well hidden by rocks and foliage, leads to the roof of the house, where, as the temperature is somewhat higher, the more tropical Ferns are placed; and from this the view over the top of the house is beautiful in the extreme. You have the full expanse of the tree Ferns full in view, one Dicksonia being 20 feet across, while the arches and sides are covered with verdant foliage.

Mr. Bewley had tried various experiments as to what would best contrast with the Ferns. One thing after another

had been tried, and at last a tribe which would hardly have suggested itself to any one, the Begonias, was found to be the most suitable. Those who have only seen these in pots can have but little idea of them as they are grown here. Plants which were placed in crevices with not more than a quart of earth had grown so vigorously that they had run over the rockwork, forming large handsome leaves, and evidently showing that this was their real character—viz., rock plants. Nor is this the only way in which experiments have been tried. The colour of the glass was a matter that gave him some concern, and various tints had been tried; but at last he came to the conclusion that a claret or reddish brown was best suited for throwing up the green foliage within, containing as it did the red, which was the complementary colour to the blue and yellow which in various degrees made up the green of the Ferns and Mosses. It has a curious appearance outside, but unquestionably effected Mr. Bewley's purpose. Not that there was anything of unhealthiness in the Fern-house that required it absolutely, but it only tended to increase and intensify the beautiful freshness within. Amongst other plants used for decorating the sides and roofs were *Ficus stipulata*, *Begonia fuchsoides*, Iviæ of various species, *Hoyas*, *Woodwardia radicans*, *Trichomanes radicans*, &c.—in fact it is a fairy scene, which, as the old story goes, must be seen to be properly admired.

Nor can I omit what I believe is Mr. Bewley's especial pet. He has in his dining-room a large oblong Fern case, containing the most beautifully luxuriant mass of the Killarney Fern that can be possibly imagined. Mr. B. says that the great secret in growing this is not to encumber the case with soil, but to plant amongst pieces of rock, using comparatively but little mould. I can only say that in its way the case was on a par with the very beautiful mass of the Tonbridge Wells Fern which I saw last year at Lady Dorothy Nevill's.

Since Mr. Fish's visit two years ago Mr. Bewley has added another very charming feature to his grounds in a garden for his daughter, who felt that she could not enjoy the garden owing to its fame bringing a constant stream of visitors. This garden may perhaps be best described as a cloister, round two sides of which run a series of gothic arches glazed at top. These arches are made of tufa, and at their base were planted Honeysuckles, Iviæ, Clematis, &c. The borders are planted with flowering Peaches, Rhododendrons, &c.; and this indeed was the only exception I could make to the great taste displayed, as they were too large for the space, and did not agree well with the other arrangements. But what glorious masses of Ferns there were! Wouldn't Mr. Ivery be delighted to see some of his choicest pets flourishing here in such grand vigour? Here was *Athyrium Filix-femina* Frizelliae, there *plumosum*; here, again, a noble plant, *Athyrium Filix-mas* crispum, there *Osmunda regalis* was treated to a place especially prepared for it and two other kindred species. But I question very much whether it is necessary to give this Fern so much moisture as is commonly done. I saw it treated as an ordinary garden plant in the garden of Lord George Hill, and the plants were from 4 to 5 feet high; while on a sod of turf near his lordship's excellent hotel at Gweedore I saw a nice plant of it luxuriantly flourishing on the top of a dry bank. Then the Aspleniums were well represented, and, indeed, the greater number of our British Ferns. As this is only a recent construction it will improve from year to year; but even now it is as beautiful in appearance as it is novel in design. In the lawn enclosed by these cloisters flower-beds were introduced, as well as standard Rhododendrons and Conifers; while at one end a wide-spreading Beech invited any Titurus or Melibeus to repose beneath its umbrageous branches.

It would be impossible to adequately describe the beauties of the conservatories and houses, nor, indeed, do I consider it at all necessary, as it has been done so well and ably by Mr. Fish; but I have thought it well to mark a few things that struck me, in the hope that they may show some of our friends what can be done in poor Ireland. Many people seem to have an idea that in all things she is behind the rest of the world, but I think Mr. Bewley may fairly challenge this country to produce any collection superior to his own; and to one who, like myself, can look back on what horticulture was some thirty years ago in Ireland and con-

sider its condition now, it is indeed very marvellous to see the improvement.

There was one whisper that I heard, however, which grieved me somewhat; and that was that the fatal policy of ignoring florists' flowers, and exalting stove and greenhouse plants and Orchids, is creeping into the councils of the Royal Horticultural Society of Ireland. I may instance as an example, that florists are expected to exhibit Carnations and Picotees on the 1st of September, because the Society could not afford to have the smaller exhibitions at which those flowers used to be exhibited, and this with, I believe, nearly £1000 in hand! Two large growers have given up growing them for exhibition, feeling that it was impossible to fulfil the conditions required; and hence a beautiful and favourite flower will be neglected. As an outsider, only interested in the success of horticulture, I hope that my words may be taken as they are meant—in a friendly spirit, and used for the best interests of the pursuit of horticulture.—D., *Deal*.

HEATING BY STOVES.

In No. 153, page 172, there is an Arnott's stove strongly recommended; but I should doubt the practicability of daily cleaning out the clinkers, &c., as the depth between A and B is so great. Could not the same plan be carried out with an opening at top just in front of the chimney? Would the bent pipe answer as well if made of one-inch gas-pipe and to come out through the cover at top?

In Vol. XXVIII., page 630, is another Arnott's stove without hot-water pipes, and which I think of trying, but "J. S." omits to state the length of flue in his eighteen-feet house. I have always heard that these stoves require to go into a chimney within 3 or 4 feet in order to obtain a good draught. The furnace-cover is said to be 13 inches square; but this must be too small to cover a wall 4½ inches thick back and front, with a ten-inch opening. It should be 19 inches square at least. I am constructing a pit 20 feet long by 7 wide, and 6 high in the centre, sunk 2 feet. Should I place one of these stoves in the centre with a chimney to go out at once? Should a chamber be formed at the west end so as to grow Cucumbers and act as a propagating-pit? What sized pipe would be required for a chamber 2½ feet wide by 1 deep (What depth is best?), and 20 feet long? Perhaps for such a pit the bent pipe passing once through the furnace would not be sufficient.

I have a greenhouse 15 feet by 8½, with a hipped roof, back wall to the east, and on the west side is a tank 4 inches deep, 2 feet wide, and 8 feet long. I have fixed one of Riddell's slow-combustion stoves inside the house. It works well and is easily cleaned out and supplied with fuel at top. The three-quarter-inch pipe is bent to go into the wooden tank. The stove, no doubt, will keep out frost in winter, but on trying the stove and tank for two or three weeks I find the water gets sufficiently warm to heat the sand above the slate covering to the tank in two hours. If I were to make up the fire to last the night I should have the water boiling and at too great a heat. I had a great difficulty in keeping back the steam at the opening where I supplied the tank with water. I placed a large tin box over the opening, dipping into the sand, to keep back the steam. This takes up much room. Would not a two-inch drain-pipe, with a cover fitting into sand, do as well to keep back the steam? I am obliged to take the flue in a 3½-inch iron horizontal pipe, 30 feet across a yard into a chimney. It draws sufficiently well at present. I burn coke and cinders. How can I check the heat in the tank? If the fire is not attended to it is out in two hours. My great trouble in heating this small house was having no flue or chimney to go into. So small an iron chimney would soon have become clogged if coal had been used with the usual furnace and flue.—G. C.

[Your various questions clearly show the importance of making every plan and system stand or fall on its own merits. Many plans and systems fail because those who adopt them must leave out something, or add something of their own devising, and then they are always good enough to blame not their own superior wisdom, but the system which they did not adopt, from attempting to improve it. Now, though we have not tried it, yet in opposition to your doubts, and judging from analogy and experience of other

stoves, we should have no doubt at all of the stove described at page 172 of the last volume answering admirably. There is not a point we would wish to alter. The stove being placed inside the house, a close-fitting doorway is essential, and we can see no advantage in placing that feeding-door higher up opposite the chimney. The reason for the position of the feeding-place we deem most conclusive. An opening in the cover of the stove would taint the house every time it was opened.

What you say of the impracticability of cleaning out the clinkers almost shows you must have skipped the description of the peculiarity of the grating or fire-bars, which, dropping down whenever you wish it, allow of everything being removed at the ash-pit door without any necessity for putting your arm down inside at all. This plan of grating for stoves or boilers was, we believe, first given by Mr. Allen, in a previous volume, and repeated in our manual "Heating," page 37. Be assured no opening at top from such a stove inside the house would suit equally well. Your proposed bent pipe of 1 inch would, no doubt, give you heat in proportion to its size, but the double size of the pipe, and the bend in the fireplace, in the plan, would be likely when wanted to give three times the amount of heat; and if not quite so much, there would be the advantage of never having the pipes so hot as they would be from a one-inch pipe.

Then, again, by turning up the plan referred to in Vol. XXVIII., page 630, you will perceive that you have, no doubt, unwittingly mingled what is quite separate and distinct. What is there given is not an Arnott's stove at all, but merely a distinct form of furnace for a flue; the furnace placed outside, not inside of the house. Hence the moveable lid at top is no disadvantage, which it would be were it inside of the house. The peculiarities of this furnace as compared with those in common use are, first its being fed from the top by a hinged lid, and, secondly, the moveable grating, as described in the case of the stove just spoken of. The height and smallness of the opening into the flue will insure a good draught, as no doubt there is a chimney at the other end. There is no mention of water-pipes, although no doubt they could be introduced if deemed desirable. The fact of the furnace being outside of the house does away with your objection to the size of the covering plate. One of 13 inches square would give $1\frac{1}{2}$ inch all round the opening of 10 inches, which under the circumstances would be sufficient. We should have no objection to the 19 inches you consider necessary, except the greater expense of the plate and the greater weight and trouble in raising it. We advert to these little matters more particularly, as critics and improvers should be correct in their references.

Now, certainly, we would not approve of constructing such a furnace (stove) with a moveable top, in a pit 20 feet long, 7 feet wide, and 6 feet in height at middle over pathway, with or without the hot-water pipes for growing Cucumbers, as there would be danger every time the cover was raised to replenish the fire. If the stove must be inside and fed inside we would prefer the form of stove first referred to, at page 172 of last volume; but so liable are Cucumbers to suffer from the least back draught, that if for economy we wished the heat from the stove to be given to the house, we would construct it inside close to the wall, and have the feeding-door and ashpit-door outside of the house. To get bottom heat either with or without a chamber, the stove must be sunk sufficiently low to let the pipes or flue ascend into it. For such a chamber two two-inch pipes would be necessary for early Cucumbers. The pipes should be near the top. See notice of such chambers at Berkhamstead Nursery in a previous volume.

It is always well to stick to the boat that carries us safely over the river. On this principle we would advise you to keep to the Riddell stove that does such good service. Even with that and its moveable top we would be a little timid as respects Cucumbers. It is very different as regards the low heat required in a greenhouse. We presume your stove has no water round its sides, but that you take the three-quarter-inch pipe from the stove. In such a case the fire must be pretty strong to heat so quickly a tank 8 feet long, 2 feet wide, and 4 inches deep. We know of no remedy against over-heating except stopping the circulation, enlarging the size of the tank, or careful firing. When once the requisite

heat is obtained, it can only be kept regular by a very slow combustion. This is best done by carefully regulating the air through the ashpit-door. This is well adverted to at page 172 of last volume. In fact, that stove by care can be a stove of slow or rapid combustion just as it is desirable. But for your rather lofty chimney we suspect the 30 feet of a flue running horizontally across a yard would have been a difficulty. You are right in supposing that stoves without such an accessory do best with a very short horizontal pipe. Various modes have lately been described for getting rid of steam, vapour, &c. We trust you will now see that the plan for a furnace outside of a house is a different thing from a stove to be placed inside of a house, and that for these distinct purposes the plans would severally be efficient. The authors of these plans will, perhaps, offer further explanations if deemed necessary.—R. F.]

NEW STRAWBERRIES.

On my return from a very pleasant ramble in England, where I saw as usual many beautiful and interesting things in connection with horticulture, I beg to submit to your readers a short account of several new kinds of Strawberries, based upon my own personal experience, and some of which have already been alluded to in this Journal. First on the list stand the following seedlings, raised by that eminent horticulturist, Mr. de Jonghe, and which, as Dr. Hogg, rightly observed to me, "constitute a really new race," inasmuch as the fruit is so solid that it will safely travel almost any distance. This point has certainly long been a great desideratum, and its attainment is a decided step in the right direction, combined as it is with the other necessary requisites of a good dessert Strawberry. Who is the amateur grower that does not now know La Constante, succeeding so well in all parts of England as well as everywhere, and producing rich large crops of the finest fruit imaginable?

As there is, however, "no Rose," or scarcely any, "without a thorn," this splendid sort has one single fault—that is, the scarcity of the runners it produces, and this circumstance must prevent its being grown on a larger scale for market purposes, at least for many years to come. Thanks, however, to the persevering efforts of its raiser, we have now several kinds possessing all the high qualities of La Constante, together with the important improvement that they are growing more freely and may, consequently, be propagated as fast as any. These are:—Souvenir de Kieff, La Fertile, and last, but not least, Léonce de Lambertye. All three are of unquestionable merit, and ought to be not only in every private garden, but also in the field to supply the million.

Then we have Bijou, a most curious sort, and undoubtedly the prettiest and one of the best Strawberries ever raised. This sort, not being a strong grower and but a shy runner, will necessarily be confined to amateurs' gardens, and would be an excellent variety for ladies who take an interest in the useful pastime of growing Strawberries.

Of English novelties I beg to mention the following:—

JOHN POWELL (Royal Gardens, Frogmore).—A great acquisition and an immense bearer, of first-rate quality. I do not, however, consider it "Queen-leaved" nor "Queen-flavoured," as the Rev. Mr. Radclyffe stated in a recent Number. Nevertheless, it is a very useful sort and can be safely recommended to any one. Through the kindness of Mr. Powell, whilst in England I had occasion to taste some other seedlings raised in those magnificent gardens—viz., Fairy Queen, Elton Improved, Cockscomb, and several others, which will in due course be right welcome to all true frugarians.

INGRAM'S RIFLEMAN, such a grand Strawberry in most English soils, does not succeed here, the French climate being evidently too dry, and our sun too powerful for it. On the other hand, Frogmore Late Pine is a favourite here and thrives well.

THE PREMIER is apparently a very useful sort, large and good, and, what is not to be despised, an enormous cropper. I had runners of it late in the autumn through Mr. William Paul, every one of which produced three or four fruitstalks! What a crop may we consequently expect from strong established plants?

PRINCESS OF WALES (Knight's).—The earliest sort I know of, and quite as early as May Queen, but much larger and of exquisite flavour.

I must not conclude without mentioning Sir JOSEPH PAXTON, of which I saw a few berries on calling upon Mr. Turner, who, with his usual politeness, allowed me to taste them. This is another Strawberry worthy of general cultivation, and every amateur ought to be anxious to possess it, and will find it a worthy companion to President, sent out last year by Mr. Turner.—FEERINAND GLOEDE, *Les Sablons (Seine et Marne), France.*

CITY GARDENING IN NEW YORK.

ONE of the most pleasing features in this city is the number and variety of shady trees planted along the side walks of many of the principal streets and avenues, and, being almost entirely deciduous, they form a most grateful shelter from the scorching rays of the sun during the sultry summer months; and never has their shade been more agreeable than during the last week of the past month (June). The thermometer in the shade during that period daily indicated 95° and 97°. One day, the 26th, it ranged up to 102°—an almost unprecedented heat for June; so that when at length the temperature fell to 75° we almost shivered with cold, and had to resume thicker habiliments.

The principal varieties of trees planted are Catalpas, Sycamores, Paulownias, Ailanthus, Hickory, Maples, Locust, Elms, Lindens, Horse-Chestnuts, Willows, Tulip Trees, Buttonballs, deciduous Cypress, &c. Besides doing good public service as shady trees, many of these are highly ornamental. Two weeks ago the Catalpas were one mass of bloom, and, having a broad umbrageous foliage, they would be most pleasing objects for the eye to rest upon anywhere, and are especially so in a crowded city like this. The Paulownias flowered very profusely in May and June, setting very freely; but the Chestnuts do not flower with the same rich profusion that I have seen them do at Hampton Court.

These useful and certainly most inexpensive public servants have most ruthless enemies in several varieties of caterpillars, which attack them in early summer while the leaves are yet tender, and seriously endanger their utility. I have seen many trees of Maples, Lime, Chestnut, and Willow almost entirely denuded of their foliage; and just now these present rather a curious appearance, having again clothed themselves with fresh foliage, in striking contrast to some of their neighbours, which enjoyed perfect immunity from the "flank movements" of the caterpillars. The Ailanthus, Catalpa, and Paulownia are untouched. Of these the graceful Ailanthus is most extensively planted, the only objection to it being the sickly odour emitted from the flowers when in bloom; but this is not the case with the male variety, which is now much sought after. The foliage being of a much lighter tint, it is readily distinguished from the other. The public squares are also well planted with trees and shrubs, and just now the colour of the foliage is most refreshing to look at.

The other evening, taking a stroll in the "gloamin" through Union Square, it was pleasant to behold thousands of the people walking about and sitting under the trees enjoying the fresh breeze in the cool of the evening, the water sparkling in the fountain, and the beauty of the whole scene much enhanced by myriads of brilliant fireflies fitting about, making the gas lamps for the prosaic and unnecessary purpose of lighting the square look like a most decided artificial innovation on nature.

As an instance of the perfection to which city gardening may be carried under many existing difficulties, we have the compact and most judiciously arranged establishment of R. Stewart, Esq., in Fifth Avenue, presided over by his gardener, Mr. Davidson, where just now the grass is as green and close-shaven as any nobleman in England could wish his ancestral lawn to be; and this is the more creditable, as we have had no rain, with the exception of a passing shower, for fully two months. The show of spring bulbs in the flower garden here would have delighted even the noble proprietor of Cliveden. The Hyacinths in particular were gorgeous, not only as a general mass, but also for individual spikes; and in June the Roses were also very fine, but only

too shortlived, the hot weather soon making sad havoc with this favourite flower. A botanist might also light upon some native varieties of plants stowed away in a corner, the pickings of many a botanical ramble of a brother of the present gardener.

This, although perhaps the most striking, is not by any means a solitary instance of successful city gardening; and the taste for such is rapidly developing on this side of the Atlantic, in spite of the many drawbacks at present existing.—DAVID FOULIS, New York.

ORCHARD-HOUSES IN THE NORTH.

I REGEET to find that Mr. Rivers has awakened the ire of our brethren in Yorkshire. Mr. J. Acomb, as the mouth-piece of the offended party, has shown that fine Peaches can be grown near large manufacturing towns. I could name more than fifty places in the heart of the West Riding, where Peaches and Nectarines are grown quite equal to any produced elsewhere, and I have no doubt whatever as to their being much superior to any grown in orchard-houses in much more favourable localities farther south. But their being grown under glass has nothing to do with the question. "Have they been grown in houses of simple construction without artificial heat?" I have given my reply in the negative, and it has only been met by confirmatory evidence. True, we are told that such orchard-houses have succeeded in some places, but questions of import are not settled by isolated cases, but by the majority.

Within a circle of some ten miles in diameter I find twenty-three orchard-houses, and nothing like successful Peach-growing to be seen in any of them, being nineteen in favour of the "ayes." More than this, a nurseryman travelling to and fro in the north writes, "I have seen many of these houses, but never found a crop of Peaches in any of them," adding, "I have no doubt that Peaches can be grown, but the question is not what can be, but what is." So with Peaches at and near Bradford; Peaches are grown successfully in many places in heated houses; and even without such assistance, when protected with a substantial wall, you may see them in almost every garden of note; but we must travel over one hundred miles of country to Liverpool or Nottingham, or, if we like it better, have a two-hundred-mile ride to Herts, to see that which is said to be grown in many places in the north, still nobody knows where, and when we ask where, we are told to go to the places named. We are to go to France to see what will enable us to overcome the difficulty of the situation. We are to shut our eyes to the fact, that our neighbours have abundance of Peaches in houses constructed so as to be suitable for the climate; and whilst we have nothing but a structure totally inadequate for the purpose intended, and knowing what will enable us to overcome the difficulty, we must avail ourselves of the orchard-house without telling those who furnished the "wrong thing," that we are not pleased with it. Very few persons having spent £100 on an orchard-house, and after much annoyance, like to be told that it is unsuited for growing Peaches, and will require an outlay of £50 to make it suitable for their production.

Passing over the lucubrations of "PENDLE" and others, not excepting my other opponent, "WYESIDE," I come to what may be taken as the arbitrary charge of the judge to the jury, or an explanation of some questionable point of law. I allude to the Editors' note appended to my reply to "WYESIDE," at page 8.

The superiority of fruit grown under glass over that on walls, results in their being "nearly" as fine, luscious, and high-flavoured as the best ever grown against a wall. Their inferiority is admitted. Point 1, Fruit ripened naturally is superior to that produced by artificial means, is therefore conceded. Mr. Pearson will be pleased to take notice that his superiority dwindles into nearly equal. There is a great deal of difference between nearly equal, equal, and superior.

The question of light is also conceded. Point 2, Peaches under glass receive less light than those on a south wall. "WYESIDE" will, of course, take cognisance that my palpable error is admitted to be correct.

As to the other points in dispute, which I will term point 3, that orchard-houses for the growth of the Peach

and Nectarine must be heated in the north, has not been met by any evidence whatever to the contrary, and yet we are asked to believe that Peaches are so grown (without heat) in many places. More besides me ask where? The evidence being twenty-three cases of failure in a circle of ten miles, to four of success in the whole north, this point is claimed also.

Point 4, a wall covered with glass is better than an unheated orchard-house, span or lean-to, or is not equal to a wall covered with glass for the production of Peaches or Nectarines. No evidence against this is furnished, but Mr. Pearson strives to make it appear that I advocated the building of walls in preference to erecting orchard-houses. My argument was and is, that Peaches and Nectarines have been grown, and can be now, on walls with equal certainty to those in orchard-houses with wooden sides and ends and a glass roof. As for Apricots, they are grown more abundantly and with greater certainty on cottage walls than in orchard-houses. I do not think it necessary to show why a wall covered with glass should be better suited for protecting a Peach tree in the north than a frail structure of wood and glass. If you build brick walls to your orchard-house instead of wood and otherwise make it such as has been employed for generations for the growth of Peaches under the designation of a Peach-house, and call it an orchard-house because the trees are in pots or planted out, yet trained as standards, bushes, or pyramids, I think you would be better thought of if you were to give things the same name as that by which our forefathers knew them.

I now retire from the controversy; and if anything like wounds are felt, I can only hope that they will soon heal kindly and no pain be given when the sore is touched afterwards. I have done with the subject.—G. ABBEY.

EVIDENCES OF PROGRESS.

WE are told that in a religious periodical recently appeared a dirge, entitled "Pray for Daventry," and we consequently inquired what calamity had befallen the place. The reply was neither clear nor satisfactory, but we waived further inquiry, for we knew that we should ere long be at this Bennavenna of the Britons; and that visit being now passed, we will note down a few facts which lead us to the conclusion that the place is not altogether in a state abandoned—and improvable only by prayer.

Talking over the recent discussion in our pages about "foul brood," and inquiring if it had been noticed in the neighbourhood of Daventry, we were referred to a Mr. Piddington, and in search of that authority we at once set forth. We found in him an example of that higher class of artisan which was so rare fifty years since, that it may be considered as a creation of the last quarter of a century. "The schoolmaster being abroad" among artisans, facility of intercourse with other places by the agencies of the railroad and penny postage, have raised this class from the mighty multitude of English artisans. These artisans have ever been distinguished for acuteness, thirst for information, and mental independance. The agencies we have mentioned placed the acquirement of knowledge within the easy reach of them all; and those of them who had minds most capable of improvement, and who were most sedulous to improve, form that high class of artisan of which Mr. Piddington is so good an example.

We should not be justified in particularising all we noticed, but we may say the neatness and comfort diffused over his home, and the attention to arrangement and harmony of colour in the small flower-beds of the small garden, indicated a well-ordered mind and a cultivated taste—such comfort, and neatness, and beauty, would not have been there if not fully appreciated. We will only particularise of the garden that we never saw anywhere else the edging of the leaves of Geranium Golden Chain so brilliant.

The apiary was in excellent order, and "foul brood" unknown in it, though a greater number of dead larvae have been thrown out this year than is usual. There are about twenty stocks in the old-fashioned straw hive, seven in Marriott's hives, and one in a box-hive of Mr. Piddington's own devising. The old-fashioned hives he will gradually supersede, and he is about changing them all to a southern

aspect, which he finds by far the best—there the bees being stronger, and their honey-harvest the largest. From his seven Marriott's hives he has this season taken more than 100 lbs. of honey in bell-glasses, yet the store for winter in the hives is ample.

Last year we visited the Horticultural Show at this town; and this year we reached it on the day of its annual Gooseberry Show, but too late to see the fruit exhibited.

In the course of our rambles round we reached Norton Hall, the seat of the late Mr. Boutfield, one of the Vice-Presidents of the Linnean Society; and we must record our hope that Mr. Smalley, the intelligent manager and gardener, will be permitted to complete the improvements—the great improvements—which were in progress when Mr. Boutfield died. They are worthy of the family motto, "*Jay bonne cause*," and so is the transformation of the cottages around. They were miserable hovels; but now they are all substantial, comfortable dwellings, looking respectable, and fostering that good preservative from evil—self-respect.

The maternal grandfather of the late proprietor was the celebrated Dr. Withering, author of the "Arrangement of British Plants," and we note this for the purpose of recording that an excellent portrait of him is among the numerous pictures in the Hall. He is seated with a stem of the Foxglove (*Digitalis purpurea*), in his hand, for the use of which in medicine he was an early and efficient advocate.

Many other notes have we of progress in and about the town, but they are of a character not the legitimate themes of our columns, but the instances we have glanced over are sufficient to testify that there is something to be thankful for as well as to pray for at Daventry.—G.

EFFECTS OF SMOKE ON VEGETATION.

DR. VOELCKER lately read a paper on "Smoke and its Effects" before the School of Arts, and the following is a passage from his lecture which especially interests the agricultural reader:—

"Wheat, Barley, Grass, and Clover, exposed to a smoky atmosphere at an early stage of their growth, are visibly affected in a short time. The tops of these plants turn first red, then yellow, and finally white, and an effect is produced not unlike that caused by frost or excessive drought. Corn crops affected in this manner by smoke may recover to a certain extent, but they never yield well, inasmuch as the development of the plants becomes irregular, and the corn ripens unequally. If cereals are attacked by smoke when in flower, the ears do not fill well, and the grain is of a poor quality.

"Grass and Clover, more or less discoloured or bleached and damaged by smoke, are disliked by cattle, and often rejected by them altogether. Smoke deteriorates the quality and diminishes the quantity of Grass and Clover crops. Plants with strongly developed leaves—for instance, Mangolds, Swedes, Turnips, and other green crops—are less liable to suffer injury from a smoky atmosphere.

"Fruit and ornamental trees, on the other hand, are readily affected by such an atmosphere. The leaves turn yellow, brown, and finally black, and then drop. If the leaves are destroyed two or three years in succession, the trees become sickly, and finally die off. Fruit trees in blossom attacked by smoke yield no fruit, or but a poor sickly crop.

"During the combustion of coal much sulphurous acid is generated, which is carried away by the smoke of the fire. The injurious effects of smoke on vegetation are evidently due to sulphurous acid—a gas which, according to experiments made many years ago by Turner and Christison, causes the leaves of plants to drop when it is present in air merely in the proportion of 1-10,000th part.

"Recently, experiments on the effects of air containing small quantities of sulphurous acid upon vegetation have been made in Germany by my friend Professor Stockhard, of Tharand. Young Fir trees exposed two or three times for two hours to air containing only 1-20,000th, or even 1-80,000th, of sulphurous acid gas were completely bleached in wet weather, and killed when they were exposed for a longer time to air containing so small a quantity of sulphurous acid.

"In dry weather a much larger quantity of this acid may be present in the air without doing any injury to plants. It is in wet weather that air containing only traces of sulphurous acid is injurious to vegetation. In localities where much coal of inferior quality—generally rich in iron pyrites—is burned, the injury done to vegetation by the sulphurous acid proceeding from such coal may often be seen at a distance of from one to two miles from the place where the smoke is generated.

"Farmers residing in a neighbourhood where brick-kilns and potteries abound frequently sustain much more injury than they are themselves aware. The quantity of sulphurous acid emanating from open brick-kilns is very considerable, and there cannot be any doubt that in certain localities the air is poisoned with sulphurous acid gas to an extent which prevents the healthy growth of Wheat, Barley, or Oats—so that good crops are rarely seen in such localities, and blighted ones are quite the rule.

"By a recent Act of Parliament provision is made for the effectual condensation of muriatic acid gas in alkali works; but, as far as I know, there is no law which prevents brick-makers throwing into the air any quantity of sulphurous acid which they choose, although it is more pernicious to vegetation than even muriatic acid gas. I have had many opportunities of becoming practically acquainted with the injurious effects which a smoky atmosphere produces on our cereal crops, and regard a strong deposition of soot on Wheat and other crops quite a sufficient evidence of the more or less complete injury which the crops must have suffered by the sulphurous acid always present in the air in districts where such sooty deposits are seen on plants. The disadvantages of carrying on agricultural pursuits in the potteries, or in districts where volumes of black smoke discharge enormous quantities of sulphurous acid into the air, are well known amongst the more intelligent and enterprising farmers. This fact explains to a certain extent the backward condition of agriculture in such localities, and loudly calls for a mitigation of the evils to which farmers are exposed who have the misfortune to occupy land in the immediate neighbourhood of large manufacturing towns, or in localities where immense quantities of inferior coal are consumed by brick and tile makers, and manufacturers of earthen and stone ware, &c. Again, in districts where copper ore, consisting for the greater part of the sulphurites of copper or iron, are the raw materials from which copper-smelters extract the metal, enormous quantities of sulphurous acid are discharged into the atmosphere.

"The injury done to vegetation by the smoke from copper works has been traced beyond a distance of four miles. It is true that smoke from copper works generally contains appreciable quantities of arsenic, which, of course, is inimical to the health of plants; but as the arsenical fumes are insignificant in quantity in relation to the large amount of sulphurous acid which is produced in roasting copper ores, and as air containing 1-40,000th or even 1-80,000th part of sulphurous acid gas is decidedly injurious to vegetation in wet weather, I think the sulphurous acid of copper smoke does more mischief to the crops in the neighbourhood of the works than the arsenical compounds of the smoke. Just as little as alkali-makers are permitted to discharge muriatic acid into the air, copper-smelters should be allowed to discharge into the air the enormous quantities of sulphurous acid which is produced in roasting certain copper ores. It may, perhaps, not be possible to condense sulphurous acid so perfectly or as readily as muriatic acid gas, and probably the arrangements for the condensation of the former will be found altogether inappropriate to effect the condensation of the latter, but attempts to mitigate the evil resulting to vegetation by sulphurous acid fumes should be seriously undertaken.

"It has occurred to me that the sulphurous acid fumes of copper works might, perhaps, be converted economically into sulphuric acid, or be used for the production of sulphite or hyposulphite of soda; and I do not consider it improbable that one of these days this highly injurious product will cease to be a nuisance to the inhabitants of the country round about the works, and be turned to good economical account.

"As regards the actual quantities of sulphurous acid gas contained in the smoke of brick-kilns, we possess no data

for our guidance. The quality of the coal used, the construction of the kiln, and the composition of the clay of which the bricks are made, must affect to a great extent the proportion of sulphurous acid in the smoke. Thus a coal with a high per-cent-age of sulphur, but containing also much mineral matter, on burning may produce less sulphurous acid than another kind of coal, poorer in sulphur and in mineral matter, inasmuch as the greater portion of the sulphur is fixed by the mineral portion of some coals. Again, if the clay contains magnesia or lime, or is purposely mixed with chalk, most of the sulphur of the coal will be fixed by the magnesia or lime.

"The brick-makers in the neighbourhood of London, who use with the clay a considerable proportion of chalk, therefore produce a smoke which contains but very little sulphurous acid; whilst in districts where fire-bricks, tiles, &c., are largely manufactured from clay that does not contain lime or magnesia, or merely insignificant quantities, the air becomes charged with sulphurous acid to an extent which injuriously affects the vegetation for miles round the brick clamps or kilns."

ROYAL PARKS AND PLEASURE GARDENS.

An estimate of the amount that will be required to defray the charges which will come in the course of payment during the year ending 31st of March, 1865, for maintaining and keeping in repair the walls, keepers' lodges, and other buildings, the fences, roads, rides, drives, footpaths, plantations, &c., in the several Royal Parks, Pleasure Gardens, &c., under the management of the Commissioners of Her Majesty's Works and Public Buildings.

This estimate is limited to such expenses in the several royal parks and gardens as are requisite to maintain them for the public use. Expenses not connected with the appropriation of the parks and gardens to strictly public purposes, are provided for in the estimate for "Palaces."

	£ s. d.

Amount voted for the year ending 31st March, 1864, £97,952.

NOTE.—The income derived from the Royal Parks and Gardens is paid into the Consolidated Fund. The amount so paid in for last year was £3527 15s.

SIR W. J. HOOKER'S REPORT ON KEW GARDENS.

Royal Gardens, Kew, W., 1st January, 1864.

As was to be expected, the number of visitors to the Royal Gardens during the past year was below that of 1862, the year of the International Exhibition, and is as follows:—

Number on Sundays	188,484
Number on week-days	214,934
Greatest monthly attendance (July)	98,315
Smallest monthly attendance (January)	1,783
Greatest week-day attendance (25th of May)	11,631
Smallest week-day attendance (21st of November)	2
Greatest Sunday attendance (21st of June)	12,441
Smallest Sunday attendance (11th of January)	23
Good Friday (3rd of April)	9,798
Total.....	401,061

The number of intelligent visitors of all classes who frequent the museum and plant-houses for purposes of instruction have increased; and this has been even more the case with scientific visitors.

BOTANIC GARDENS.

The only important change effected has been in the great Palm-house, where three of the largest Palms, having reached the top of the house, 60 feet above the floor of the building, have had to be removed; this has been done without any accident, and their places filled by younger and rarer plants.

In last year's Report I mentioned the occupation of the great architectural hothouse, No. 1, by the broad-leaved Aroids, and other tropical plants of fine foliage. These are already growing most luxuriantly, and I anticipate that this building will eventually prove perhaps the most instructive and attractive of its kind in the Gardens. In the course of the present year it is proposed to add to its other contents a selection of tall Tree Ferns, slender-stemmed Palms, and economic plants.

Measures have been taken under the direction of the Clerk of the Works, to improve the condition of the ornamental piece of water opposite the Palm-house, which had become very foul during the hotter summer months; and an arrangement has also been made for a larger general supply of water. Flower-beds have been carried round the geometric shrubberies on the west side of the Palm-house, and on both sides of the semi-circular walk skirted by the Yew fence. Many rare and ornamental young trees have been planted on the east side of the main walk leading from the great gates. Beds of Rhododendrons will be planted on the opposite side of the same walk. It is further intended during the ensuing summer to sink in the ground on each side of the same walk a row of such small Palms, Aloes, Cycads, and other rare and conspicuous plants in pots (with their names) as can be safely exposed. This arrangement will, it is hoped, not only give this part of the garden a most ornamental appearance, but also exhibit to the public a series of curious and striking exotic forms of vegetation in the most effective manner.

The Reports on the success of Mr. Markham's introduction of Cinchona Plantations in India, and in the establishment of which (including the colonies) the Royal Gardens have taken so large a share, are very satisfactory. Mr. Markham informs me that in the nurseries on the sites selected by him on the Nilgiri hills, only three years ago, there were, on the 1st of December last, 259,396 plants, of which 66,622 were planted out; that the tallest plant is nearly 10 feet high; that two plants of *C. succirubra* are in full flower; and, further, that 6,562 plants have been distributed to private individuals.

The bark from some plants has been analysed by J. E. Howard, Esq., and the results have been entirely satisfactory.

In the Darjeeling plantations, Himalaya, under the superintendence of Dr. Anderson, there are 8000 plants, and private applications for plants have been made to that gentleman for the enormous number of 1,500,000.

In Ceylon, under the charge of G. H. K. Thwaites, Esq., there are 22,050 plants; in Jamaica, under the care of Mr. N. Wilson, 400; and in Trinidad, under Dr. Cruger, 24 plants. In the two latter colonies no attempt appears to have been made as yet to increase the stock by cuttings, a method so advantageously adopted in India.

Steps have been taken, at the request of the Government of South Australia, to introduce the Cork tree into that colony. A large quantity of young plants are being raised in the pleasure ground nursery for transport, and will be sent out in a growing condition, in glazed cases, in the early spring. For procuring the acorns we are indebted to Dr. Welwitsch, Messrs. Vilmorin, of Paris, and H.M.'s Consuls at Oporto, Barcelona, and Marseilles.

Large collections of semi-tropical trees and shrubs have been sent, at the request of the Admiralty, to the once desert island of Ascension, the upper parts of which are now clothed with trees and shrubs, chiefly derived from Kew; and I continue to receive from Captain Barnard the most satisfactory accounts of the thriving condition of these plants, and the consequent rapid increase of the fertility, water supply, pasture land, and vegetable produce of the island. The Bermuda Grass especially, which was sent from this Garden several years ago, has now become the staple fodder of the place.

Large collections of living plants and seeds have been

sent to the island of St. Helena, at the request of the Governor of that island.

An active correspondence and exchange of plants has been kept up with Ceylon, Mauritius, Queensland, Calcutta, Victoria (Australia), Trinidad, and various nursery establishments at home and on the Continent.

Besides these ordinary sources of supply, valuable collections of living plants and seeds have been received from the Rev. C. S. P. Parish, of Moulmayne; Mr. Hill, government botanist in Queensland (including a living plant of *Bowenia*, a new and most remarkable Cycad); G. Mann (government botanist), West Africa; Dr. Welwitsch, Loanda; J. J. Monteiro, Esq., Angola; Mr. Hutton, South Africa; Dr. Atherstone, Graham's Town; Dr. Imray, Dominica; Dr. Hillebrand, Sandwich Islands; Commodore Lord John Hay, China and Japan; C. H. Williams, Esq., Bahia; His Grace the Duke of Wellington, germinating seed of the double Cocoa-nut (which, however, we have failed to rear); Dr. Kirk, live plants collected during Dr. Livingstone's expedition, and others in the Seychelle and Comoro Islands, &c., including fruit of the double Cocoa-nut.

PLEASURE GROUNDS.

The principal works to be reported on are the completion of the centre of the temperate house, and the transfer to it of all the plants destined for it from the old Orangery, and other buildings in the Botanic Gardens. These, which are for the most part planted in the ground, have already begun to grow vigorously, and will soon present a noble appearance. The heating apparatus works well, and the construction of the building appears on the whole to be most satisfactory; the only exception that must be made is with regard to the opening and closing of the sashes of the roof, which will require more care and skill to keep in order than was anticipated by the builders.

Extensive plantations of trees and shrubs have been made in various parts of the pleasure grounds; and large beds of Rhododendrons, and rare trees and shrubs, are now being made along the banks of the new lake.

The chief contributions to the Arboretum have been—

Japan seeds, from Mr. Oldham, collector for the Royal Gardens, W. J. Elliott, Esq., Sir R. Alcock, &c.

Amoor River, Chinese Mantchurian, and Siberian seeds from the Imperial Gardens of St. Petersburg.

Australian seeds from J. Oldfield, Esq., Dr. Mueller, Government Botanist at Victoria, and others.

Himalayan seeds of Pines, Oaks, &c., from Dr. Anderson, F.L.S., of Calcutta, and Dr. Cleghorn, F.L.S., Inspector of Forests.

Seeds from the Nilgiri Mountains, from Mr. McIvor.

Many very fine and rare greenhouse plants from James Bateman, Esq., F.L.S., of Congleton.

MUSEUMS.

The old Orangery, so long condemned as a house for purposes of cultivation, and at last emptied by the transference of its contents to the temperate house, is now chiefly occupied with the magnificent collection of timbers, cabinet and furniture woods, from the Great Exhibition of 1862. In my last year's Report I described this collection in some detail, and enumerated the colonies and donors of the several contributions of which it consists, among which Tasmania holds the most conspicuous place for the magnitude and beauty of its specimens. Though now mostly in their places, much remains to be done during the coming year towards the fittings of the building, and the final arrangement, ticketing, and cataloguing of the collection.

The additions of importance to the Museum during the past year are:—

A specimen of Herne's Oak, presented by Her Majesty the Queen.

A collection of articles (umbrella-stick, knife-handles, &c., made of *Laminaria*, or the stem of *Laminaria buccinalis*), a gigantic seaweed of South Africa. From T. G. Ghislain, Esq.

A Fakir's richly carved drinking vessel, made of the shell of the double Cocoa-nut, together with carved articles of Shola-pith. From the Hon. W. E. Frere, Esq., of Bombay.

Articles used as barter for Palm oil with the natives of West Africa. From M. L. Levin, Esq.

Specimens of Pine Cones, Woods, &c., of North Asia. From Dr. Regel, Imperial Gardens of St. Petersburg.

A beautiful series of specimens, illustrating the mode of growth of the Mistletoe on Maple, Poplar, Hawthorn, &c. From Dr. John Harley, F.L.S.

Many curious and interesting tropical African vegetable products from Mr. Mann, Drs. Livingstone, Kirk, Meller, Captains Speke and Grant, &c.

A large collection of Barks used as drugs by the natives of British Guyana, collected by Mr. Appun, under the orders of the Colonial Government.

HERBAEUM AND LIBRARY.

Our duties in this department have rapidly increased of late, owing to the demands made upon this establishment by the various departments of Her Majesty's Government; to the number of plants sent to us, almost daily, for naming, and other information regarding them; to the receipt of large collections from several important government expeditions; to the applications for assistance and advice on the part of young gardeners and others proceeding to take charge of plantations of Tea, Cinchona, Cotton, Coffee, &c., in India and the colonies; and the redoubled activity of the Colonies in the publication of their Floras, which, though paid for by the Colonial Government, can only be prepared at Kew, or by persons in direct and constant correspondence with its Herbarium and Museums.

I have to commence my Report on this head with the announcement of the retirement of Mr. Allan Black, so long and so well known, both here and on the Continent, as the able, assiduous, and most obliging Curator of the Herbaria. Owing to the failure of his health, brought about by over-application to his duties, he has been obliged to seek a warmer climate. Most fortunately, the curatorship of the Government Gardens at Bangalore (held by a late foreman in the Royal Gardens) fell vacant at this time, and he was at once nominated to the vacancy. Our inability to find a person capable of filling Mr. Black's place at his salary, no less than the increased duties of this department, have necessitated a rearrangement of the present wholly inadequate staff, and a permanent addition to it. Professor Oliver, the Librarian, will henceforth take the joint duties of Keeper of the Library and Herbaria, and will have two assistants; he will at the same time continue his voluntary courses of lectures to the foremen and gardeners, which he has hitherto conducted with so much credit to himself, and benefit to our young men.

It is impossible, within the limits of the present Report, to do more than allude to the chief public duties performed at the Herbarium during the past year, which are as follows:—

Dr. Kirk, the surgeon and naturalist of Dr. Livingstone's expedition, arrived in England in October, and has been much engaged in the investigation of his large and valuable collections, both in the Museum and Herbarium.

Mr. Mann arrived in June from his three years' arduous and perilous botanical journey on the West Coast of Africa (including two ascents of the Cameroon Mountains, which he was the first to explore), as well as the Peak of Fernando Po, St. Thomas, Prince's Island, the Sierra del Crystal, &c. His plants, amounting to about 3000 kinds, have been all arranged and catalogued, and the duplicates distributed to the Museums of America, Paris, Austria, Prussia, Russia, Holland, Hanover, &c. He has recently been appointed assistant curator of the Government Cinchona Plantations at Darjeeling in the Himalaya. His mountain plants have been described by Dr. Hooker, and are being published by the Linnaean Society.

The British Herbarium of the late W. Borrer, Esq., presented in 1862, has been arranged by Professor Oliver.

Captain Grant's interesting collection, made during Captain Speke's expedition to Central Africa, have been brought to Kew, and have been named by Dr. Thomson, F.R.S., and published in the Appendix to Captain Speke's Travels.

Dr. Welwitsch, of Lisbon, the distinguished botanist, and explorer of the interior of Angola and Loanda, in Western tropical Africa, having been commanded by His Majesty the King of Portugal to take his collection to Kew to be named, has lately arrived with an immense Herbarium, in a most beautiful state of preservation, from those hitherto totally unknown parts of the world, and the first set is to be presented to this Herbarium.

Sir Charles Wood, Secretary of State for India, having directed the Flora of the British possessions in India to be proceeded with on the same plan as the Colonial Floras; this work (which will contain descriptions of at least 12,000 species of plants), has been commenced in the Herbarium by Dr. Thomson, F.R.S., late Director of the Royal Gardens at Calcutta.

Of Drs. Harvey and Souders' Flora of our South African possessions, the second volume is completed, and the third is in progress.

Of the Australian Flora mentioned in my last report (and which will extend to six or seven volumes, containing as many thousand species), the first volume has been published by its author, G. Bentham, Esq., F.R.S., and the second is making rapid progress.

The Flora of the British West Indian Islands, by Dr. Grisebach, has been completed during the past year, all but the Index. It contains descriptions of 3000 species of plants.

Mr. Thwaites' Enumeration of Ceylon Plants is nearly completed, and embraces upwards of 2500 species.

The "Genera Plantarum" of Mr. Bentham and Dr. Hooker is progressing as fast as the authors' other duties permit, the second part being half completed.

Dr. Hooker has been desired by the Colonial Government of New Zealand to prepare a Handbook of the Flora of that interesting group of plants. One volume is now in the press, and will be published early in the spring.

The "Species Filicum" is finished in five volumes, containing upwards of 300 plates; but a Supplement is about to appear, containing the new species that have been discovered since the commencement of the publication, together with a synopsis of all known species.

The Botanical Magazine has been conducted as formerly; the 89th annual volume, containing 72 coloured figures, and descriptions of new, rare, or interesting cultivated plants, is published.

Various papers by Mr. Bentham, Professor Oliver, Dr. Thomson, Dr. Hooker, &c., on some of the most interesting contributions to the Herbarium, especially African and Indian Plants, have been published by the Linnaean Society of London.

Other botanists who have worked in the Herbarium during the past year are Professor Babington, of Cambridge (British Rubi); the Rev. W. W. Newbold (British Plants); Mr. Edgeworth (North-West Indian Plants); Dr. Aitchison (Panjab Flora), &c., &c.

The principal contributions to the Herbarium have been:—

An extensive collection of Borneo Palms, collected by Hugh Low, Esq., and presented by Messrs. Low, of Hackney.

Large collection of Mauritius and Madagascar Plants, made by the late Judge Blackburn, and presented by Admiral Sir W. Bowles, K.C.B.

The most extensive Herbarium of Indian Plants, made by Dr. Wight, F.R.S., during thirty years residence in the Madras Presidency, Nilgiri Mountains, and other parts of the western Peninsula of India; and containing the original specimens from which his numerous and most important botanical works have been written. Presented by himself.

Very large and important collections made in all parts of extra-tropical and sub-tropical Australia and in Tasmania, by A. Oldfield, Esq.

The Portuguese and Azorean Herbarium of the Baron do Castello de Paiva, presented by that nobleman.

HAUTBOIS.—I believe Mr. Knight is right about the derivation. It is *Fragaria elatior* (higher in its stalk), and hence it is called Hautbois. The name may also be derived from the plant being found in high woods and deep forests.—W. F. RADCLIFFE.

WOOD PIGEONS.—I hope you will suggest some practicable means of getting rid of a plague of wood pigeons, which light upon the Gooseberry bushes in scores, breaking the branches, and strewing around all the Gooseberries. Query, Are they in search of caterpillars? The most cunning sportsman cannot shoot them, they are such wary birds.—A. B.

CULTIVATION OF THE MELON.

(Continued from page 64.)

Of the appliances employed for growing Melons none are in more general use than an ordinary frame on a dung-bed, which is represented in fig. 2. *a* Is a common frame 2 feet

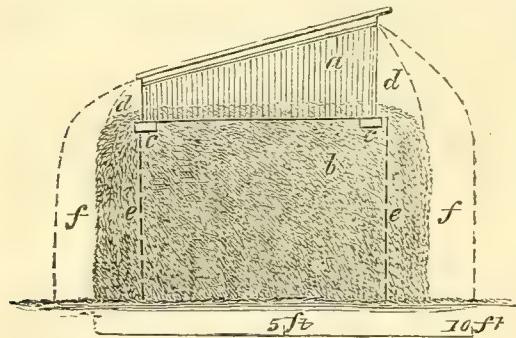

Fig. 2.

high at back, 1 foot high in front, and 6 feet wide, placed on the hotbed *b*, and resting on bricks at each corner, *c c*. The dotted lines, *d d*, show how far the frame is to have dung piled up against the sides to maintain the top heat when the bed loses its heat considerably, or when a greater depth of soil is placed on the bed. The dotted lines, *e e*, drawn perpendicularly through the bed, show those portions of the bed which are to be taken away when it becomes necessary to line the bed from the bottom, to renew the heat when declining; the space between *e e* and the dotted lines, *f f*, being filled with dung prepared in the same way as that for making the bed. The lining should not be applied at front and back at one time, but in front first, before the heat of the bed declines too much; the back lining may follow the front in about ten days or a fortnight. Linings to the bottom are only needed for early beds, and not always even then in mild seasons, for the frame will sink into the bed, and it will consequently be necessary to raise the frame up at intervals of a fortnight or three weeks, so as to keep the glass at a proper distance from the plants, or 1 foot above them. Raising the frame about the thickness of a brick each time will be sufficient, and this, with the removal of some of the spent lining, will leave a space by the sides of the frame in which some fresh hot dung can be placed, which will generally furnish sufficient heat without having the bed to line from the bottom. If, however, the heat is not maintained by top linings, the bed must be lined from the bottom before it becomes so cold as to place the well-being of the plants in jeopardy.

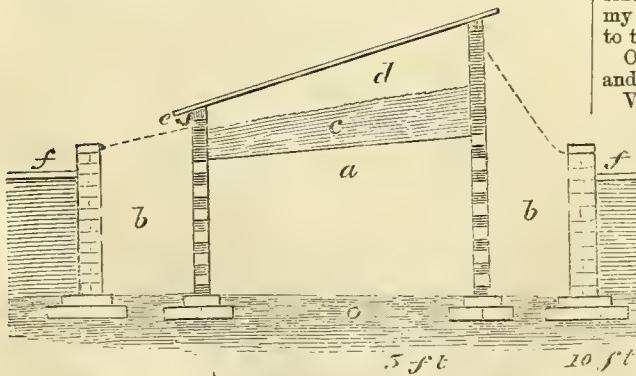

Fig. 3.

Probably the best mode of growing Melons by fermenting materials is that of a brick-pit (fig. 3), the inner walls pigeonholed to admit the heat from the linings, *b b*, to pass into the bed *a*. The inside between the two inner walls is filled up to the rafters in the first instance with hot dung, prepared, sweetened, and well beaten down and trodden at the sides. The lights being put on, the bed will be ready for

soiling in a week or ten days, previously levelling it, and adding more dung if necessary to bring the surface of the dung to within 1 foot of the glass. The soil is then placed under the centre of each light, so as to form a cone with a flattened top, the latter being only an inch or two from the glass. By the time the bed is earthed the dung will have settled, and when fully earthed it will present the appearance shown in the figure, *a* being the bed, *c* the soil, and *d* the open space for the development of the plants. *b b*, Are spaces 2 feet 6 inches wide, in which hot dung is placed; first in front about ten days after planting the Melons in the bed; and, secondly, at the back about ten days afterwards. The dung must at all times be kept higher than the pigeon-holes, and the soil within the pit should be kept close to the sides of the frame, otherwise the steam of the dung of the linings will pass into the pit and destroy the plants. The linings will require renewing, and additions of fresh dung to keep up the proper temperature according to circumstances. The linings should be brought up to the dotted line, and if they are covered with wooden shutters the heat is greater, and a cleaner appearance is given. *e* Is a spout to carry off the water, and *f f* is the ground level.—G. ABBEY.

(To be continued.)

HARDY BEDDING PLANTS WITH VARIEGATED AND COLOURED FOLIAGE.

In addition to Mr. Abbey's list, I would suggest:—
FILBERT, DARK COPPER-LEAVED, which is very distinct, dwarf-growing, and bears cutting-in well.

SALIX CAPREA VARIEGATA.—With white, green, and light brown leaves. Bears cutting-in well; strikes in a little bottom heat in a fortnight, and so might be planted for a line in a ribbon to be renewed every third year, or in most soils cuttings may be planted where required.

Both of the above would, in windy situations and in the back beds, if allowed to remain, afford an ornamental shelter of 18 inches to 2 feet or more in height.

BRAMBLE.—The Silver-leaved is very effective, but needs attention to keep it neat. I have a large-leaved Golden-variegated variety which is very striking.

VINCAS.—Besides the two named by Mr. Abbey, there is the Golden-leaved, which if well established and cut down early in the spring becomes very beautiful. I find the best way to propagate the Vincas and Brambles is to insert in the ground, in August and September, the ends of the young shoots, simply pressing them 2 inches into the earth.

There is also the fine showy Coltsfoot with a white-edged leaf; but unless grown in pots sunk in the ground it is troublesome.

The common Rib Grass would be excellent when variegated, and it is not rare to find it in the fields and by the sides of roads with both white and golden variegation; but my plants with all my care have returned in a year or two to their normal green. They also propagate badly.

Of Box some of the variegated kinds would be very useful, and nothing will bear clipping better.

VARIEGATED HOLLIES.—There are many very handsome varieties; and small plants, if nipped-in in summer and constantly taken up and transplanted, become very dwarf, and bear their pretty scarlet berries in abundance. A fine collection of these Hollies was exhibited at the Brussels Show and attracted great attention. Probably, if grafted or budded on a dwarf slow-growing kind, such as the Hedgehogs, they would be much improved and produce berries earlier in the season.

I fancy the adornment of our grounds would be at least more interesting, if these handsome hardy plants received a share of that attention which is now almost exclusively bestowed on summer bedding-out plants.—W. WOOLER.

DESTROYING ANTS.

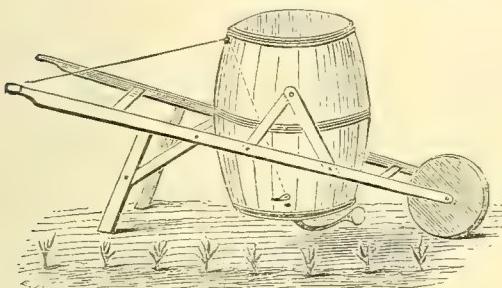

THE following is related by M. Garnier, in a communication to the Central Society of Agriculture, at Brussels:—A large colony of ants extending their walks over an area of nine or ten yards, gave great trouble in the garden. After

trying various ineffectual means of destroying them, I placed near their haunt several small saucers filled with sugar and water, in which was mixed one-tenth of the weight of white oxide of arsenic. I watched them for about an hour, during which time many came to drink, and went away staggering, taking with them one or two which were dead. In the course of two hours not an ant was to be seen, and the next morning the anthill was entirely deserted.

Why was this? The arsenic was not dissolved. Had they from instinct discovered that attempts were being made to destroy them? I am unable to say. I merely state the fact, and leave it to the investigation of others.—A. S., Bruges.

A WATERING-BARROW.

In describing this barrow it is desired to bring into notice not only a very useful apparatus, but also one that every gardener may make for himself. There are plenty of excellent machines for watering gardens, but they cost money. In nine cases out of ten this one need not cost a penny.

The arrangement, as may be seen by the cut, is very simple. Having selected a good watertight barrel, put through it a strong wooden bar, with the ends rounded and projecting 2 or 3 inches from the sides. This bar should be about a foot from the top of the barrel. A hole is then bored in the bottom of the barrel, and a piece of leaden pipe, about $2\frac{1}{2}$ feet long, inserted and secured. A valve with a leather hinge is placed over this hole. A string from the valve is passed over a pulley, near the top of the barrel. This being done, mount the barrel on such a barrow as is shown in the cut, put a rose upon the leaden pipe, fasten the valve-string to the right handle of the barrow, and the machine is made. If there are no unused barrow-wheels on the premises, one may be made by sawing two thick pieces of plank in a circular form, and nailing them together, with the grain of one at right angles with the grain of the other. Bore and chisel a square hole in the centre of this, and insert an axe, which is of easy construction.

The peculiar convenience of this watering-barrow is that it may be wheeled along a row of vegetables or flowers, and by pulling the valve-string with the fore-finger of the right hand, the water will flow from the rose until the barrel is empty, and the row will be watered with very little trouble and much expedition. If another pipe and rose be placed so as to project from the other side, both valves may be worked as easily as one, and two rows may be watered at the same time. The pipe being flexible, may be bent so as to suit the distance between the rows, the height of plants, &c. This apparatus is particularly adapted to places where there is much "row-watering" to be done.—(*American Gardener's Monthly*.)

THE ROYAL ASHLEAF POTATO.

ALTHOUGH we possess many really good sorts of this most useful of all vegetables, and consequently are rather fastidious in this respect, the appearance of the above new kind excited a good deal of interest, and I was one of those who eagerly procured a certain number of "sets" for early planting.

This was done on the 10th of April, in well-prepared ground, which had previously been manured with well-

decayed stable-dung, mixed with rotten Oak leaves. On the same day I planted an equal number of the following kinds, the tubers being as far as possible of the same size—viz., the old Ashleaf, Gloucestershire Kidney, and Myatt's Early Prolific.

The first two proved the earliest, their tubers being fit for use on the 25th of June, when the haulm of Myatt's likewise commenced to dry; whilst the Royal Ashleaf still continued growing. So far as to earliness.

As regards the produce, the old Ashleaf, as usual, yielded only a scanty crop; the Gloucestershire Kidney about twenty-five per cent. more, and the tubers more regular in size and shape. Yesterday (July 30th) I had the whole bulk of the four sorts taken up, and found Myatt's Prolific by far the most productive; whilst the Royal Ashleaf, upon the whole, proved not more prolific than Gloucestershire Kidney, and in flavour equal, though not better than Myatt's.

The Royal Ashleaf seems to have one great drawback, some of the plants being quite dead, whilst others in the same row had the haulm quite green. I am satisfied that I possess the true sort, having obtained my seed from one of the most respectable London firms.

Of other new Potatoes which I tried, Daintree's Seedling (now ripe) is a very prolific, good-sized, round Potato, with a very rough skin, white flesh, quite mealy, and delicious. Epp's Glory is still growing vigorously, in spite of the prevailing drought, and apparently a latish sort.

I shall repeat the experiment with the four above-mentioned Kidneys next year, and plant a certain number of tubers of equal weight, so as to be able to judge which of them yields the greatest proportion in weight.

I must add that the spring frosts in this part of France were not of sufficient consequence to have the least influence upon the growth of Potatoes.—FERDINAND GLOEDE, *Les Sablons (Seine et Marne)*.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CORYLOPSIS SPICATA (Spiked Corylopsis). *Nat. ord.*, Hamamelidaceæ. *Linn.*, Pentandria Digynia.—A Japan shrub, introduced from Yokahama by Messrs. Veitch, of the Royal Exotic Nursery, Chelsea. Flowers yellow, fragrant like the Cowslip. Blooms in February. "Shrub deciduous, and the flowers appear before the leaves, which are so much like those of our nut bushes as to suggest the name of the genus."—(*Bot. Mag.*, t. 5458.)

DENDROBİUM EBURNEUM (Ivory-flowered Dendrobium). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Sent to Messrs. Hugh Low & Co., Clapton Nursery, from Moulmein. Flowers "have exactly the appearance of polished ivory," having dark red lines on the lip and base of column.—(*Ibid.*, t. 5459.)

KALANCHOE GRANDIFLORA (Large-flowered Kalanchoe). *Nat. ord.*, Crassulaceæ. *Linn.*, Octandria Monogynia.—Native of Mysore, Hindostan. Flowers yellow. Bloomed in a greenhouse devoted to succulents during May.—(*Ibid.*, t. 5460.)

DELPHINIUM BRUNONIANUM (Mr. Brown's Musk Larkspur). *Nat. ord.*, Ranunculaceæ. *Linn.*, Polyandria Monogynia.—"This handsome species is a native of Western Thibet, on the mountains at altitudes of from 14,000 to 18,000 feet, where it flowers in August and September." In England it blossoms in the open border in June, and dies down early in July. The flowers are pale blue, streaked with purple, and black in the centre. The whole herb has a strong musky scent.—(*Ibid.*, t. 5461.)

CELOXYNE ODORATISSIMA (Highest-scented Ceoloxyne). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of Neura Ellia mountain in Ceylon, and the Neilgherry Hills of Madras. Grows on trees. Flowers in this country have a honey-like smell; they are white, appearing in April. It would seem to prefer shade, as in its native places it is always found on the north side of the hills.—(*Ibid.*, t. 5462.)

APHELANDRA LIBONIANA (Libon's Aphelandra). *Nat. ord.*, Acanthaceæ. *Linn.*, Didynamia Gymnospermia. Probably a Brazilian plant. Bracts bright orange; flowers yellow tipped with red. Flowers during May in a warm stove.—(*Ibid.*, t. 5463.)

FANCY PELAEGONIUMS.—*Anne Page*, very round outline; bright crimson-rose top petals; lower ones lighter, all white-edged. *Edgar Turner*, dark crimson upper petals, with a brighter crimson edge; lower petals same colour, but shaded off paler, until in the throat quite white. Both raised by Mr. Turner, Nursery, Slough.—(*Floral Mag.*, pl. 205.)

RHODODENDRON.—*Princess Alice*. Raised by Messrs. Veitch by crossing *R. Edgeworthii* with *R. ciliatum*. Flowers large and pure white.—(*Ibid.*, pl. 206.)

TELS.—*Mademoiselle Patti*. Raised by Mr. Salter, Versailles Nursery. Upper petals orange; lower petals claret, darkly veined: bases of petals yellow veined with claret.—(*Ibid.*, pl. 207.)

SARRACENIA DRUMMONDII.—Pitchers green; tops white veined with green.—(*Ibid.*, pl. 208.)

ROSE.—*Lord Macaulay*. “Full, deep, and richly coloured, it takes an honourable place among the thoroughly good crimson Roses which have been rather bountifully added to our collections during the last two or three years. We owe the opportunity of figuring it to Mr. W. Paul, of Waltham Cross, by whom it was obtained from the continent, and who first introduced it to the notice of British rosarians in the spring of last year; the flowers then exhibited winning, most deservedly, a first-class certificate.

“When recently lecturing on Roses at South Kensington, our friend and correspondent, Mr. Radclyffe, observed with much truth, that none but vigorous-growing Roses were suitable for our English climate—this vigorous character being, however, just what it too often happens that Roses of continental origin are deficient in. In this respect we are glad to be able to attest that Lord Macaulay will fully meet the requirements of English growers; the habit being strong, the foliage bold and ample, the flowers of full average size, the form cupped, the petals firm and smooth, and the colour a rich crimson. As regards colour, indeed, the flowers are variable. Sometimes they are richly shaded with very deep, almost maroon crimson, and sometimes they are of an almost uniform deep crimson, as our figure represents them; and sometimes, as was the case with the blooms shown on the occasion of Mr. Radclyffe’s lecture, the margins of the petals are of a glowing crimson scarlet. In any of these conditions it is a beautiful Rose of high merit. We have, therefore, no hesitation in recommending it heartily to the notice of Rose-growers as a flower of quality and refinement, combining with the richest colouring a perfectly free and vigorous habit of growth.”—(*Florist and Pomologist*, iii., 169).

THE EDUCATION OF THE EYE.

A WELL-EDUCATED eye is always an advantage to its possessor, but few professions afford greater scope for its acquirement and exercise than that of a gardener. Most gardening operations require a clear discriminating eye, and a steady hand. Wherever you find an amateur whose productions and general management are equal to those of many practical gardeners, you at once set him down as one who is “quick to learn and wise to know,” for his skill and taste are the result of his own observations and experiments. Although a liking for a pursuit generally leads to some degree of skill in it, yet there are men who do one or two things well, and the rest of their work very indifferently. Take, for instance, your amateur friend who makes Dahlias, Pansies, Marigolds, or any particular flower his chosen hobby. He shows you some very fine flowers on robust plants; but then you must shut your eyes to the rest of his garden, or else your admiration of his flowers will be extinguished by your dislike of disorder and weeds—that is to say, if you have an educated eye. Some people say this class of men are incapable of more than one idea—it is Pinks and nothing but Pinks with them (or some other flower, as the case may be); and although their Pinks may be good, their gardens are far enough from being the pink of perfection. Is it not strange that the eye that can admire the symmetry and charming combination of colour which distinguish florists’ flowers, should sometimes be wholly insensible to the enhancing beauty of cleanliness, neatness, and order in garden management? Yet so it is, and there is no accounting for it, otherwise than by the want of what may be termed eye education. You will often enough see

men put away their spades, trowels, or other tools without cleaning the dirt off them. Now, not to speak of the pleasure there is in using a bright implement, and the finer work you can make with it, some people would clean it and make it bright after use simply for the pleasure of seeing it so. This sort of thing is illustrated by the saying that one sometimes hears regarding the mistress of a house, “She has a keen eye for dirt.” When you see a plot of Dahlias so well staked and tied that every shoot is brought into the best position for receiving light and air, and the straggling or useless branches carefully pruned away, you are the more surprised if you find the border flowers that grow along by the walk all hanging in tangled masses, entirely at the mercy of the wind and rain. In a case like this you say, “Well, this man may be a good Dahlia grower, but he has no eye for anything else in his garden;” and you are not far wrong. It is not unlike what housewives call a “clean middle and dirty corners,” when they want to point out a sister’s deficiency in the domestic virtue of cleanliness. These are results of defective eye education that no Diogenes would require a lantern to discover. They are open, glaring, obvious, and wherever they exist they are as ugly as they are apparent. Again: when an amateur takes you to see his favourite plot of flowers, and you have to pass along a road that is barely passable, you naturally suppose that gravel and engine-ashes must be at a high premium in that quarter, and entirely beyond your friend’s reach. But, on the other hand, it must be conceded that where these garden defects are to be found, they are not always to be taken as indications of defective eye education, or want of taste. Amateurs are often hard pressed to get their favourite flowers attended to, and however much they may desire to have everything trim and shipshape, the time they are enabled to bestow on their gardens is wholly inadequate. You can generally see, however, whether a man is of a tasty turn by the way in which he does what his time permits him to do, and eyesores will, under every circumstance, remain eyesores to the educated eye. The very fact of there being such a word as “eyesores” proves that some eyes are more defective than others.

Most men have heard or used the expression, “He has not a straight eye in his head,” at some time or other; and this very common, but not very complimentary phrase, indicates either the careless use or the imperfect training of the eye. One ploughman makes straight furrows, and another makes crooked ones; one man makes even work with his spade, while another leaves the ground in hills and holes; one gardener can clip a Box-edging as straight and clean as if he had chalked a line to go by, as a tailor has when he cuts out a coat, but his neighbour performs the same operation in an out-and-in style, which is less pleasing to the eye. This may not be so much a defect in the education of the eye, as in the hand and eye not working together, or the hand not being trained to obey the eye. He may perceive that his work is not well done, and be dissatisfied with it. But when a gardener can go complacently past the yellow and decayed leaves on his greenhouse plants, when he has time to remove them, you may be sure his eye education is defective. So in bedding-out for summer decoration, you will find one gardener make far nicer work than another, not in arranging colours and sizes for back or front positions, for that is often done according to a fixed plan, but in the regularity with which he places each plant at the proper distance from its neighbour when he has only his eye to guide him. The same thing may be observed in a hundred different forms. One eye cannot bear to see a crop of weeds and moss growing along with plants in pots, nor slimy vegetation covering the sides of the pots, nor gaining a foothold on the flags of a greenhouse, while to another these things are no eyesores at all. So with the plants in a greenhouse or stove; a gardener with what is called a good eye will make a far more effective arrangement than one who has neglected his eye education. It is the same in potting: one man will detect a wireworm, or anything else of an injurious character, and cast it out, while another will shovel everything into the pots, perfectly unconscious that he is doing his best to spoil his own work.

Budding and grafting require an educated eye, for on the skill and nicety with which these operations are performed depends, in a great measure, their success. But for all that,

you will find some who do not see that a clean cut and a nice adjustment of the bark of the stock and scion are essential in grafting, nor that in budding it is at all important not to break the inner rind, nor to pull the eye out of the bud in taking away the wood. Such practitioners wonder that they have so many misses; but the wonder should be the other way, for their hits belong to the chapter of accidents. On the whole, then, it is beyond doubt that some eyes afford evidence of a higher education than others. It is perhaps equally certain that some eyes are naturally endowed with keener and finer powers of perception than others. But it may be safely asserted that careful training will render the eyes of all equal to the work they have to perform, and capable of complying with the demands of good taste. A great point is gained when a man can see that his eye needs anything in the way of education. This is the first step on the road to a clear, discriminating, and tasteful vision. It is sometimes said of a person that "He has an eye like a hawk, and that nothing escapes his notice," but this power can seldom be attained without a close and lengthened practice of observing minute details. Careful inspection of the forms of flowers and parts of flowers, as well as of the leaves and seeds of plants, such as the study of botany involves, is excellent training for the eye. From small things it gradually begins to appreciate and love the harmony of Nature on a larger scale, and the result is a quick discernment of beauty and deformity, or what we may call the fitness of things. Thus by practice and painstaking, the eye acquires a natural but not conventional liking for nicety and order, and that valuable faculty of arranging, combining, and suggesting, on which the occupation of a gardener or florist makes incessant demands.—*AN OLD SPADE.* (*West of Scotland Hort Mag.*).

WORK FOR THE WEEK.

KITCHEN GARDEN.

To those who would insure a constant succession of choice kinds of vegetables and salads, the next fortnight will be the most important of the whole year. Should the present dry weather continue, the water-barrel will be in constant requisition morning and evening. Surface-stirring must also be frequently resorted to for the purpose of preventing too rapid evaporation. Carrots, now is a good time to sow the Early Horn to stand through the winter. Endive, planting must now be proceeded with in earnest, for what is now planted will constitute the great bulk of the autumn and midwinter salads. Let elevated beds of 4 feet in width, and possessing a bold curvature, be provided in an open and dry situation. Such beds should be a foot or more above the ground level, and must be made very rich. These beds may be hooped over in the end of October, to be readily covered with mats when frost arrives. Lettuce, keep up successive sowings of this and of Radishes, the growing crops of which must be liberally supplied with water. Onions, sow a good breadth of winter Onions; the Strasburg and Tripoli are good sorts. Sow thickly for drawing young for salads and for transplanting. Let the ripening Onions be bent down by hand in order to get the ground clear for Winter Greens. Parsley, sow for winter and spring use. Spinach, about the middle of the week is the proper time to sow Prickly Spinach for the winter. The ground should be good, but not too richly manured, as it is apt to make the plants grow too strong, which renders them more liable to injury from frost. Whatever remains undone in the way of planting-out Broccoli and Winter Greens must be completed without delay. Pay due attention to the thinning-out and surface-stirring amongst all advancing crops. Gather and store seeds of such choice vegetables as if may be considered advisable to preserve; but anything very extensive in this way ought never to be attempted in gardens exclusively devoted to the purpose of cultivating vegetables for families having any pretensions to taste, as in most cases disappointment and inferior quality will be the result. Whoever is conversant with the nature of kitchen-garden produce is well aware how much the qualities of vegetables become deteriorated when grown, seeded, and produced on the same ground year after year.

FRUIT GARDEN.

The preservation of wall fruit from birds and insects should

occupy attention. Haythorn's hexagon or any other small-meshed netting may be employed with advantage to protect Green Gage or other Plums. Look carefully over Peach and Nectarine trees, and remove nails which are too close to the swelling fruit. In stopping and arranging the wood let only as much as can conveniently be laid in be allowed to remain, and that convenience must be qualified by due consideration for the perfection of the fruit and the proper ripening of the wood, which only the influence of the sun and air can accomplish. It is also an error in another respect to retain a large amount of wood to be removed at the winter pruning, for an undue excitement and extension is given to the roots, which, with a superabundant supply of sap, induces in the spring the growth of rank and unmanageable wood. Pear shoots which have been left, or only partly shortened, should now be pruned back to three or four eyes. Proceed with Strawberry planting. Remove runners from established plants to relieve and strengthen them.

FLOWER GARDEN.

Much watering will be necessary here during the great heat we now experience. Advantage must be taken of the first shower of rain to put out young seedling Wallflowers, Brompton Stocks, Sweet Williams, and other biennials into nursery-beds. Hollyhocks are general favourites, but they do not afford cuttings freely, and are in general not over-plentiful about most places: these should, therefore, be examined often in search of cuttings which they may afford, as those rooted about this time will make strong plants for next season. Attend to the tying-up of these and Dahlias, and frequently go over the masses of Verbenas, &c., for the purpose of regulating the growth, so as to keep it orderly and neat. The present dry weather has been rather prejudicial to Polyanthus. After rain put out seedlings; a north-east border will be most suitable, the soil of which should be composed of loam, decayed leaves, and cowdung reduced to a black unctuous mass, in about equal proportions. We would again urge the necessity of layering Carnations and Picotees without loss of time. Attend to the gathering and saving of choice perennial and biennial flower seeds; these should be watched daily, and collected as they ripen. We do not urge this operation to be carried on to a great extent, as the returns would not be adequate to the expense and trouble of collecting and cleaning them. We merely allude to those showy species and varieties, some of which every flower gardener possesses and cultivates, and which it is desirable to preserve.

GREENHOUSE AND CONSERVATORY.

It will be much to the advantage of the inmates of plant-houses to reduce the shading after this time to enable the plants to ripen their summer's growth, allowing more air to keep down the temperature and to check any tendency to a second growth which may show itself, and which can only take place at the expense of next season's bloom. Remove Achimenes, Gloxinias, Tuberoses, and plants of the same habit from the conservatory when on the decline. Passifloras and, in fact, the greater part of conservatory climbers will be growing fast and will require frequent training. Epacries, winter-flowering Heaths, and other things requiring to have their wood ripened early, may now be placed in a sunny exposure. As the wood is already formed nothing remains but to get it ripened; and although sufficient water must be given to supply the demands of the plants, a dry and warm atmosphere are essential to the perfect ripening of the wood and consequent formation of bloom-buds. The different varieties of Epiphyllum, if their growth is sufficiently advanced, should have similar treatment. Give a shift to Chinese Primroses and Cinerarias. Chrysanthemums, Salvias and other autumn-blooming plants should be placed in their blooming-pots.

STOVE.

Various stove climbers as Combretums, Quisqualis, Allamandas, &c., will bloom for a considerable time if the shoots on which the flowers are borne are slightly cut-in when the blooms decay, and anything which prolongs the period of beauty with those favourites is worthy of adoption.

PITS AND FRAMES.

Where bedding-out on a large scale is practised, the propagation and preservation of the annual supply of plants becomes an important part of the gardener's duty. That

the result may answer the expectation at bedding-out time, a careful calculation of the number required and the means there is of preserving them through the winter should be made. The next thing to consider is the kinds which require immediate attention to get them established before winter, those which may be deferred a month or so longer, and, again, what can be propagated in sufficient numbers in the spring, provided a few store-pots of each are kept for the purpose. In the first class we may place nearly all the varieties of Fancy and bedding Geraniums, Crassulas, Lantanas, Mesembryanthemums, Hydrangeas, and plants of similar habit which require to be established before winter.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

OWING to the parching drought the work here has been of a routine character, as it was hopeless to think of planting anything out, the ground being like dry ashes, and there being no water to give to anything planted out. It surprises us that things continue to grow as they do, and they never could have done so but for the deep stirring of the ground in the first place, and frequent surface-stirring in the hottest days. Cauliflowers, in addition, have had fully 6 inches of short litter thrown closely between the rows, and firmed up to the stems, and they are looking as well with this mulching as if they had been watered twice a-week.

We have now taken up all the Potatoes, a fine crop, and, as yet, not a speck of the old disease. We have put them in small heaps, with dry earth and ashes sprinkled among them. Two years ago, though the Potatoes showed no signs of disease when taken up in dry weather, like the present, they began to get diseased a month after they were housed in equally good condition, and when placed together in such small quantities that anything like heating was out of the question. Then, in addition to dry soil, a little powdered lime was also scattered amongst them. After all that has been said of this disease, we seem to know little more about it, as to its cause and cure, than we did on its first appearance amongst us. Amongst things to which we ventured to give a little water was Celery, as otherwise we were afraid it might throw up its flower-stalks. Immediately on giving it the sewage water, we covered the ground between the plants with 2 or 3 inches of half-rotten tree leaves. If that is not enough, we must use litter. Water is now with us becoming almost as valuable as wine—a fact which we hope will be borne in mind by those friends who have written respecting changing the position of their garden, and especially from the neighbourhood of a never-failing pond to a site where there is at present no water. Philosophise as you will, you cannot but feel annoyed when, after having got all things in tolerable order, you find them decaying and dying before your eyes, and you cannot give even a drop of water to save them.

Something also akin to envy will be apt to creep over you when you hear of other people being so well situated in this respect. One of our friends has the charge of a pretty flower garden in front of the mansion, on ground about as much elevated as ours, and he used to know what it was to be without water in summer. A stream goes through the valley, however, forming a large lake, and a water-ram constantly going now supplies a large elevated cistern, and the turning of a tap and a long piece of hose enable a man easily to flood all the beds, and grass too, in a short time. We have heard this morning from the able superintendent of the Liverpool Botanic Gardens, and whilst we are parched up he tells us that some things are suffering from too much rain. Last season the flower-beds there were magnificent; but though we took notes of them in a deluge of rain, we have not yet been able to tell what we saw. We have heard that the flowers are even, if possible, more attractive this season. On our visit last year we had some experience of the delugings to which our friends in the west are subjected; and Mr. Tyerman would do good service by giving a list of the plants that do best under such circumstances, as even here we find that there are plants that seem never to have too much wet, whilst there are others that do little good unless they have a clear rather dry atmosphere.

FRUIT GARDEN.

Much the same as in the previous week. Have been obliged to throw some whitening water over the glass to lessen the evaporation of moisture within, and find that with all this prevention late Grapes and fruit in the orchard-house will be apt to colour and ripen too soon, owing to a deficiency of moisture at the roots. We have managed to give them a little sewage water, but not a fifth part of what we would have liked to have given them. Figs, whose first crop is now nearly over, we have also watered well, and then covered the soil with tree leaves, and kept the house closer to bring on the succession crop. Some plants in pots in the orchard-house will keep up the succession. All the pots in the orchard-house, and part of the soil, have also been mulched with half-rotten leaves, in order to lessen the necessity for watering often. The most of the pots are so heavily laden that some visitors have twitted us about not taking part in the orchard-house controversy, but we have already more irons in the fire than we can attend to properly. With such demands for moisture, and reservoirs empty, it need excite no surprise that the sky and the barometer are the last things to be looked at at night and the first in the morning.

Where Melons have been lately planted out, we manage to give them a slight syringing in the afternoon. For plants ripening their fruit we stir the surface of the soil to prevent cracking and over-drying, and give a little water to the roots beneath, by pouring the water down pipes left on purpose. The drier the atmosphere, not to be parching, the better will the flavour be. We have been desired to answer here some inquiries as to the best soil for Melons. One friend says that he can obtain no earth except that from his garden, which is a loam rather stiff than otherwise, and that he is nonplussed with long details of separate component materials for forming a suitable compost. No wonder. For ourselves we prefer simplicity, and we could not have a more suitable compost for Melons than such a garden soil if we searched the country through. To have it fresh, however, we would prefer the under spit to the top spit; and if the plants were a good size when turned out—say in six-inch pots, we would use no other soil whatever, but merely place some of the finest and best aired round the roots, and squeeze all the rest tightly with hands and feet, as under such circumstances it will be pretty moist. If the plants are smaller, then from the surface of such soil ridged up in winter we would collect a few barrowloads in the spring, and keep it for placing a few shovelfuls round each plant. In each case after the firming, the surface may be left a little open and loose, to prevent cracking, and the too rapid evaporation of moisture. Such soil will in general be better without any manure at all. If the Melons are not strong enough, manure waterings can be added at pleasure. But in such bottom-spit garden soil this will be rarely required.

Another friend has a light sandy soil. The best thing he can do is to have a little clay, or strong loam to mix with it. Without anything of the kind, however, his light soil will do very well with a little rotten dung added to it if poor, and if made rather moist before using, a depth of at least 18 inches given, and the soil well firmed by mallet, and hands, and feet, as it is put in. So firmed, with a sprinkling of leaf mould on the surface to prevent drying, we have grown fine Melons in very light soil. The firming the soil is in such matters half the battle, and is of far more importance than a dozen of varied materials nicely mixed together.

ORNAMENTAL DEPARTMENT.

General routine as to stove and greenhouse plants, removing Balsams, &c., from conservatory, and supplying with Coleus, Begonias, Browallia, Thunbergia, &c. Putting more whitening on roofs to shade, and thus lessen watering, as by this means we could also lessen the amount of air, and thus prevent so quick drying up. Syringed floors and stages with the same object in view. These matters, of course, would be of less importance where water is plentiful, but, where at all scarce, a nice moist growing atmosphere can thus be kept up at the smallest amount from the water-pail. The same practice will also be valuable for lessening labour, and generally that is not too plentiful.

Some gentlemen and ladies are most honourably straightforward in this respect. They know their own circumstances

best, and may well consult their own tastes as to how they will spend their income. When the gardener is anxious to have some addition or some improvement made, they may tell him that they have no objection whatever, provided no additional expense is incurred and no additional labour in keeping up is required; as on these matters their mind is quite made up. If we gardeners get into a fix after this as respects labour we have only ourselves to blame. One thing many of us forget, which is simply this, that a small place well kept is far more satisfactory to all parties than a large place, the work of which can never be mastered from January to December. The best thing in such circumstances is to keep the principal parts well and let the rest go wild. When some people go to a large well-kept garden and begin deprecating their own little place, and say they will lose all zest and interest in it, it would make us very sorry but for the conviction that the illusion would only be of very temporary continuance. Small gardens ought to be the best managed. If a brother workman has a single flower-bed more beautiful than the Duke of Sutherland possesses at Trentham, he may well divide the honours even with a Henderson. We candidly own, that in small places we have seen single beds of flowers, that out of our many beds we should have found it difficult or impossible to find a bed equally good in all its properties. Extent is apt to bewilder, but for comparison we should come back to quality. Hence the florists with their few yards of ground may well claim more than equality with the largest gardens. The cultivation of the sense of the beautiful wherever found, is the best antidote for even the rootlets of everything like envy or covetousness.

In the flower garden the sun has pretty well done all the mowing and machining for us, but the grass is now becoming green. As yet the flower-beds have kept going on pretty well, independently of the drought. What have chiefly suffered are the Calceolarias and Salvias. We have never had the former better. As yet we have saved them chiefly by mulching, and a few homeopathic doses of liquid. Without water we fear another week will finish them. In our ground they would not disagree with a nice shower three or four times a-week. A wet season, therefore, suits them better than a dry one. Scarlet Geraniums on the other hand, that have scarcely had any water after they were established after planting out, seem just to be in their element. Their foliage covers the ground, and the bright sun and dry atmosphere just suit the large corymbs of bloom.

This may, therefore, be an appropriate place to say a few words in answer to some inquiries respecting *planting out Scarlet Geraniums* at once, or plunging them in the pots in which they grow. The proper course to pursue will depend almost entirely on the natural or the artificial supply of moisture. We have previously mentioned four large Geranium plants that have been in the same pots many years, and which have the pots plunged in the flower garden. In wet summers these plants were always great balls of scarlet, because the roots were confined and comparatively dry, whilst beds of Scarlet Geraniums planted out were only middling as respects blooming, the foliage being abundant and requiring much thinning. These four plants are also good this season, but at the expense of watering them twice a-week, whilst, as stated above, those planted out have had none, and are pretty well as much supplied with bloom in proportion to their size. We could manage to water these few plants, but, for hundreds and thousands, we must have let them take their chance; and if these had been in pots we know they would have been scarecrows by this time without watering, whilst planted out they are very fair indeed without any watering.

The inferences we draw from these facts, then, are—that in dripping, rainy districts, as about Liverpool and Glasgow, or where water can be given in abundance where required, Scarlet Geraniums will bloom best if turned out with their five or six-inch pots plunged in the ground, as the confinement and comparative dryness of the roots will encourage bloom, and discourage excess of foliage. But, on the other hand, in districts where there is generally little rainfall in summer, and in places, especially, where watering cannot be resorted to, it will be found best to turn the plants out in the usual way, without their pots. In some wet summers and

autumns some beds in which Scarlets were plunged with their pots were magnificent here, whilst others planted out were rather too much disposed to give foliage instead of extra bloom. Both in the last and present summer the beds of plants turned out in the usual way have done very fairly, and give healthy foliage and fine trusses without a drop of water. The four fine plants that have been, we think, seventeen years in the same pots, and are plunged in the centre of beds in their pots, and which show after three days at most that they need another drink, just tell us that our beds of Geraniums had been in a woful plight if they had consisted of plants turned out with their pots plunged, and we could have given them no water. With a little water we have been able to keep Calceolarias alive as yet. With no more at our command, and Geraniums plunged in pots also needing help, it is most likely that both would have perished.

The character of the district, then, as to rains, and the supply of water when needed, are the best test to regulate our practice. So apt are Geraniums to become over-luxuriant in wet summers, that we would be much disposed to plant out and plunge them in pots, could we give water when the season proves a dry one. In such a season as this in Hertfordshire, most likely the most of such plants would have dried up and died before now, if there were nothing better than rain water to depend upon. Circumstances, therefore, become the best regulators of our practice, and what would be the best practice at Liverpool might not be the most suitable one here, and still less so along the dry east coast. In catering for the interests of all cultivators, the practice and the testimony of practical men in different localities will ever be most valuable.—R. F.

COVENT GARDEN MARKET.—AUGUST 6.

The long continuance of dry weather has affected the supply less than might have been expected; still it must be remembered that the demand is less, owing to families going out of town. Hothouse Grapes and Pines are sufficient for the demand; Peaches, Nectarines, Gooseberries, and Currants, plentiful; Strawberries and Raspberries scarce; Apples and Pears are coming in in quantity. Imports from abroad consist of Pines, Apricots, Pears, and heavy consignments of Plums. Cabbages and Cauliflowers have advanced in price.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

STRAWBERRIES (*J. B. Y. N.*).—You can obtain the information you seek from Mr. Rivers, Nurseries, Sawbridgeworth, Herts.

BOWNESS (*A Glasgow Subscriber*).—We do not know the party you mention.

BOOKS (*T. P.*).—The "Cottage Gardeners' Dictionary" is just the thing for you.

PEAS FOR SEED (*A. R.*).—Peas for seed should be sown rather thinly in rows about the middle of March, allowing the same distance between the rows as the kinds respectively attain in height. The treatment given to Pea crops generally applies to those for seed—that is, earthing-up, staking, and hoeing between the rows. When the pods towards the extremity of the haulm become white the crop should be pulled up, and laid on the sticks for a few days to dry. They are, after drying, placed on a dry hard floor and beaten out with a flail. The Peas are then sifted to free them of dust and seeds of weeds, and stored away in bags, or on a dry floor.

LAPAGERIA ROSEA (*E. P.*).—You need not fear about the air, only give abundance of water at the root. You cannot give it too much air, if only the current is not strong, and that it cannot be with the netting to keep out bees. We think all will be right.

VALLOTA PURPUREA—CEERUS HEXAGONUS (*C. M. Major*).—You may separate the roots immediately after the blooming, or, perhaps better, in April. In future avoid deep planting. It is very detrimental to this beautiful Lily, and yours rising above the soil is a proof of what it likes. The Cereus may have its top cut off now. This should be done with a sharp knife transversely at the required height. The part intended to strike should be exposed for a few days until the wound is dry and covered with a kind of skin. It will then strike or root freely in any light poor sandy soil. This is a bad time for grafting the stock. Such operations are best performed when the stock commences growing.

THRIPS ON FRANCISCA (*Z. Z.*).—The black insects on your leaves are thrrips. Make a solution of 4 ozs. of soft soap to a gallon of soft water at 120°, and dip the plant in it for about one minute, allow the plant to dry then repeat the operation, and wash afterwards with clear water, or sponge, every leaf on both sides with the above solution. Fumigating with tobacco will also destroy thrrips.

NEW VINEY (*H. R. D. P.*).—We presume you can go no higher than 7 feet at back. Then for Grapes in June we would have no more than a height of $\frac{1}{2}$ feet in front. If the ten-feet width inside is on the same level, or a little higher than the outside, you could plant inside, and have the front wall on arches; or you could make your front boundary of posts and boards, and have ventilators in the boards. If you sunk the house inside to give you more head room, unless you kept the roots there, or had extra drainage, you would need to plant the Vines outside and take the stems into the house. This plan would give you more room inside. Without this sinking, you might have more head room by taking a short hip, say $\frac{1}{2}$ feet from the top of the north wall to a ridge-board, say $\frac{1}{2}$ feet from the floor level. You might have four or five openings on pivot hinges in this hipped roof, and, with ventilators in front, all your roof could be fixed, and glazed with large squares. It would also be as well to have a corner-piece of 18 inches at each end next the apex made to open. The fine ought to be 1 foot in width, and from 15 to 18 inches deep outside measure. We shall be glad to assist if we can.

CAMPYLOBOTRY REGALIS CULTURE—MIMULUS (*Rossetti*).—The Campylobotrys is rather difficult to keep in good condition. It delights in a moist calm atmosphere. It is extremely susceptible of injury from water standing on the leaves, sudden changes of temperature, and currents of cold air. By keeping your plant in a close humid part of the stove, in a diffused or not strong light, yet near the glass, and preventing cold, damp, and stagnant air lodging near it, with good drainage and sweet soil, we think the leaves would retain their beauty much longer. Cuttings of Mimulus struck now will make nice plants for blooming in the greenhouse next spring; but after blooming once in the greenhouse they are not suitable for planting out in beds. Mimulus for beds should be planted in them in the spring, and they make a fine show for a time, but are very poor after a month or two of bright weather. They like a slightly shady situation and moist soil.

ORNAMENTAL GRASSES (*E. B.*).—Some hints on this subject will appear shortly.

LAYING OUT A PLEASURE GROUND (*An Irish Subscriber*).—We quite approve of your planting Rhododendrons against the wall of the proposed pleasure ground. At Raith, near Kirkcaldy, in Scotland, a wall is thus covered with the common Rhododendron right to its top, and the border in front with the very best kinds, as reared and grafted by the late Mr. Crockett. It gave a noble background to the flower garden. When this border is decided on you will still have 88 by so much less than 106 feet for beds on lawn. We would rather you would devise a plan for yourself, or send one for us to amend or criticise, which we would gladly do, as well as the style of planting; but were we to furnish plans for every similar place where such plans are required, we could do nothing else. We will criticise any plan, but we cannot do more. The slope of the ground will be an advantage when the beds are looked at from either side. Something of the simple plan given at p. 113 of last volume might suit. Unless the plan is artistic, like that at Trentham, or Linton, the simpler it is the easier will it be to plant and manage.

Roses (*A Six-years Subscriber*).—Hybrid Perpetuals—Madame Furtado, Senator Vaise, John Hopper, Pauline Lanzeur, Baronne Prevost, Général Jacqueminot, Géant des Batailles, Lord Raglan, Louise Odier, Jules Marquette, Comte de Nanteuil, and Caroline de Sansal. Hybrid Chinas—Charles Lawson, Chénédole. Hybrid Bourbon—Coupe d'Hébé, Souvenir de la Malmaison. Tea—Gloire de Dijon, Adam. Noisettes—Lamarque, Triomphe de Rennes.

MILDEWED HAMBURGH GRAPES (*A Constant Reader, Hammersmith*).—The berries had been so rubbed by shaking in the course of carriage that we are not certain whether they were mildewed. We incline, however, to think that they were; and if these Grapes were under our care we should fill a soup-plate with flowers of sulphur, roll each bunch in the sulphur, and rub each sulphured berry between the finger and thumb, leave the sulphur on for a week, and then syringe it off. We have seen Grapes thus cured that were severely mildewed.

MELONS (*C. P.*).—I have not found it necessary to cover with mats after shutting up the frames. With a moist atmosphere and no artificial heat, Melons will rarely be injured if shut up at the hours named. Of course much depends on the weather. If the day be very bright and hot, air may be required for an hour or two longer, and in cloudy weather the frames will need closing earlier. No special time can be given for opening and closing Melon-frames, the times mentioned relating to general rather than to special cases. With ordinary weather, however, the frames may be closed at the hours named, and no covering of mats is needed; for if any fear be entertained of the sun being too powerful air should be left on some time longer. To make all safe, however, the lights may be covered with mats for an hour, to be then removed. The mats should not, upon any consideration, be left on all night; but the glass must be exposed from May to September, or the plants will be deprived of many hours' light and sun heat.—G.A.

MUSHROOMS (*An Amateur of Six Months' Experience*).—It matters not whether the Mushroom-bed be in light or darkness. If in light the Mushrooms will be a little browner in appearance, if in darkness they come paler in colour. We think you will find all you want at pages 447 and 448 of the last volume, No. 169. If you wanted more definite information, and stated your means and materials, we would advise you more fully. With your experience we would advise you to delay making your bed for a month, unless it were a very shallow one. If you now make a bed of any size, unless in a cool cellar, you will be apt to have too much heat, as the heat of the atmosphere just now is too much for them.

COVERING A VINE-BORDER—AZALEA-BUDS NOT EXPANDING (*A. B.*).—We would cover the border with fern or litter by the end of September to keep in the summer heat. Very likely your Azaleas were dry on the surface of the ball. The plants would be benefited by an out-of-door position in September if the vineeries are densely shaded; if pretty well for light they may as well remain in the viney.

RIpening SECOND CROP OF FIGS (*J. G.*).—Your Fig trees planted out in a cool orchard-house and showing a fresh crop of young Figs—say in the beginning of July, will not ripen there unless the autumn is very clear and warm, and you shut up the house early in the afternoon. It will be of no use keeping such fruit over the winter, as most likely if the frost did not destroy them they would drop in the spring. By the end of September you will see; and then if there is no hope of ripening, you can cut off all the fruit that is larger than a good-sized Marrowfat Pea, and let the plants rest in winter by keeping them rather dry at the roots.

BEDDING GERANIUMS—SHADING CONSERVATORI (*Ignoramus*).—We could hardly decide there are so many. Of Scarlets, old ones, we would prefer Tom Thumb, Brilliant, Punch, and Excellence; for Rose Pinks, Shrubland Rose and Rubens; Pinks, Christine. Of Nosegays, none equals Stella as a dark scarlet. Driers such as painters use make capital shading for a conservatory. A quart of milk, an ounce of flour, and an ounce of whiting make also a nice shading. Half an ounce of soda or less to a gallon of water will do for making water soft. Full exposure to the sun for a day is better still. We prefer the quassia without the soft soap.

ARATCARIA IMERICANA FORMING CONES (*A Subscriber*).—It has done so at Binton and other places.

CONSTRUCTING A VINEY (*A Three-years Subscriber*).—Your house will be a hipped-roofed lean-to—that is, width 16 feet, back wall 15 feet, front and end walls 3 feet, height of front glass some 6 feet, front sloping glass to join a short hip from the back wall, the ridge from both 17 feet from the floor, length 45 feet. Now, first, your plan will no doubt answer. The main thing for Vines will be to secure drainage. Then for 45 or 50 feet in length, if you propose one end for a greenhouse and the other for a viney, it would be desirable to have a division with the power to heat one or the other separately or conjointly. This would even be advisable if you wished to have early and late Grapes. In fact, you might force one part and have late Grapes in the greenhouse part. Every place for Grapes we have is filled with plants, except when the Grapes are ripe, when the houses are kept airy and dry. The heating stove would be best placed in the middle. If economy were an object we would have a fixed roof, and give top air by the hipped-roof at back. Anything else you particularly want we will be glad to advise upon.

COMPOST FOR ROSES (*Jules Margolin*).—You will do well to mix lime with ditch-parings. It should be turned and mixed with black dung and then used. Brick refuse should be laid thickly over the surface, and kept well watered, and then, like burnt field-ashes, it will keep the ground moist. Lime is simply a re-agent, and not a manure. Chalk is an alternative, also, and not a manure. Lime and chalk are best suited to clay lands. Half-inch bones are good for Roses and Strawberries in light lands. So, also, is nitro-phosphate.—W. F. RADCLIFFE.

NAMES OF GRAPE (*P. M.*).—Your Grape is the Hubsee, an Indian variety.

NAMES OF PLANTS (*W. H. M., Kilkee*).—Aster tripolium. (*Viator*).—Spiraea arizeloides, Sm. The Holly is apparently the var. platyphylla. (*S. A. P.*).—1, Lobelia erinus, var. grandiflora; 2, Nepeta nepetella, L.; 3, Artemisia abrotanum, L.; 4, Potentilla atrosanguinea, Lodd.; 5, Zephyranthes, Schne. (*Lex.*).—The specimen sent is not sufficient to enable us to do more than guess that your plant is a species of Kleinia. (*M. M.*).—Comptonia asplenifolia. (*Glasgow Subscriber*).—Gymnogramma achryso-phyllea, a variable plant.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

JOTTINGS.

Did you ever attend a popular gathering at an Agricultural Meeting—one of those that are peripatetic, go from town to town within the limits of the county, and of which the presence is so beneficial that enterprising towns buy their

favours? Fancy the quiet little town of four or five thousand inhabitants suddenly exposed to the irruption of thirty thousand people! I could name many that I have visited on such occasions, and I like them. Often there is but one real street, the High Street, almost beginning before you get to the town, and ending beyond it. I like the irregularity of it—the dear old church standing on the highest spot in the town, with its venerable square-turretted tower; its almost obsolete sundial on its wall; its grotesque corbels; its old porch, inside which two fat-faced angels have watched those who entered for centuries; its green moss-covered tombstones telling the tale of past and passing generations. Yet it is not indifferent; the glorious flag of old England flies from the belfry, and the bells ring a merry peal all day. There are the old houses with pointed gables, latticed windows, and projecting upper stories; the two red brick houses, one belonging to the doctor, the other to the lawyer (why do these professions always choose comparatively modern and red brick houses?); the old inn, probably the George, the Angel, or the White Hart, venerable inside from its old dark oak wainscots, its wide staircase, its long corridors, and its square comfortable rooms; the new Railway Hotel raising its head above its predecessor, and boasting of its marble and looking-glasses; and the High Street in question—good, wide, comfortable street—you might put Regent Street in the middle of it, and leave Lombard Street on each side—in space only, be it understood. The shops lie many feet back from the road and rise from the gutter that carries off the rain. Many have trees in front. Long blinds protect from sun. On these holiday occasions everything puts on its best. There is the head haberdasher, look at his display, and see the number of empty packages he has placed in front to show the extent of his importations. The clothier has baited his trap for the sort of men that will come in charge of stock or on a holiday. The baits used to be smock-frocks and leather leggings, but now they are indescribable hats and caps, fancy neckties, and cheap jewellery, especially watch chains. Why, even the butcher's shop looks attractive. The trees in front keep off the sun, it is scrupulously clean, all the outer part is fresh painted, the back of the shop is thrown open, disclosing a garden, the leaves and boughs gently wave, suggesting a refreshing breeze; the very dead meat looks comfortable.

The neighbouring pleasure grounds and copses have been laid under contribution. During the night waggons have come rumbling in, the spade and pickaxe have been at work during the darkness, and the morning finds an avenue of fir, larch, and beech, huge limbs of which have been put in the ground. Flags of every colour, nation, and society wave in all directions. Garlands and devices attest the taste and the industry of the good wives and daughters (I like the term better than ladies, because if they are one they will be the other), of the place. It is the day of days in the history of the town—not only an Agricultural Meeting, but the Horticultural Show, and the band of the 200th Regiment. Ordinarily the tradesmen of these quiet country towns are men to be envied, compared with the hurried anxious-looking men in London; but for some days before the show and for some days after they are at work night and day. Being an idle man, I have had leisure to watch these things. I was much amused a few years since when dining with some members of the committee the evening before the show. The question was asked who should go to the station to meet the military band. I hardly know why, but no one cared to go. It is a common case for a committee collectively to be all that is energetic, but not a member of it has, or fancies he has, sufficient energy to act alone. It was so in this instance, and the difficulty became so great that they drew lots. The lot fell on the most diffident of all. Like a prudent man, finding it inevitable, he began to make inquiry, and prepare himself; and having ascertained that the band-master of a crack regiment was a superior man, he went home for a night's rest to fit himself for the ordeal of the morrow. The station was nearly a mile from the town, and the time for meeting the band was eleven. I determined to be there. The committee-man was on the platform fidgetting nervously about. The bell rang, and his excitement increased. As the train drew up, men in caps with variegated bands, clad in a white uniform with green facings, could be seen looking out of the windows. I saw my man scan every

one who got out; he was about to address several, at last, like most nervous and unready men, he made the only mistake he could make—he asked the master to show him the master. There is no mistake in addressing the sergeant as the colonel, but *vice versa*. This was a *contretemps*, but he got over it, or, rather, the subject of it saved him with much tact. The band formed outside the station, and the committee-man walked at the head by the side of the master. Then the transformation began; he was wrong, and changed step; he became more upright; he waived his walking-stick like a *bâton*, beat the measure, and stepped to time; he attached himself to the band all day, and headed it when it returned to the station in the evening.

These gatherings are essentially merry ones. The stream from the station to the principal inns and the show-yard, the country roads full of carriages, from the four-horse drag to the donkey-cart, the pedestrians dusty and travel-stained, all show gay costumes and smiling faces. What a change in costume and appearance! Beards, moustaches, and strange head-gears are the rule! What would be thought of the old heavy beaver of the gentlemen and yeomen, and the dogskin hat of the labourer now, in the days of wideawakes, deerstalkers, &c., decorated with a flower or a feather? But folk are all merry and good-tempered, and they are pressing to the show-yard. The ladies go off direct to the poultry. It is in a long tent, and that is crowded all day; thence they go to the flowers, then the fruit, and come to their rest where the band of the 200th Regt. is performing. The conductor understands his company, his grand music at the beginning was intended for the sedate world, but as the younger portion come to an anchor round him he glides off into rapid waltz, polkas, and quadrilles. It tells; every foot is beating time, and many a heart wishing for a dance. The male portion of the visitors are soon surrounding horses, oxen, sheep, and pigs. Things would be too smooth if there was not a little uproar. There is a stout man standing by a pen of pigs, and he declares he will have justice if it is to be had for money; and he does not hesitate to say the judges are fools, or something worse, to dispute the age he has put on his pigs. He won't show any more, nor will a good many others; no, nor he won't subscribe, not he.

There is a dinner at the Montmorency Arms at four. All the county members will be there, and all the nobility and gentry of the neighbourhood, and thither the throng wends. Step into the hotel with me. Every room has three or four parties in it. A dozen wait to take advantage of anyone who moves from a table. Bells ring continually, but attendants are few and far between. The extra men hired for the occasion take things coolly, but the regular servants fret, fume, and tear about, and wish the day over at two in the afternoon. Rows of men carrying trays pass in procession from the inn to the Town Hall, where the dinner is held. Fresh salads, pale pastry, drooping jellies, tempt the gaping children. Fore-quarters of lamb, ribs of beef, chickens that show a society for improving the breed of poultry has work to do, hams, and fillets of veal, pass in quick succession. At four o'clock a light cart draws up to the door, and is soon filled with savoury haunches from the parks of the neighbouring gentry. It spins across the road and returns for another burden; and then the business of the dinner begins. The town then takes another character. The shops shut up; the real inhabitants turn out; those who have far to go home, or who dislike a crowd and bother, order their carriages; those who go by train flock to the station. There is an extra staff for the day, but it is useless on the platform. The carriages are forcibly taken possession of, and remonstrance is useless. We once met a superintendent from London on such an occasion who was well up to his work. His carriages were crowded, and he was set at nought. When he said it was the wrong train he was laughed at. But he was a man of resource. He entered his office, and two porters issued from it a moment afterwards, walked the length of the train, crying, "This train for Tring and London only." The thing was well done. The engine gave the premonitory scream, the guard asked if all was right, and had the whistle to his lips, but not in his mouth, when all the carriage doors opened, and disgorged the now frightened though lately bouncy passengers, who, belonging to the many third-class stations in the neighbour-

hood, did not relish the idea of going there *via* London, and paying the difference of the excursion ticket.

(To be continued.)

THE AGRICULTURAL HALL POULTRY SHOW AND THE POULTRY CLUB.

In reply to your correspondent "AN EXHIBITOR," I beg to state that I have neither time nor inclination to enter into the paper war which he appears to wish, particularly as facts appear to have so little impression upon him. To him as to all other of your correspondents I say, Communicate directly, and they shall have all the information I can give. With me the matter ends here.—E. TUDMAN, *an Hon. Sec. to the Poultry Club, Ash Grove, Whitchurch, Salop.*

HOWEVER true may be the remarks of your correspondent "AN EXHIBITOR," I am very certain and at the same time very glad that he is not the delegate, or, as he would say, "the *locum tenens*," of poultry exhibitors generally.

He expresses himself as being "truly amazed" that any one should have the "hardihood" to deny that the appointment of Mr. Hewitt as judge at the forthcoming Islington Show had taken place. I again state that if he had read all the correspondence between you and Mr. Tudman he would have seen that "no such appointment has taken place;" and if he means to doubt the word of the Honorary Secretary of the Poultry Club, who is surely a person qualified to know what the Club is doing, I am the person to be "amazed," and he is the one that possesses the "hardihood." That which your correspondent calls a "palpable fact" is not a fact at all.

In reference to the rules of the Club, this "EXHIBITOR," who appears not to quite understand what he is writing about, wishes to know, "How comes it that they have not been acted on?" In answer to this, the rules are not yet fully compiled, and are at present undergoing revision, which is proved by the limited issue of the copies. I in turn want to know how anything can be said to fail before it has been tried.

In conclusion, allow me to beg of "AN EXHIBITOR" not to write in future upon a subject till he fully comprehends it.—A POULTRY FANCIER.

LEICESTERSHIRE AND WALTHAM POULTRY EXHIBITION.

THIS Exhibition of poultry forms a part of the stock shown at the annual agricultural meeting of this Society, which this year took place at Market Harborough, the object of the promoters (judging by the prize schedule), being more to encourage useful poultry than those breeds which are rather Fashion's favourites. Great care is taken of the poultry whilst on exhibition, and with the well-known Turner's Sheffield pens, the Show was a really well-ordered one. True it is, the number of pens shown were fewer than customary, it being now the midst of the moulting time, as it is certain that fowls are moulting some six weeks earlier than last season—a feature that will tell much in favour of the late shows. Some of the chickens shown were very early birds, as forward as any we have seen this year, and in excellent feather; but the adults, as a rule, were in a state of semi-nudity.

It will be well just to remind our readers, that in *Pigeons*, however good individually, birds of directly opposed colours cannot hope for success exhibited as pairs, the matching of feather being as indispensable in *Pigeons* as in poultry.

We were glad to see the Judges marked their disapproval of the quite too common plan now-a-days, of exhibiting two or more ganders in a pen, devoted according to rule to a male and two females. One pen of three ganders, and another of two ganders and a Goose, though the best by far as to size and feather, were most properly disqualified.

The weather being exceedingly fine, without great heat, the number of visitors was most satisfactory, and the Show may be deemed a success.

DORKING.—First, B. Everard, Bardon Hill House. Second, — Sheffield, Geddington Lodge. Chickens.—First, B. Everard. Second, T. Burnaby, Upper Lodge, Pipewell.

SPANISH.—First, M. Brown, Ab Kettleby. Second, B. Everard, Bardon Hill House. Chickens.—First, withheld, there being no competition. Second, B. Everard.

COCHIN-CHINA (Any colour).—First, A. Guy, Eaton, Grantham. Second, J. Buckley, Desford. Chickens.—First, J. B. Hanbury, Clipston House. Second, Capt. T. Wetherall, Loddington. Commanded, A. Guy.

COCHIN-CHINA (White).—First, M. Brown, Ab Kettleby. Second, T. Sheppard, Humberstone. Chickens.—First, T. Sheppard. Second, G. Sheen, Leicester.

GAME (Black-breasted and other Reds).—Prize, Capt. T. Wetherall, Loddington. Highly Commended, M. Brown, Ab Kettleby. Chickens.—Prize, B. Everard, Bardon Hill House. Highly Commended, Sir W. de C. Brooke, Bart., Geddington Grange.

GAME (White, Piles or any other colour).—Prize, B. Everard, Bardon Hill House. Highly Commended, H. W. White, Home Farm, Great Crosby. Chickens.—Prize, B. Everard. Commanded, A. Guy, Eaton.

HAMBURGH (Of any colour).—Prize, R. E. Duckering, Northorpe. Chickens.—Prize, H. E. Emberlin, Humberstone.

SINGLE COCKS.

DORKING.—Prize, B. Everard, Bardon Hill House.

SPANISH.—Prize, M. Brown, Ab Kettleby.

COCHIN-CHINA (White).—Prize, F. W. Montgomery, Gadesby.

HAMBURGH.—Prize and Commanded, J. Buckley, Desford.

BANTAMS (Clean-legged).—First, Capt. T. Wetherall, Loddington. Second, H. E. Emberlin, Humberstone.

GAME BANTAMS (Black-breasted and other Reds).—First, Capt. T. Wetherall, Loddington. Second, A. Guy, Eaton, Grantham.

ANY OTHER VARIETY EXCEPT GAME.—First, A. Guy. Second, W. Chamberlain, Desford. Cock.—Prize, G. Sheen, Leicester.

DUCKS (Aylesbury).—First, H. E. Emberlin, Humberstone. Second, M. Brown, Ab Kettleby. Highly Commended, H. E. Emberlin.

DUCKS (Rouen).—First, J. Sheppard, Geddington Grange. Second, T. Burnaby, Upper Lodge, Pipewell.

TURKEYS (Black).—First, J. Johnson, Brampton. Second, J. E. Bennett, Husbands Bosworth Grange.

TURKEYS (Any other variety).—First, A. Guy, Grantham. Second, J. Johnson, Brampton.

GESE.—Prize, W. Kirk, Wymondham.

PIGEONS.—Tumblers.—First, F. W. Montgomery, Gadesby. Second, Right Hon. Viscount Ingestre. Pouters.—Prize, H. E. Emberlin, Humberstone. Runts.—First, H. E. Emberlin. Second, J. Buck, Leicester.

Jacobines.—Prize, H. E. Emberlin. Fantails.—Prize, W. Draycott, Humberstone.

RABBITES (For the heaviest weight).—Prize, W. Chamberlain, Desford.

ANY OTHER KIND.—Prize, W. Chamberlain. Highly Commended, F. W. Montgomery, Gadesby.

W. Dolby, Esq., of Rotherfield, and Edward Hewitt, Esq., of Sparkbrook, Birmingham, officiated as Judges.

SUCCESSFUL POULTRY-KEEPING.

As it is more pleasant to hear of success than failure, I am tempted to send you my experience in chicken-rearing this season; and think even the successful poultry-keeper, page 57, will acknowledge himself beaten. I shall be glad to hear if any one has been more fortunate than myself.

COCHIN.—Feb. 11th, 5 hatched, 3 reared; Feb. 22nd, 4 hatched, 4 reared; April 1st, 4 hatched, 3 reared; April 14th, 7 hatched, 7 reared; May 1st, 7 hatched, 7 reared; May 2nd, 8 hatched, 8 reared; May 8th, 13 hatched, 13 reared. Total, 48 hatched, 45 reared.

HAMBURGH.—Feb. 11th, 6 hatched, 6 reared; April 20th, 12 hatched, 12 reared. Total, 18 hatched, 18 reared.

The first two lots consist of two cockerels and five pullets, and average 4 lbs. 15 ozs. each. The pullets all commenced laying during the first week in July.—K.

BUDE HAVEN & STRATTON HORTICULTURAL AND POULTRY SHOW.

The eighth Exhibition of this Society was held on Friday, July 29th, in two spacious tents, in convenient grounds immediately adjoining the picturesque little church of Bude, commanding fine views of the Haven and the surrounding romantic scenery for which this favourite little watering place is famed. The Show lasts but one day, so that the birds are not fatigued by too long confinement in the poultry pens. One great disadvantage under which the Society labours is the fact that the nearest railway station is fully twenty-six miles distant, so that whatever birds are sent from long distances have this tedious journey of twenty-six miles to perform by coach before reaching their destination. This necessarily tends to deter amateurs who reside in other counties from sending their birds. There is, however, some talk of a railway being constructed to connect Bude-Haven with the North-Devon line, and if this scheme be carried out, a vast improvement will no doubt be visible there in other things besides poultry.

Considering the drawbacks under which they labour, the Committee succeeded in drawing together the comparatively large number of nearly two hundred pens; and though, as might be expected from the secluded character of the locality, there were several pens showing defects in the matching of combs and legs, yet the great bulk of the birds proved by their appearance and condition that the lessons of former years have not been lost upon their owners, and that very great pains have been taken in most instances to win prizes by intrinsic merit alone. Capt. Davey, an extensive ship-owner residing at Bude, kindly undertook the charge and care of all specimens from a distance, and we are bound to state that the greatest care and attention was bestowed upon the birds while in the pens as to feeding, water, &c., and we have no doubt that the owners received them back from the Show in as good condition as when they sent them off.

Subjoined is a list of the prizes awarded:—

DORKINGS (Coloured).—First, Rev. G. De C. Guille. Second, Rev. A. C. Thynne. Third, J. Brock. Fourth, E. Hockin. *Chickens*.—First, Rev. J. R. Whyte. Second, Rev. G. De C. Guille.
 DORKINGS (White).—First, W. Pickard. Second, Miss Maskell.
 EXTRA PRIZE (Given by the Rev. George De C. Guille).—Prize, Rev. J. R. Whyte (Dorking Cock).
 SPANISH.—First, R. Hoskin. Second, G. Slumen. *Chickens*.—First, R. Hoskin. Second, Rev. S. N. Kingdon.
 MANORCAS.—Prize, W. Shearm.
 GAME.—First, A. West. Second, H. Parsons. *Chickens*.—First and Second, Rev. H. M. Bazeley.
 COCHIN-CHINA.—First and Second, A. Trewin.
 MALAYS.—First and Second, H. Darch.
 CORNISH (Black).—First, — Galsworthy. Second, D. Maynard.
 HAMBURGS (Golden-pencilled).—First, Mrs. Kingdon. Second, J. F. Delmar.
 HAMBURGS (Golden-spangled).—Prize, J. L. Smith.
 HAMBURGS (Silver-pencilled).—First, — Ham. Second, J. Walter.
 HAMBURGS (Silver-spangled).—First and Second, M. L. Lucas.
 POLANDS (Golden-spangled).—First, F. Gloyne. Second, J. Short.
 POLANDS (Black W. T.).—First and Second, W. L. Trewin.
 BARNDOE.—First, W. Venner. Second, H. Francis. Fourth, W. J. L. Lyle. Third withheld.
 BANTAMS (Gold-laced).—First, Rev. H. M. Bazeley.
 BANTAMS (White).—First, Rev. G. De Guille. Second, W. Allin.
 BANTAMS (Black, &c.).—First, W. A. Deane. Second, W. Broome.
 GUINEA FOWLS.—First, W. M. L. Lucas. Second, Rev. G. De C. Guille.
 DUCKS (Aylesbury).—First, J. Bines. Second, Rev. R. R. Wright. *Ducklings*.—First, Rev. T. S. Carnes. Second, J. Jewell.
 DUCKS (Common).—First, Rev. G. De C. Guille. Second, T. Trewin. *Ducklings*.—First, Master T. Symons. Second, N. Pethick.
 TURKEYS.—First, G. Risdon. Second, Rev. A. C. Thynne.
 GESE.—First, W. Brock. Second, Rev. G. De C. Guille.
 PIGEONS.—*Carrivers*.—Prize, Miss Lyne. *Barbs*.—Prize, Miss Lyne. *Pouters*.—Prize, Miss Bray. *Fantails*.—Prize, Miss Lyne. *Jacobsins*.—Prize, Miss Lyne. *Trumpeters*.—Prize, Miss Lyne. *Tumblers*.—Prize, J. M. Braund. *Blue Rock*.—Prize, — Larke. *Common Pigeons*.—Prize, Miss Lyne.
 RABBITS (Lop-eared).—First, H. Gist. Second, H. Pooley. *Common*.—First, Miss Burton. Second, J. Brimacombe.
 EXTRA PRIZE (Given by William Maskell, Esq.).—Prize, H. Darch.
 EXTRA PRIZE (Given by the Committee).—Prize, T. Wood.

The Judges were M. C. Ballance, Esq., of Taunton, Somerset; and Mr. Leworthy, of Barnstaple, Devon; and their awards appeared to give entire satisfaction.

DRIFFIELD AGRICULTURAL SOCIETY'S POULTRY SHOW.

THIS was held on the 30th of July. The following were the awards:—

DORKINGS.—First, M. Hunter, Green Hamerton. Second, Col. Loftus Sunderlandwick. *Chickens*.—Prize, W. Watson, Bishop Burton.
 SPANISH.—First, W. Cannan, Bradford. Second, W. Hunter, Green Hamerton. *Chickens*.—Prize W. Cannan.
 GAME (Black-breasted and other Reds).—First, H. Adams, Beverley. Second, W. Boyes, Beverley. *Chickens*.—Prize, H. Adams.
 GAME (Duckwing and other Greys).—First and Second, H. Adams, Beverley. *Chickens*.—Prize, R. Wool, Lockington.
 GAME (Any other variety).—First and Second, H. Adams, Beverley. *Chickens*.—Prize, H. Adams.
 COCHIN-CHINA.—First, T. H. Barker, Hovingham. Second, T. C. Trotter, Sutton. *Chickens*.—Prize, S. Robson, Brotherton.
 POLANDS.—First, W. Cannan, Bradford. Second, R. Loft, Woodmansey. HAMBURGS (Golden-spangled).—First, W. Cannan, Bradford. Second, S. Camping, Cottingham. *Chickens*.—Prize, W. Cannan.
 HAMBURGS (Silver-spangled).—First, W. Cannan, Bradford. Second, S. Camping, Cottingham. *Chickens*.—Prize, G. Featherstone, Cottingham. HAMBURGS (Golden-pencilled).—First, W. Cannan, Bradford. Second, J. R. Jessop, Hull. *Chickens*.—Prize, W. Cannan.
 HAMBURGS (Silver-pencilled).—First, W. Cannan, Bradford. Second, G. Holmes, Driffield. *Chickens*.—Prize, W. Cannan.
 ANY OTHER PURE OR DISTINCT BREED NOT PREVIOUSLY CLASSED.—First, W. Cannan, Bradford. Second, R. Loft, Woodmansey. *Chickens*.—Prize, R. Gowden, Bridlington.
 FARMYARD CROSS.—First, H. Pinkney, Frodingham. Second, D. Dalby, Cottingham.

BANTAMS (Black and White).—First, W. Cannan, Bradford (Black). Second, G. Mosey, Skerne (Black).
 BANTAMS (Any other variety).—First, J. R. Jessop, Hull (Gold-laced). Second, T. Holmes, Driffield (Game).

SINGLE COCKS.

DORKING.—Prize, M. J. Grimston.
 SPANISH.—Prize, R. Tate, Leeds.
 GAME (Black-breasted and other Reds).—Prize, H. Adams, Beverley.
 GAME (Duckwing and other Greys).—Prize, H. Adams, Beverley.
 GAME (Any other variety).—Prize, H. Adams, Beverley.
 COCHIN-CHINA.—Prize, T. C. Trotter, Sutton.
 POLANDS.—Prize, T. C. Trotter, Sutton.
 HAMBURGS (Golden-spangled).—Prize, W. Cannan, Bradford.
 HAMBURGS (Silver-spangled).—Prize, W. Cannan, Bradford.
 HAMBURGS (Golden-pencilled).—Prize, R. Mosey, Malton.
 HAMBURGS (Silver-pencilled).—Prize, T. C. Trotter, Sutton, Hull.
 ANY OTHER PURE OR DISTINCT BREED NOT PREVIOUSLY CLASSED.—Prize, Col. Loftus, Sunderlandwick.
 FARMYARD CROSS.—Prize, G. Robinson, Hornsey.
 BANTAMS (Black and White).—Prize, W. Cannan, Bradford (White).
 BANTAMS (Any other variety).—Prize, T. Holmes, Driffield.

GESE.—First, Mrs. O. A. Young, Driffield. Second, Mrs. Nicholson, Lower Driffield. *Goslings*.—Prize, Mrs. Robinson, Swaythorpe.
 TURKEYS.—First, W. Cannan, Bradford. Second, Mrs. T. Dawson. *Poults*.—Prize, Mrs. T. Dawson.

GUINEA FOWL.—Prize, Mrs. O. A. Young, Driffield.
 DUCKS (Aylesbury).—First and Second, W. H. Young, Driffield. *Ducklings*.—Mrs. O. A. Young, Driffield.
 DUCKS (Rouen).—First, T. H. Barker, Hovingham. Second, J. Braim, Pickering. *Ducklings*.—Prize, J. Braim, Pickering.
 DUCKS (Any other variety).—First, J. Braim, Pickering. Second, J. R. Jessop, Hull (East Indian). *Ducklings*.—Prize, J. R. Jessop (Wild).
 PIGEONS.—*Croppers*.—Prize, S. Robson, Brotherton. *Carriers*.—Prize, B. Leason, Driffield. *Trumpeters*.—Prize, J. Key, Beverley. *Jacobins*.—Prize, T. Ellington, Woodmansey. *Fantails*.—Prize, J. R. Jessop, Hull. *Tumblers*.—Prize, Miss R. Leason, Driffield. *Barbs*.—Prize, F. Key, Beverley. *Nuns*.—Prize, B. Leason, Driffield. *Any other Variety*.—Prize, S. Robson, Brotherton (Runts).

RABBITS (Best pair of any breed).—First, W. Holmes, Driffield. Second, G. R. Young, Driffield.

EXTRA PRIZES.

BANTAM CHICKENS.—Prize, O. A. Young, Driffield.
 PIGEONS.—Prize, J. R. Jessop, Hull (Turbits).
 RABBITS.—Prize, C. H. White, Driffield.

The Judges were B. Baxter, Esq., Skipton; and S. Bird, Esq., Shipley.

HASLINGDEN POULTRY SHOW.

THIS was held on the 28th ult., and we are well pleased to hear that it was a great success. The following were the awards:—

GAME (Any colour).—First, C. W. Brierley, Middleton. Second, J. Turner, Radcliffe.

DORKING (Any colour).—Prize, G. Petter, Fallowfield, near Manchester.

COCHIN-CHINA (Any colour).—First, T. Stretch, Ormskirk. Second, F. M. Hindle, Haslingden.

SPANISH (Black).—First, R. J. Wood, Lower Crumpsall. Second, J. Seddall, Halifax.

BRAHMA POOTRA (Any colour).—First, H. Lacy, Hebden Bridge. Second, J. Hinton, Hinton, near Bath.

HAMBURG (Golden-pencilled).—First and Second, S. Smith, Halifax.

HAMBURG (Silver-pencilled).—First, C. Moore, Poulton-le-Fylde. Second, A. Nicholson, Sheffield.

HAMBURG (Golden-spangled).—First, J. Andrew, Ashton-under-Lyne. Second, C. Cowburn, Leeds.

HAMBURG (Silver-spangled).—First, J. Andrew, Ashton-under-Lyne. Second, M. Isherwood, Radcliffe.

ANY OTHER VARIETY.—First, H. Carter, Holmfirth. Second, G. Dawson, Rawtenstall.

BANTAMS (Game).—First, J. Munn, Newchurch. Second, R. M. Stark, Hull.

BANTAMS (Any other variety).—First, C. Walker, Halifax. Second, G. Ormerod, Accrington.

SINGLE COCKS.

GAME (Any age or colour).—First, C. W. Brierley, Middleton. Second, T. Dyson, Halifax.

BANTAM (Game).—First, M. Turner, Preston. Second, T. Kenyon, Blackburn.

TURKEYS.—First, C. W. Brierley, Middleton. Second, E. Leach, Rochdale.

GESE.—First, T. Houlker, Blackburn. Second, S. S. Stott, Flaxmoss, near Haslingden.

DUCKS (Aylesbury).—First, E. Leach, Rochdale. Second, F. M. Hindle, Haslingden.

DUCKS (Rouen).—First and Second, E. Leach, Rochdale.

DUCKS (Any other variety).—Prize, T. Hall, Haslingden.

The Judges were Mr. E. Teebay, Fulwood, Preston; and Mr. T. Dodds, Watkinson Hall, Liverpool.

DUCK ASSUMING THE PLUMAGE OF THE DRAKE.

I BEG to add the following to the instances already given of fowls assuming the plumage of the male bird.

In 1858 I had a lot of Ducks, one of which commenced to

moult in the autumn, and by the following spring was arrayed entirely in the plumage of a drake. In the first-named year she laid, but when habited in drake's costume ceased doing so. She was killed for the table, but no eggs were discovered in the ovary.

This occurred in the province of Luxemburg, where I was then living. No one there had ever seen such a case, although several peasants had had hens which assumed the cock's plumage, and one had returned to the plumage of a hen the next year.—A. S.

CANKER IN PIGEONS.

In reply to Mr. Burton's inquiry, I am afraid his birds have become unhealthy from some cause which shows itself in the breaking-out about the mouth of the cankerous disease to which Pigeons are often liable. It may arise from various causes—too hot or stimulating a diet, as too much hemp-seed, or want of natural condiments; and it has been attributed to dirty water, drinking from tin vessels, drinking the water in which they have bathed, or from mice wetting among the corn.

I have found much good arise from removing the pus and thoroughly rubbing the place with caustic. I have also cured a case by rubbing salt into the part when the matter was removed. By all means let the Pigeons have a little salt. I do not think wheat alone good feeding for Pigeons; lentils, small beans, and buckwheat are a good change. I should be pleased to hear if the caustic or salt proves a cure. In using the caustic care must be taken to touch every part of the sore, or the matter will form again.—BERNARD P. BRENT.

SETTLING PIGEONS IN A NEW HOME,

AND LETTING THEM OUT FOR THE FIRST TIME.

THE letter of your correspondent, "J. I. D." in No. 175, suggests the desirability of a few passing remarks on settling or accustoming Pigeons to a new abode, and the care requisite in letting them out for the first time; for, as your correspondent remarks, he has "a crotchet that birds breed better if allowed to fly out." In this he is quite correct; and I may add that the Pigeons will be very much the healthier if they have their liberty, and will be enabled to pick up many little condiments, which all the care of the fancier is but indifferently able to supply. It is, therefore, always advisable to give the Pigeons their liberty when practicable, which in the great majority of cases it will be found to be, most Pigeons being able to fly sufficiently to keep out of danger; and although one or two may be lost from some cause or other owing to their being at large, yet I am convinced that many more die, or are lost, from being kept confined. I would not, however, advise any one suddenly to rush to the opposite extreme, and turn out all his Pigeons without some previous care and discrimination, because a Pigeon that has grown to maturity in confinement and suddenly finds itself at large, becomes bewildered, and gets into difficulties that a young bird would escape, owing to its natural instinct; whereas the older bird, being cramped in its intellect, as it were, is taken off its guard.

It may be as well to inquire what this instinct is. I think it will be admitted that many animals have the power to return home from distant places without any previous knowledge of the road. Few persons but can call to mind some account of cats, dogs, horses, and other animals returning home, when it seemed impossible for them to know anything of the road. I believe it is a faculty by which they have an intuitive perception of the right direction, and follow it by a natural impulse. This is, I consider, instinct, and not at all controlled by reason.

Among the wild Doves or Pigeons there is a difference in this instinct. Some are erratic or wandering in their ways. These are mostly arboreal in their habits, and, except for the purpose of nesting, have no settled home. Such Pigeons may be tamed, but cannot be domesticated, because if let out they stray away, and have no instinct to attach them to any spot. Such is the case with our largest Wood Pigeon, the Ring Dove; whereas the Rock Pigeon has a settled abode to which it always endeavours to return. If it strays

away in search of food, as soon as its hunger is satisfied it returns home by mere instinct as a natural act, without thought or concern. Thus the Rock Pigeon, though such a shy, wild bird, can be domesticated. See how the bee wanders in search of honey, winding and twisting, searching and hunting, from flower to flower, and when filled returning direct to the hive. Cats have been carried away to strange places in bags or covered baskets, and returned home many miles when let out. Many are the stories of dogs, horses, and bullocks returning home by some unexplained faculty. Domestic Pigeons are highly endowed with this power, and have always a desire to return home when at a distance from it. So strong is this propensity that man has been led to take advantage of it, and selecting strong or quick-flying breeds, has trained them to come home from very long distances, and thus to be the bearers of dispatches or news.

Having briefly considered this inherent faculty or instinct of Pigeons, there can be little wonder if an amateur buys a pair of Pigeons and lets them out without due precaution, that the birds will stray away, and probably be lost. A few words on the means to be adopted to lessen this impulse, and, if possible, to create a counter-attraction, is the object of my present letter.

Much difference will be found in the strength of this instinct in different individuals, as also in their powers of flight and consequent capability of following this impulse. A Pigeon that has been brought up in confinement is much in the state of a young bird that has for the first time left the nest, but, if anything, more stupid, and may require care not to frighten it from the roof, or immediate neighbourhood, until it has been in and out two or three times. A Pigeon that has previously been accustomed to have its liberty, and is for the first time let out at a new place, feels no bewilderment, but rather rejoices at its liberty, and sets off at once for its old home, its excursion being only curtailed by its powers of flight. It will depend very much on the counter-attraction set up in the new abode whether the Pigeon returns to it. It will at once be seen how very various is the amount of restraint required to attach a Pigeon to a new home.

My advice to any one when a new pair, or even a single bird, is purchased, is to keep them confined for at least three days in their new house, a fortnight would be safer; but, above all things, to see that the new comers have a private apartment—that is, a nest-place or two of their own, and that they have taken possession and have driven all others from it. This becomes their castle or retreat, and to it they return: if they go out and cannot find their old residence, they will try and return to this new possession. When a Pigeon, or a pair of new Pigeons have been out, and sought in vain for their old house, then, having found their way back to the nest place of their new home, there is but little fear of their leaving afterwards, unless at any time another Pigeon has beaten them from their retreat, when they may then roam in search of a new nest-place.

Ordinary tame Pigeons may be let out three days after they have taken possession. Better flying kinds should be kept in a fortnight. Such as have been accustomed to find their way home from the fields, or have been trained for homing, must be kept in for a longer time if their old home is not too far for them to reach easily, in which case they will have to be brought back two or three times ere they will stop. Sewing a few of the long wing-feathers together to prevent their flying too much at first, or, as some recommend, soaping their wings—an experiment I have never tried—may serve to keep them at home for a few days; but if once they return but little trouble will be experienced afterwards.—B. P. BRENT.

RABBIT-HUTCHES.

It may be of some interest to your readers who are rabbit-fanciers if I state my experience in keeping rabbits in hutches with sparred floors. I find they keep the rabbits cleaner and sweeter, and they thrive much better than when on close boarded floors. There is no effluvia from the hutches, and twice as many can be kept in the same space as when on close boarded floors. My hutches with open boards are

very seldom cleaned out, and the rabbits are much cleaner than those that are on the close boards, which are cleaned out daily. The boards are 2 inches wide and half an inch apart.—AN AMATEUR FANCIER.

RABBITS LOSING THEIR HAIR—EARS FALLING TO ONE SIDE.

IN answer to “J. I. D.” I have frequently had my rabbits rub the fur off their noses, which is owing to their troughs being too narrow, and upon giving them broader ones the fur soon grows again. As to the young rabbits’ ears, out of a whole litter which I had at the commencement of this year every one had both falling on one side. The best remedy is to take them out of the hutch every morning and smooth their ears in the proper position for a few minutes at a time, until you find them remain properly.

As “J. I. D.” says that he is a novice as a rabbit-fancier, I think that perhaps he would like to know that I always offer my rabbits water, and in this warm weather I find that they will leave their green food for it. When I first commenced keeping rabbits many fanciers whom I knew told me that it was useless giving them bran. The consequence was that I found the young ones deserted immediately they were born; so I gave them bran, and I have not lost a single one, and they are all in splendid condition. If any gentleman be desirous of seeing them I shall be happy to show them on application by letter to—J. S. BLACKETT, 7, Canonbury Lane, Islington.

PREPARATION OF WAX.

I HAVE failed hitherto in extracting the wax from the empty combs. Will you have the kindness to give directions on this branch of bee-keeping?—CAVENDISH.

[The following directions are copied from “Bee-keeping for the Many.” After draining and washing the combs, Mr. Payne says, “Put them in a clean boiler with some soft water; simmer over a clear fire until the combs are melted: pour a quart or so into a canvass-bag, wide at the top and tapering downwards, like a jelly-bag; hold this over a tub of cold water; the boiling liquor will immediately pass away, leaving the liquefied wax and dross in the bag; have ready a piece of smooth board of such a length that one end may rest at the bottom of the tub and the other end at its top; upon this inclined plane lay your reeking bag, but not so as to touch the cold water; then, by compressing the bag with any convenient roller, the wax will ooze through and run down the board into the cold water, on the surface of which it will set in thin flakes; empty the dross out of the bag and replenish it with the boiling wax, and proceed as before until all has been pressed. When finished collect the wax from the surface of the cold water, put into a clean saucepan with very little water, melt it carefully over a slow fire, skim off the dross as it rises, then pour it into moulds or shapes, and place them where they will cool slowly. The wax may be rendered still more pure by a second melting and moulding.” The above is the process we have hitherto adopted, with this exception, that we placed the combs in a covered vessel which we stand in a boiler of water, forming in this way a water bath on the principle of an ordinary glue-pot and obviating all risk of over-heating. The operation of straining boiling wax through a canvass bag is, however, so disagreeable and “messy,” if we may be allowed the word, that we intend having an apparatus made for the purpose on the plan recommended by the late Dr. Bevan, and which he thus describes in page 259 of the second edition of “The Honey Bee:”—“The kettle I use is in shape like a flowerpot; the strainer is of the same shape but only half the depth, and it drops into the larger kettle full halfway with an accurate fit. The bottom of this inner kettle is perforated all over with very fine holes, and has a couple of ring handles. The rough combs being placed in the large kettle, water is poured in till it rises nearly halfway up the inner kettle, and the whole is placed over a moderate fire. As the wax melts out of the crude mass it percolates through the strainer and floats upon the surface, tolerably free from impurity, from whence, when cool, it is taken off in a cake, for

being re-melted and still further depurated, which may be effected by the same apparatus, varying the use of it a little. The cake of wax just referred to is now put into the upper kettle, and water to the depth of a few inches into the lower; the wax is then slowly melted again, when it will drop through the strainer and swim on the surface of the water, the impurities falling to the bottom. Having been separated from the water and any still remaining impurities scraped off, the wax should be again re-melted with just water enough to avoid burning, and poured into the moulds, the latter having been previously rinsed with cold water to prevent the wax from adhering to them. The moulds should then be placed near the fire and covered over to let the wax cool gradually, or the cakes will be liable to crack. This last melting should be conducted over a *very gentle* fire—such as wood embers and the like, or the wax will suffer materially in colour, fragrance, and tenacity.”]

DEPRIVING STOCKS.

ONE thing I wish to know is, I have worked my eight hives on the depriving system, from six I have taken over 30 lbs. of honey each, and the bottom hives are full, may I take 10 or 12 lbs. from them during the present week?—J. N., Wands-worth.

[If yours are large-sized frame-hives we deem it rather advantageous than otherwise to remove the two side combs during winter, provided there be ample stores in the other combs. It is well when breeding is proceeding rapidly in the spring to fill up the vacancies thus made with empty or full combs according to the necessities of the case. Under any other circumstances than those above indicated we should say, “Leave well alone.”]

ROOKS AGAIN!

AND why not? Surely smaller subjects have a great deal written upon them. There are my good friends the apiarists of this Journal; what a small subject they have to write about, and yet they go on and on each week—writing about what?—A little gadfly-looking insect, that stings me, and makes honey which is so sweet that I abhor it. But, pray good bee-lover, despise me not, and be not angry with me. I do not understand your hobby, so know not the pleasure it affords you. After all, ignorance is the great foe to enjoyment. A man does not know and so he does not enjoy. To wit, there round my garden walks a high wrangler from Cambridge, who ascends, indeed, with ease the heights of mathematics, and sees much to love in them; but he saunters round my flowers, knowing nothing about them, and, therefore, he receives little or no pleasure from what to me are sources of infinite delight. For, as saith Words-worth—

“To me the meanest flower that blows can give
Thoughts that do often lie too deep for tears.”

Then, again, I have a visit from a wise florist who revels in my roses: he understands, and, therefore, loves and receives pleasure from them. But I presently point out my fowls to him, that noble-looking brave-faced but not cruel-eyed Game cock; those high-bred elegantly-shaped Game pullets, whose plumage, like the dress of a true gentlewoman, is so neat and yet so telling. My flower-loving friend has no eyes for the birds, he has no ears for such a subject as poultry, and merely observes—“Those birds of yours seem very slim and can’t have much worth eating on their bones.” Yes, ignorance is the greatest foe of all, mark my words, to enjoyment. So I say, Good readers learn, love to learn; and the more you learn, the more you get to understand everything in Nature, the more enjoyment you will have; you will possess “the harvest of an observant eye,” that richest of harvests.

I have been watching for some months my sable brothers, the rooks. Last May I watched them in a peculiar way—one eye shut, the other looking along a gun-barrel; but I endeavoured to kill them outright, using a full charge and taking aim at a vital part, the head killing them “as if I loved them,” slightly to alter old Izaak Walton.

Now I believe a rook has a conscience or something akin

to it, which I do not think any other bird has. I will give a proof of this. A pair of newly-wedded rooks are building their first nest, they have chosen the site, they have worked hard, and now in the joy of their hearts they go out together for a little relaxation, or, perchance, to some one of Nature's upholstery shops to get some last furnishing for their house. Clear out of sight, a pilfering rook comes, a thief who to save himself labour (Oh! the idle scamp!) begins to appropriate to his own use the materials of this nest. At it he goes, love of mischief makes him for this once industrious, and before the rightful owners return his work is over and he is sitting on a bough near by giving a few complacent caws in the sunshine, looking according to man's judgment as innocent as innocent can be. Young Mr. and Mrs. Rook are returning. On they come, the young husband eyeing fondly his wife, who will to-morrow be the happy guardian of her first egg—when, oh! the uncertainty of sub-lunary happiness! they see their nice new nest sorely damaged if not destroyed. Now what do they do? They at one glance know who is the offender, "That's he," say they; they seem to know him because his conscience or something akin to it makes him look guilty. "Conscience does make cowards of us all," rooks as well as men. At him they go, they buffet him and beat him while the poor conscience-stricken coward utters a peculiar scream and does not offer to fight—he has not the heart to fight, his conscience makes him powerless.

Then, again, about rooks. They walk, and with what dignity they walk! See a number of them on a grass field in the spring, how solemn and imposing is their gait! I have a theory that every bird that walks is possessed of inherent dignity, while a bird that hops has no dignity at all. Even in the extreme case of the smallest British bird that walks—viz., the wagtail, how charmingly he pit-pats along! If he would but abstain from wagging his tail, so belying his name, even that little fellow, tiny as he is, would not be wholly free from dignity; even as it is he looks very superior to the hopping sparrow beside him.

To speak of the wonderful knowledge of rooks is to speak of what everybody knows. Thus, how exactly they find the spot under which the grub lies, not by ear, so, at least, I think). In this respect they are unlike the blackbird, but the eye guides them, they notice the discolouration of the herbage. Indeed, I am inclined to believe that the eye is especially the rook's organ; one glance given, then they dig and dig, and lo! the grub is found. As the rooks come sailing leisurely over my garden on their way to and from the adjacent rookery, I often have a bit of fun with them. Thus, I see an old bird coming solemnly on, slowly, quietly flying as becomes a dignified rook of many years and much experience. When within shot I raise my walking-stick gun-wise to my shoulder, but I cause no commotion—old birds are not to be frightened with sticks; not the least change in his course does my friend make, one little pitying glance at me, and in bird language some remark of this kind:—"Only to think that the rector should take me for such a fool as to care about a walking-stick!" Then, presently, my gentleman comes back, and I now have my gun, and the moment I raise it, then instanter the rook changes his course, whirling away from me with another thought in his mind, which I may thus express—"Hollo, Mr. Rector, it's no nonsense this time I see; so good-bye to you and your horrid gun."

As to the plumage of rooks, what a fine, smooth, bright suit of black these my brethren always wear! I should not wonder if they chaff at and despise me when I have my old studying coat on, for it is with them "Sunday's best" all the year round.

I think Shakespeare somewhere says—

"The raven rook'd her on the chimney-top;"

and busy commentators tell us that the old verb "to rook," means "to squat down," but I differ from them. Doubtless, the bard of Avon meant that that ungainly fowl, the raven, tried to look like a rook, or to adopt his genteeler ways. The verb "to rook" does mean, we all know, "to rob," and, as I have shown, some rooks deserve the title of "robbers."

And now good-bye to rooks. Ye who possess a rookery, blessed people! shoot a good number of young ones each spring. Send presents of them to your friends, and "every

one is a friend to a giver of gifts." In regard to those you keep for your own share, order the cook to skin each one and take out his backbone, command her not to be too stingy either with beefsteak or hard-boiled eggs, and then cold or hot (I prefer the former), eat your pie, first saying a grateful grace.—WILTSHEE RECTOR.

PISCATORIAL.—Our attention was called this week to an eel, at what is called the "Loan Well," at Draffan, it being considered ninety years of age. Mr. Wm. Harvie, Mr. Wm. Pettigrew, and Mr. John Sommerville, vouch for the authenticity of this fact. Mr. Harvie, as the oldest inhabitant, recollects of every yearly cleansing of the well when "Methuselah" was duly put into the pail till the spring gave him his usual element. There is also another of forty years. The patriarch was nearly blind when last handled by Mr. Francis Clelland at the last cleansing.

ORNITHOLOGY.—There is at present to be seen at Miss Gibb's, Auchinheathe, a hybrid between the Duck and Hen species, consisting of a Duck in body with Hen legs—three-clawed toes and spurs—out of a sitting of six. When it takes the water, along with brothers and sisters, it will then be seen how its propelling propensity will take effect without the web feet. The old one is at present watching her flock round and round the nearest pool with a maternal care. We believe this is considered to be the wonder of the day in this locality.—(*Hamilton Advertiser, July 30.*)

A MONSTER REPTILE.—The "Geological Magazine" states that Mr. E. Hartsinck, of Charmouth, has recently obtained the most perfect Plesiosaurus ever discovered upon the Dorsetshire coast. It was found between Charmouth and Lyme Regis in a bed of marl, intercalated between two of the uppermost beds of the lower lias limestone. The specimen, 13 feet in length, exhibits the entire dorsal view of the skeleton, with very few bones displaced. The great perfection of the specimen lies in the completeness of the four limbs or paddles, of which not only are nearly all the numerous bones preserved, but they are all, excepting a few of the ultimate small ones, perfectly undisturbed from their original arrangement and relative position. It is gratifying to learn that this magnificent Enaliosaurian relic makes an addition to our knowledge of the liassic fauna, as it is a new species of the genus, differing in important points from those hitherto known. This specimen has now been purchased by the authorities of the British Museum, and will shortly be described by Professor Owen.

OUR LETTER BOX.

AGE OF RABBITS (H. M.).—Very young Rabbits may be known by the woolly appearance of their fur; as they get older their coats become more hairy and glossy. When they attain maturity it may be known by the dewlap, which increases for some time afterwards. Advancing years may be known by the length of claws, roughened coat, the projection of the hip bones, and haggard countenance.

YOUNG TUMBLER PIGEONS DYING (S. B.).—It is almost impossible to say why your young Pigeons die unless you give some better account of their symptoms. Are the old birds too nearly related? as that will induce weakness, and proneness to disease in the young. If the old ones neglect them feed on less stimulating food, as they may be too fat, and consequently idle and careless of their offspring. Wheat is very good as a mixture for the old to feed the young with, but small old beans are better food for a continuance. Buckwheat is also a good change, and lentils are very nourishing. If the young die from diarrhoea, feed on beans and some rice. I suppose the Pigeons have access to gravel, lime, and salt.—B. P. BENET.

POULTRY CHRONICLE (A Constant Reader).—The Poultry Chronicle was incorporated with this Journal some years ago.

LONDON MARKETS.—AUGUST 8.

POULTRY.

There is now a full supply of all sorts of poultry, and the trade falls off daily, and we may now look for nominal quotations while London is out of town.

			71.4	49.9	60.2	14	59	4	7	7	17	9	235

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 72.8°, and its night temperature 50.9°. The greatest heat was 92° on the 18th, 1842; and the lowest cold, 32°, on the 21st, 1850. The greatest fall of rain was 1.12 inch.

ORNAMENTAL GRASSES.

GRASSES give a feature to open situations similar to that which Ferns do to those which are shady; some are elegant, others graceful, not a few attain majestic proportions, and all are more or less curious and ornamental. They rank amongst the most attractive and graceful ornaments of the flower garden, and impart a light graceful appearance such as is not afforded by any other tribe of plants. They are, besides, easily cultivated by those who are little versed in horticulture; and in this country the hardy kinds grow freely in most soils and situations, and of such I propose to treat, noticing, in addition, tender kinds which flower in the first year, and

which, though perennials, are not capable of withstanding the winter with us.

PERENNIAL GRASSES.

All or most of these delight in a rich, deep, moist, loamy soil. To do them justice it should be trenched or loosened to a considerable depth, and a liberal dressing of manure or leaf mould worked in if the ground is poor and light. The situation must be open, but sheltered from wind by trees at a distance, otherwise the cold cutting winds of spring and the summer gales destroy much of their beauty. Sunny or warm dry situations, as south borders, are not suitable for them, nor are they adapted for growing in shady places under trees; but open spots on lawns answer well for those which may be planted singly, and ordinary borders for those of smaller growth.

They are increased either by division of the root or by sowing the seed. The first is a ready way of obtaining plants, and is best accomplished when these commence growth in the spring. It consists simply in taking off with a trowel or spade the offsets, with a little root attached to each, planting them in the places required, and afterwards watering them until they become established. The seeds may be sown in the open ground in any description of well-pulverised soil, covering lightly with fine soil. The ground should be kept constantly moist; and a mat, or some such material, thrown over the seedbed in dry weather will secure a speedy germination. The shade must be removed at night, and discontinued after the seeds have braided. After this they will only require copious supplies of water in dry weather, keeping clear of weeds, and thinning if closer together than one in a square inch. It is desirable, however, to sow them thinly, so that there may be no necessity to thin them until they are of a size fit to handle, when the whole may be taken up and transplanted, or pricked-off into beds,

allowing a distance of 3 inches from plant to plant every way, so that they may grow strong, and when of sufficient size they may be removed with balls to their final quarters. When pricked off they should be well watered, and shaded for a few days until established.

The best method, however, of raising the better kinds of hardy Grasses from seed is to drain a seed-pan or pot one-third its depth with some rather large pieces of crocks over the holes in the first instance, some smaller above these, and over all a thin layer of moss, and then to fill the pan to within half an inch of the rim with any light turf-loam with which about one-sixth of sharp sand has been mixed. Level the surface, and sow the seeds thinly and evenly on it, and cover with a little fine soil, no deeper than just sufficient to hide the seeds; then gently press the surface with the hand or the bottom of a flower-pot. Give a gentle watering through a fine-rosed watering-pot, and place in a house with a gentle heat. The soil should be gently sprinkled with water once or more during the day, so as to keep it constantly moist. When the tiny blades appear and are well up, remove the pan or pot to a cold frame, which must be kept close for a few days until the plants become a little hardened, then gradually admit air, and after they are hardened off, remove the lights in mild weather, drawing them on only when drenching rains and severe frosts occur.

When sufficiently large to handle, pot them singly into 48-sized pots in a compost of rich turf-loam, replace in the frame, and keep them close, shaded, and well watered for a few days until established. After this insure them to the open air, and to secure free growth keep them well supplied with water at the root, giving a sprinkling overhead on the evenings of hot days, which will much refresh them. Dryness is very injurious to Grasses, and a badly-drained soil not less so. Perhaps the soil may be naturally light and dry, if so a liberal application of manure worked into the soil prior to planting will be advantageous; and after they become established water them copiously twice a-week with weak manure water during hot dry weather. Good, sound, and rather strong loam suits the majority of the perennial Grasses, and they do well in clayey moist soil, provided it be drained so as to remove standing water from the under strata or subsoil. When once well established they require but little attention, this being limited to cutting away decayed growths; but in the case of Grasses of doubtful hardness and those somewhat tender, the dead portions, on account of the protection which they afford the crowns or stools, should not be removed till the fresh growth is somewhat advanced in spring.

GYNERIUM ARGENTEUM (Pampas Grass).—This is, perhaps, at once the noblest and most handsome of all Grasses. It likes a moist soil, but flowers most freely in that which is of a rather light nature. As a specimen on a lawn, or exhibited singly or in groups in arboreta, and by the sides of or on islands in lakes, it has a charming effect. It is from the plains of South America, grows from 8 to 10 feet high, has proved hardy in nearly all parts of the kingdom, and largely as it has

been planted it is deserving of more extensive cultivation. It is said to form excellent cover for game; the finely serrated edges of the sword-like leaves, however, cut cloth very readily, and unless dogs, beaters, and sportsmen are well protected they will be sure to suffer.

ERIANTHUS RAVENNE.—If anything rather less noble, but more graceful than the Pampas Grass. It grows 6 feet high, and in habit and general appearance seems to be related to the preceding. The plumes are composed of silvery inflorescence, having a light elegant appearance. On a lawn amid masses of bedding plants it will form an object which will be justly admired for its gracefulness and beauty.

ARUNDO DONAX.—As a noble ornamental-foliated plant this is unrivalled in its way. It attains a height of from 8 to 10 feet, and has long graceful leaves, which render it especially suitable for lawns, herbaceous borders, and arboreta. It is also specially adapted for planting on the margins of lakes, pools, and on islands, as it delights in moist soil. It should therefore be well supplied with water in summer when planted in light soils.

ARUNDO DONAX VARIEGATA.—Similar to the above, but with long, broad, elegantly decurved leaves, 2 or 3 inches broad, and from 2 to 3 feet in length, marked with broad silvery stripes their whole length. As a specimen on a lawn, amid bedding plants, or masses of green foliage, it forms a stately and picturesque object. In borders it stands out in bold relief among plants of more humble growth; and planted near lakes it forms a highly ornamental feature, whether examined close at hand or seen at a distance. As a centre bed or neuter it is unique, beautiful, and tropical in appearance. It is unrivalled as a decorative plant when treated as an exotic in the conservatory. It delights in rich deep moist soils, and not being so hardy as the species, it requires slight protection in winter in cold, low, and very elevated situations. Height from 6 to 10 feet.

PHALARIS PHRAGMITES (Striped Ribbon Grass, Ladies' Traces, Gardeners' Garters, &c.).—This is a very common and a very fine Grass. A clump of it growing from 3 to 5 feet high on lawns is no despicable object, and in patches in borders it has a fine effect. It also forms a splendid back row to a wide ribbon-border, and is charming as an edging to large beds, such as those containing Dahlias and Hollyhocks. A deep rich soil is necessary, in order that it may attain its full growth when planted in groups; but it will grow almost anywhere, and for this reason does not receive that attention it so justly merits.

BAMBUSA METAKE (Evergreen Bamboo).—An elegant tree-like evergreen, and grass-like withal. For ornamental purposes this will be much sought after; and if it prove hardy, as it has done as far north as York, where it has made shoots nearly 10 feet high, it will soon be found in every garden where a tropical appearance is appreciated.

BAMBUSA GRACILIS.—A slender and most graceful tree-like Grass. The stalks are erect, their extremities arching gracefully; and the bright grass-green leaves drooping and lashing the breeze, it is a charming object on a lawn, in arboreta, and wherever grace and elegance are desired. Though hardy in many situations, with me in Yorkshire it was cut down to the ground with 20° of frost, and completely destroyed by the severe frost of December 25th, 1860, when the thermometer was at 3° below zero. In warm sheltered situations it resists frost well, and though occasionally cut down to the ground in winter, new shoots rise from the stool, and attain a height of from 4 to 6 feet. It is very handsome and distinct.

BAMBUSA NIGRA (Black-stemmed Bamboo).—Of rather stronger and more erect growth than the last; and having black or brown stalks. This also, like the preceding, is of doubtful hardiness, and is generally cut off to the ground in winter. It rises from the stool in spring, and attains a height of several feet (occasionally 8 feet), and has a stately and tropical appearance.

BAMBUSA FORTUNI VARIEGATA.—A tree-like Grass with exquisite markings like Ribbon Grass. This, if hardy, as it is expected to be in dry soils and sheltered situations, will be a great acquisition. It is one of the most beautiful plants in cultivation.

STIPA PENNATA (Feather Grass).—This is found naturally in rocky places, and is a singular ornamental Grass, growing 2 feet high. Much of the beauty consists in its awns, which

are feathery, and from 6 to 9 inches, and occasionally 1 foot, in length. These gathered and dried form fine ornaments for sitting-rooms, and are not unlike so many Birds of Paradise. It is both beautiful and graceful even when growing, and one of the curiosities of Nature.

FESTUCA GLAUCA.—Elegant, with a glaucous aspect. 1 to 1½ foot.

ELYMUS GIGANTEUS.—Elegant and fine. 4 feet.

ELYMUS HYSTRIX.—A curious and fine Grass, with awns like a porcupine. It is from the Crimea. 2 feet.

STIPA GIGANTEA (Giant Feather Grass).—Rather tall (3 feet), very curious, and handsome. It is from Spain.

STIPA JUNCCEA.—Rush-like, curious, and fine. 3 feet. France.

HIEROCHLOE FRAGRANS.—An elegant dwarf Grass, and sweet-scented. 1 foot. North America.

BRIZA MEDIA (Trembling Grass or Mediate Quaking Grass).—Well known, pretty. It abounds in many pastures and meadows. 1½ foot. Britain.

MELICA ALTISSIMA.—Highly ornamental. 4 feet. Siberia.

MELICA NUTANS.—Curious and fine. 1½ foot. Britain. (Mountains).

MELICA UNIFLORA.—Pretty and of humble growth. 6 ins. to 1 foot. Britain.

AIRA ARUNDINACEA.—An elegant reed-like Grass, attaining a height of 3 feet.

A. CESPITOSA VARIEGATA.—A fine striped Grass. Makes a splendid row in a ribbon-border, and is pretty in borders. 1 to 1½ foot.

AIROPSIS CANDOLLEI.—A curious small Grass, worthy of a place in every garden. It is named in compliment to De Candolle.

TRICOCHLOA FOLIOSA.—Of dense growth though small. Curious. 1 foot. North America.

TRICOCHLOA LONGISETA.—Elegant and curious on account of its long awns. 1 foot.

CERESIA ELEGANS.—An evergreen and fine Grass. 2 feet. Peru. It is only hardy in warm situations.

CENCHRUS SPINIFEX.—A Grass producing thorns. Very curious. 1 to 1½ foot.

PIPTANTHEUM PARADOXUM.—Tall and curious. 3 feet. France.

PANICUM PROLIFERUM.—Curious. 1 foot. North America.

ARUNDINARIA MACROSPERMA.—A large, fine, reed-like Grass of noble proportions, often attaining a height of 6 or 8 feet. North America.

TRIPSACUM DACTYLOIDES.—A very elegant and really ornamental Grass. 4 feet.

MILIUM MULTIFLORUM.—Fine. 1½ foot. South of Europe.

ANDROPOGON ARGENTEUM.—As its name implies, this has a silvery glaucous aspect. It has a fine appearance. 2 feet.

DACTYLIS GLOMERATA VARIEGATA.—A variegated form of the species, growing about a foot high.

D. GLOMERATA VARIEGATA ELEGANTISSIMA.—Rather more dwarf than the last, with broader and more evenly-striped leaves. It is of dense growth, and furnished to the soil, towards which its leaves droop gracefully. It withstands drought well, and also wet, and is one of the finest variegated plants for edgings, ribbons, and general decorative purposes.

The above are some of the most ornamental of the Grasses, but many others, the names of which do not occur to my mind just now, are curious and pretty.

I have omitted mentioning three varieties of the Pampas Grass, because I wished to ask if any of your readers have succeeded in obtaining new varieties of Grasses by adopting other means than cultivation. Most of our improved varieties of cereals are accidental sports. Cultivated plants are more liable to sport, especially when several generations removed from the original type, than those under indifferent cultivation, or in an almost wild state. The Pampas Grass was but recently introduced, and we have three distinct types of the species—viz., *Gynerium argenteum floribundum*, which has larger and denser inflorescence than the parent; *G. argenteum roseum*, the panicles of which are of a fine rosy hue; and *G. argenteum elegans*, which has snowy white plumes, presenting a tufted appearance, yet having a sub-conical outline, and drooping in character. Altogether this is the finest form of the species, and presents a combination of elegance and effect in its foliage and bloom found in few plants.

Then, as to variegation, will seed from a variegated Grass produce variegated or plain-leaved plants? Geraniums, I am aware, will produce both, some variegated, and others green, the one further from the type, but the other reverting to it, and this when impregnated with the same pollen. Geraniums, however, have been so crossed that they will sport in almost any way; but from seed of a variegated plant but once removed from the species, will the progeny be like the parent, or revert to the original type? In other words, is variegation continued by the pollen, or is it peculiar to the individual plant? and will the pollen of a variegated plant have any effect in producing a variegated progeny if applied to the stigmas of green-leaved plants? Some speak of variegation as if they could accomplish it at will; but it appears to me as if Nature was the most prolific source of variegation, and that man has very little, if any, control over its production.—G. ABBEY.

(To be continued.)

MY ORCHARD-HOUSE.—No. 7.

I CANNOT help expressing how flattered I am at the kind praise of my good friend Mr. Rivers. It is a great inducement to continue my efforts to develope and promote the "good cause," as Mr. Rivers used to call it in our former correspondence. And that it is a "good cause" it would be easy to prove from the interesting letters received here on this subject alone. There is a very great demand for knowledge up to the present hour, and nothing could be more acceptable than information such as Mr. Rivers suggests—namely, as to the date of fruit ripening in different localities—in orchard-houses of course. In this way data of great value to any amateur about to erect an orchard-house would be obtained. He would thus know at once what sort thrives best in his neighbourhood and situation; and also ascertain the periods at which he might depend on fruiting the various sorts in succession, so as to have no waste, nor find his fruit ripening just when he did not need it.

Orchard-houses being a new structure, the periods of ripening in out-door fruit could not be a safe guide—indeed, in the case of Peaches, would be none at all. We are on the eve of the introduction of quite new classes of fruit, which themselves will become, as Mr. Rivers says, alluding to that remarkable new Peach, the Honey Peach, "the parents of quite new races." Any one who has tasted this Peach will be satisfied on this point. It has a strange tropical flavour quite peculiar to itself. So has Golden Purple, a Georgian Peach. This last has the flavour of rose water, and is a fine fruit, something like Noblesse. If this be true of Peaches, it is equally so of Plums and Cherries. Many of the new American sorts are delicate and worthy of in-door cultivation. How important, then, to ascertain clearly which sort is suitable for the north and which for the south. Nothing vexes and discourages amateurs so much as making mistakes in these matters. We are, most of us, people of moderate means; we like our orchard-houses, but we dislike their becoming expensive, and, besides this, unprofitable. I have seen men build such houses, stock them unadvisedly, then become discouraged, leave them to ignorant servants or gardeners of the old school (who hate these new-fangled things), and the end has been, that much money has indeed been wasted and orchard-houses decried.

Now, it strikes me that the more information we amateurs can give each other, the less frequent will be failures in future. The Editors have kindly consecrated a column to us, so let us endeavour to put it to profit. Let us, then, do as Mr. Rivers suggests, begin by comparing dates of fruit ripening, for this is just the season.

Last week I had a letter from a clever amateur living near Dundee, 450 miles north of London, and 650 north of Guernsey. He describes his fruit culture accurately, and certainly the difference of situation is enough to make comparisons between our houses.

Suppose, then, I had one hundred such correspondents from various parts of England, each describing the period of ripening in Peaches, Plums, &c., their sizes, and the shape, dimensions and aspect of the house, I do not hesitate to say that all this information could be arranged in two or

three columns of THE JOURNAL OF HORTICULTURE, that it would be a labour of love to me, that it has never before been attempted, and that only by means of such a Journal as this could such valuable matter be brought together at so little cost. At a glance would be seen how certain fruits ripen in their respective zones, and how great a difference 600 or 800 miles would make in the same fruit, whether east or west had any advantage, and how many days could be gained by situation or form. To my mind, nothing in orchard-house culture is more important. I have myself helped to organise and plan ten or twelve houses, and feel a certain responsibility as to their welfare, and how best to work them. Probably we should find lean-to houses much a-head in point of time, and large, well ventilated buildings doing best of all.

One other point is of much importance. Do orchard-houses gradually and steadily, without falling back, advance the period of fruit's ripening? I am convinced they do; but I should like to have the opinion of some others better able to judge. If they do thus advance the ripening of many fruits, what a precious gain have we in this! Time is everything in fruit culture. Time is money when we outstrip the market by even a week. In our own case, by carefully selecting the sorts, and by the above-mentioned hastening of their previous ripening, we are able to send fine Peaches and Nectarines, grown in an unheated house, in time for the London season. We should also be able to compete with Algerian Peaches in the Paris market, we being, as it is, a fortnight in advance of Montreuil. But this was not the case six years ago for example, and it is the result of careful attention to the nature of the fruits.

Orchard-houses are rising up in the Channel Islands (mine being the original one), and, as we export Grapes largely, it may happen that we shall, by-and-by, export Peaches also. Therefore, it is well to know certain facts before these houses are organised for this trade. What is advantageous for the Channel Islands must also be so for Devonshire and Cornwall; at least, we have much to contend with—much rain and continual wind, with cloudy skies. Only our autumn, long and warm, stores up heat, as also does the sea around us.

By this date about one-half of our fruit is gone. I have just measured Exquisite, and it is already about $10\frac{1}{2}$ inches in circumference. Stump the World, a splendid Peach, is not so advanced in size this year, but shows signs of becoming earlier. Hunt's Tawny Nectarine I recommend to amateurs. It is a little inclined to be bitter, and is a little below medium size, but it is early, and bears well. Rivers's Orange Nectarine is a great favourite with the ladies. Its colour, luscious flavour, and fertility, are admirable. I speak of it as getting over, it is so early with us. Violette Hâtive and Elrige are also nearly over, except in the east or late house. Brugnon Imperial has been ripe since the 7th. In a basket from one large cordon tree the fruit weighed about 4 ozs. each, and were, generally, 8 inches round. The flavour and colour were first-rate, and it was the same with Crawford's Early Peach, from one bunch of which we selected twenty-seven, gorgeous in colour, and about 9 inches round, on the 30th of July. Duchess of Oldenburgh is a great acquisition. It contrasts admirably with the darker Nectarines. It has been ripe since the 6th. This kind has actually advanced in three years, from the 18th of August to the first week, or about twelve days. Acton Scott is no favourite of ours. Ever since Early York has been introduced, its day seems gone. Pêche Abec, which is always a remarkably fine Peach, is never prolific. After trying it in many forms and places, it remains a grand fruit, but not fertile. It is also one of the few stationary in period of maturity, ripening July 29th, 25th, and 25th, during the last three seasons. Golden Purple has advanced from August 4th in 1862, to July 20th this year, without diminishing in size or appearance. It is first-rate. Brugnon Violet is just ripe, and very prolific. Is not this our Roman? It is not, however, a clingstone. Belle de Doué was ripe from the 19th of July. As a diagonal cordon in a warm place, it has advanced thirteen days in eight years.

I hope, however, to prepare another article to prove how, among seventy varieties of choice Peaches and Nectarines, nearly, if not all, have advanced gradually, without deterioration of quality (which is the danger), from five to twenty

days in the course of eight years. I have kept notes during this period sufficiently to ascertain this, and for the last four years with great care.—T. COLLINGS BRÉHAUT, *Richmond House, Guernsey.*

SIR JOSEPH PAXTON ON THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITION.

THE following letter has been addressed to the Assistant Secretary by Sir Joseph Paxton, M.P.:—

"7, Pall Mall East, London, July 20, 1864.

"SIR,—Having been requested to give my opinion as to the nature and character of Exhibitions which the Royal Horticultural Society should encourage for the true advancement of Horticulture and its accompanying sciences, I have drafted out this letter, in order to form a foundation, or data, on which this matter can be discussed, and I trust with a good result.

"1. No doubt the result of the Society's Exhibitions has, in many respects, been very advantageous to the cause of Horticulture, particularly the earlier ones. They have encouraged great improvements in the culture and management of plants, particularly in such plants as can be produced in flower at what may be called the London fashionable season; but they have by no means been productive of unmixed good. They have brought into existence an unnatural and artificial condition of things, which is not only objected to in the interest of gardeners themselves, but is also opposed to the interests of the public, by causing what may be termed a spasmodic effort and exertion, which at other seasons of the year is unemployed and, to a great degree, unproductive. I may illustrate this by stating that a good many years ago (and the same state of things now exists to a certain extent), I called to see a first-class London garden, forgetting that it was one of the exhibition days, and I found only about six or eight plants in the garden, the others having all been trained, like a horse, for racing, and had been taken to the show to win the stakes. In the same season, some time after this, I called again, and found the plants, having been their round of racing, all flowerless, and beginning to be placed under training for the next season for the same purpose; and this training was effected by keeping some plants back and forcing others, so that they might all flower together, and such plants as would not bear this treatment were not cultivated.

"2. Every one, of course, says he has a right to do what he likes with his own plants, which I do not deny; and if a gentleman does not mind being ten months in the year without flowers in order to make this great display, I have no fault to find with him; all I contend for is, that should not be the main aim and scope of the Exhibitions of the Horticultural Society. In one respect the Exhibitions of the present day have produced a good result by giving prizes for collections of beautiful-foliaged plants, as the culture of these plants, which look beautiful all the year round, is thus stimulated, and they are a great improvement in the garden.

"3. But in other respects these great show-cultivators grow very few plants which do not flower at the show seasons, and therefore leave the flowers which might be cultivated with great effect for other seasons of the year without much attention.

"4. The true object of Horticulture should be, in my opinion, to increase the enjoyment derivable from it, and to diffuse it as widely as possible; to enable the owners of gardens to get the greatest amount of pleasure and satisfaction from their possessions; and to enable the general public to procure the greatest number of fruit, flowers, and vegetables in the greatest quantity, of the best kinds, and at the cheapest prices.

"5. In order to carry out this, there should be something like a continuous exhibition, so that a gardener would have no interest in forcing his plants unnaturally into flower; but if he had a beautiful specimen at any time he would know he could exhibit it where it would be seen and appreciated, and its merits rewarded. When the Horticultural Society was in its palmy days, one of its great sources of benefit and attraction was the fortnightly shows at their great room in Regent Street. It was then the practice for

any gentleman in the country, if he had a new plant or a new fruit, to send it to one of these exhibitions at any time in the year, and the nurserymen brought every new plant there from their respective establishments. Dr. Lindley explained the nature and properties of everything as it appeared in each exhibition in his lucid and agreeable manner, in which on this subject he has no rival, and these meetings were intensely fashionable, and often densely crowded.

"6. When the Horticultural Gardens at Chiswick were the leading gardens in the country for new plants, many gardens were supplied thence, and so they were never without great interest. They could not trust altogether to country gentlemen and nurserymen for plants for exhibition, and when the entries were deficient the shows were made up of beautiful plants from the Horticultural Gardens, though then a certificate of merit from the Society meant something, and was prized at a high rate; it insured the sale of any plant which received it, and often practically represented a prize of some hundreds of pounds sterling, as many nurserymen had orders before the exhibition closed for very large amounts. It therefore appears to me that these fortnightly exhibitions should be renewed at once, and every attraction given to them; and, considering the increase of commercial transactions relating to Horticulture, the facility of carrying anything from a distance, and the great influx of visitors into London in the season for a temporary sojourn for the spring and summer months, it would be well to try a weekly exhibition without the descriptions, which, in point of fact, would almost amount to a continual show; and they should be held in a place suitable for plants, where many nurserymen would not mind allowing them to remain all the time they were in full flower. One or two of the great shows might be still held in the Gardens, where the fashionables could attend to show themselves and look at each other, which they do on these occasions quite as much as at the flowers.

"7. It would be too much in a letter of this sort to go into details as to how many branches of Horticulture have remained stagnant for many years past; though it would not be irrelevant, it would occupy more space and time than I can now afford to give to it. But there is one subject that has pressed upon me so long, and I am so convinced of its damaging effects upon the commercial part of the supply of the finer fruits in the public market, that I cannot help reverting to it in this letter, and that is, the growth of fruits for sale by private establishments, in competition with the market gardeners. Many gentlemen keep gardens, partly for their own use, and partly for the sale of the produce, which they sell to cover part of the gardening expenses; and this is done to a very large extent, and by some of the highest private garden establishments in the country. The result is, that fruit, with all the facilities of cheap glass and cheap coal all over the country (compared with forty years ago) is absolutely dearer than it was forty years since: while the produce of real market gardens is perhaps 50 per cent. cheaper, and 100 per cent. better, the forced fruits in which the private establishments compete have made very little progress in goodness. If you went to Covent Garden Market between thirty and forty years ago and looked at the fruit, you would find the fine Grapes were grown by Mr. Andrews, the great market gardener at Vauxhall, Mr. John Wilmot, of Isleworth; or some other good market gardener of the day: whereas, if you go there now, the same kind of fruit is from some private garden; and supposing a large quantity of fruit is wanted for a big party, none of the great fruiterers will undertake to supply you until they have written or telegraphed to some private establishments to know what they can get.

"8. The first question that naturally strikes you is, How is the public worse off for this change? I can answer this, I think, to everybody's conviction, in a few words: A private establishment will very often sell in the early season 1 lb. of Grapes or a dozen Peaches, regardless of cost, at a price which it would ruin a market gardener to attempt. This price will content a private gentleman who does not know the cost of growing them, but competition at these prices would ruin any market gardener, who is nearly deterred from growing them at all; and, therefore, the regulation of the supply of the market is left in the hands of these limited

private establishments. If the market gardeners were not met there, they would try to excel each other in the cheapness and goodness of the fruit, as they do in all other things, and in a short time the market would have a regular supply at half the present cost of spring fruits, which is not attempted now on a scale large enough to compete with the great number of private establishments which send the best of their things, and pocket their losses, and the public have in consequence a very limited supply. I daresay it answers the purpose of the fruiterers very well, but it is very detrimental to the public.

"9. And now, sir, before I close my letter allow me to say a word or two about what is done in the sale way by the Royal Horticultural Society. It is quite legitimate and right to propagate and distribute any new plants (which it has brought into the country), to Fellows, but I object *in toto* to buying new plants, cultivating them, and balloting for them; this is, allow me to say, an infringement of the legitimate business of the nurserymen, who can do it much better and cheaper than the Society can.—I am, sir, yours very truly, JOSEPH PAXTON."

"PROCEEDINGS OF THE ROYAL HORTICULTURAL SOCIETY."

THE August, September, and October Numbers, all in one! of the "Proceedings of the Royal Horticultural Society," have come to hand, and we thus learn that, on the 28th of August, there is to be a "Show of the trial flowering plants and fruits at Chiswick, with promenade." Now as the 28th of August is a Sunday, and not a Saturday as announced, it would be as well if the Assistant Secretary informed the Fellows which is the day on which the promenade is to take place. We are told, also, that there is to be, on the 7th of September and following days, a Show of cut flowers of all the autumn-blooming florists' flowers. As the Crystal Palace Company have also for some time announced their great autumn Flower and Fruit Show for the same days, would it not have been to the interests of the Royal Horticultural Society if another occasion had been chosen for their autumn Show? Greater lights always outshine the less, and we know what chance the South Kensington Show will have against that at the Crystal Palace, when both are held on the same day. Is the Assistant Secretary away wool-gathering again?

GARDENING IN INDIA.

PERHAPS it may interest your readers to hear something of the plants usually seen in gardens in India. I shall speak only of central India and the N.W. provinces, Bengal Presidency. And first about Roses.

There are not many Roses generally known. I had but fourteen kinds, and few people, I believe, were in possession of half that number. I had pink and crimson China, white and pink Gallica (from which Rose water and attar are procured), the Bourbon (called in India "Rose Edward"), Multiflora, Microphylla, Dog Rose, Hill Rose (a beautiful evergreen double white climber), white and yellow Tea-scented, Musk, a very small cluster Rose blooming only in hot steaming weather, and the double yellow Cashmere Rose. This did not bloom with me, but, judging from the leaf, I suppose it to be the Persian Yellow.

The Tea Rose is worth all the others put together. I only speak of the white—Devoniensis I think it was; the yellow had not bloomed with me before I left India. From November to April the Tea Rose was a picture of beauty. During the hot season it was not worth looking at, but in the cold nothing could exceed its beauty and luxuriance. I took notes of one that I had especially cared for. When two years old it was 4 feet in height and 12 in circumference. One morning in February I counted ninety-one blossoms fully opened. The centre of some was blush, of others yellow, and those a day old were edged with the loveliest lilac. The buds were innumerable—I should rather say I became tired of reckoning them when the number reached six hundred: there certainly were more than double that number. A native in charge of one of the public gardens came one day to see one of my Tea Rose trees. He went on his knees to examine it, and for some minutes

said nothing but "How beautiful! how beautiful it is!" He was really fond of flowers, and had never seen it before. I wish I could make Tea Roses grow with me now, but they constantly die off. I suppose I cannot get out of the Indian way of treatment.

Many of your readers, probably, have relations or friends in India, and perhaps would be glad to know what seeds would grow easily there if sent from Europe. Stocks grow splendidly; so do Camellia and Rose-flowered Balsams. Petunias will take possession of any ground in which they are sown, but they seem to have new varieties every time they bloom. Verbenas also spring up self-sown. Salvia patens grows well, as do many others of the same genus—one is a native of India. In the hills Pelargoniums bloom beautifully. A gentleman once told me his plants usually had eleven in each bunch of flowers; indeed, I saw many of his with that number. Fuchsias also grow well; but almost any flower will succeed in the hills.

No one can have an idea of the splendour of the Camellia and Rose Balsams in India. Of course the climate is suited to them, but these varieties are unknown except to a few. I have seen plants 3 feet high and the same in diameter loaded with enormous blossoms, so that scarcely a leaf was visible.

I must now tell of a sight I once witnessed and which I can never forget. At a station in Bundelcund I one year had some superb beds of Stocks. They were from German seed, and I do not think there were a dozen single-flowering ones in as many beds. One morning I had just left the garden, when I was recalled hastily and eagerly by a servant. Much surprised at the man's apparent excitement, I ran quickly to the trelliswork at the entrance where he stood, making signs to me to come as quietly as possible. He whispered, "Look at the 'Ishstocks!'" as he called them. There were ten or twelve large beds full, each with distinct colours. There, balancing themselves in the air, many with their long bills inserted in the blossom, were multitudes of tiny birds, looking like living gems, fluttering and glancing in the sunlight. I suppose they were humming-birds, but it is impossible to give an idea of the beauty of the sight. They showed to most advantage on the white Stocks, almost every blossom of which had a ruby and emerald or sapphire birdie enjoying itself amazingly to all appearance. There were about thirty plants in each bed, and the spikes of flower a foot in length, and all covered with these living gems. I stood in silent admiration, until, all at once, they disappeared as suddenly as they had come. The native (an old man), assured me he had never even heard of them before. They were never, to my great regret, seen again during our residence there.

The shrubs, bulbs, and climbers at this station were very beautiful—more so than at any place where I had previously been. I cannot conclude without saying that I believe the Bourbon Rose is a native of India. I have trespassed too much on your space to give my reasons now. If these scattered notes are acceptable I shall be happy to add to them at some future time.—TEA Rose.

[We shall be glad to hear further from you on this interesting subject.]

NEW APRICOTS.

I HAVE the pleasure to send you a small box of fruit containing three varieties of Apricots, and one early Pear.

No. 2. Royal de Luxembourg, you already know. [This is a variety of the Peach Apricot, having a covered channel on the back of the stone, and a bitter kernel. It is smaller than the Peach Apricot, and very richly flavoured.]

03 is De Jonghe's Sweet Kernel Apricot, the seedling tree of which produced in 1863, 5330 fruit. This year it has more, and we have already gathered 1530. I have fruit on trees four or five years old, and upwards of thirty seedlings from the same varieties.

[De Jonghe's Sweet Kernel Apricot is a small fruit about the size of what is cultivated in this country under the name of Breda. Judging from the shoot which Mr. De Jonghe has sent, the tree is a prodigious bearer. The shoot is a forked one, and on a space not more than 7 inches long there are

twenty full grown fruit, set as thick as Bullaces. The flavour is very excellent, and the stone is as sweet as an almond.]

90 is De Jonghe's Diamant. I consider this variety the most beautiful and the best that exists in cultivation at the present time. The seedling tree is healthy, hardy, vigorous, fertile, producing fruit superb in form, and of exquisite flavour at its perfect maturity. As the diamond among precious stones surpasses all others, I have, by analogy, designated my Apricot by this name, associating it with my own as the raiser of this variety.

[This is allied to the Peach Apricot, and considering that the fruit sent us has been grown upon a standard in the open ground, the state in which we received it indicates an early habit. It was not, however, sufficiently ripe to enable us to judge of what the flavour will be when at its perfect maturity. The fruit is large and handsome, and the tree appears to be very fertile, judging from the quantity of fruit on the small spray.]

No. 878 is Fondante de Cuerne Pear. Cuerne is the name of a village near Courtrai (Flanders). The popular name of the Pear is Suiker Peer (Sugar Pear). It ripens during the last fortnight of August; but on the Pear stock in strong, cold, humid soils, the maturity of the fruit is prolonged to September. I will send you perfect fruits in the next package, or in the end of the month, with two other early varieties.

Notwithstanding a very great heat, and a continued dryness, accompanied with violent winds, the Pears are unaffected on the trees. This year we shall see many of my seedlings in all their perfection.—J. DE JONGHE, Brussels.

CARHEAD, YORKSHIRE.

CARHEAD, the seat of W. B. Wainman, Esq., lies quite out of the way of tourists and travellers, up in the pretty and romantic district of Wharfedale, and is more frequently visited by agriculturists than horticulturists; for who has not heard of the Carhead pigs and their achievements at the various agricultural shows in the kingdom? We have before described this place in our pages at a time when flower gardening was the chief feature; but this department has been greatly curtailed, and attention is now devoted chiefly to fruit-growing. On the lawn and near to it, are a few noble specimen Conifers—*Abies Douglasii*; 40 feet high; *Pinus cembra*, 20 feet high, and very symmetrical; an *Arbutus procera*, 15 feet high and well berried, standing out perfectly hardy on the lawn. There are glorious specimen Thorns, and a fine collection of them; and these and the large quantity of Rhododendrons about the place alone create a superb display of flowers in the spring.

The old vineeries adjoining the lawn and close to a mass of large trees on the west side, have hitherto not produced fruit of fine quality, and have been very subject to shanking; but Mr. Ascough, the present gardener, last winter covered the border with canvass, commencing in September, and in February commenced using hot dung over the roots in addition to the canvass, replacing the dung as it became exhausted. Previous to doing this Mr. Ascough removed the old surface soil as far as the roots and replaced it with fresh. There are now by far the finest Grapes seen at Carhead for many years, many of the bunches of Black Hamburg weighing 4 lbs., and the berries are large and the bunches compact. White Frontignan also is doing well under the same treatment, and the bunches are fine. Against the back wall of the conservatory the Guava is fruiting well, and a large Desfontainia is in glorious bloom. Passing from these houses to the kitchen garden, we came across a very telling riband the whole length of the kitchen garden, planted with Blue bedding Cliveden Pansy in front, Variegated Alyssum, Scarlet Geranium, yellow Calceolaria, Perilla, backed up by Gladiolus Brenchleyensis, and the wall covered with climbing Roses.

In the kitchen garden on a heated wall facing the southwest are some very fine Apricots, fully 8½ inches in circumference, unusually large for this cold district. Princess Royal Pea is prized here for its productiveness and dwarf habit, and Beck's Dwarf Green Gem Bean is a most productive and rich-flavoured little sort, exactly suited to a gentle-

man's table. The Chusan Marrow, a new kind introduced this year, is bearing here. It is much more shrubby in habit than any other, is of a striped green colour, of the same shape as the old kinds, and bears freely, the plant not occupying so much ground; it is as delicious as the Custard Marrow. Melville's Variegated Kale is also grown here, and in large shrubberies is a highly ornamental plant. Tom Thumb Lettuce is a firm and very small Cabbage Lettuce, not at all coarse for salads; and Wilson's Prolific Cucumber is a most abundant bearer and just the sort for amateurs. Mr. Ascough speaks very highly of Dear's Early Prolific Potato, a small-hauled kind, only five or six days later than the Ashtop, of medium size, but a wonderful cropper and of excellent flavour. Some good-sized bush Apple trees which had been in an unhealthy and unfruitful state were lifted a year ago, last autumn, and replanted in good soil, and they are now in full health and loaded with fruit. Amongst little-known Apples, New Hawthornden, a fine baking sort, and Betty Geeson, a large kitchen Apple, seem to be very productive on small trees.

A block of vineeries and Peach-houses is at the back of the kitchen garden. In one of these, a span-roofed Paxton-house, with the soil largely made up of lime rubbish and stones, there are some fine Peaches, Grapes, and an enormous crop of Figs. Several kinds of Grapes are grown here, and the following remarks supplied by Mr. Ascough, will give his experience of these kinds in one of the coldest districts in Yorkshire:—

“CHASSELAS ROYAL.—Bunches shouldered. Berries round and of a nice medium size, yellowish white when ripe, and apt to crack when ripening. A great bearer and a strong grower. Ripens a little earlier than the Black Hamburg, and is well adapted for pot culture.

“CHASSELAS VIEET.—Bunches medium-sized. Berries large, round, when well ripened of a pale amber colour; flesh juicy and sweet. A strong-growing variety and a great bearer. It is a good pot Vine.

“LADY DOWNES’ is one of the best late Grapes. Bunches large, and the berries of a good size, and hanging a long time without shrivelling. It is a free grower and good bearer.

“GROS MAROC.—Bunches large and compact, with shoulders. Berries very large and long, tapering a little both ways; when ripe of a dark reddish purple colour, and covered with bloom. This is an excellent Grape, and will ripen with Black Hamburg; but it requires a good heat when in flower to set its fruit well. It is well worth growing.

“WHITE FRONTIGNAN is fruiting here well, and is one of the best white Grapes in cultivation when well grown. I think it should be more cultivated than it is, for there is none surpassing it in flavour. Bunches long. Berries medium-sized and round, when thoroughly ripe greenish yellow or amber; flesh firm, juicy, very rich, with a fine Muscat flavour. This forces well either in pots or planted out, and will ripen with the Black Hamburg. It is an abundant bearer, but requires a good bottom heat to ripen it to perfection.

“MUSCAT OF ALEXANDRIA.—This is a good Grape, but it requires good treatment to grow it to perfection. Bunches very large and oval, with a fine Muscat flavour.

“MUSCAT OTTONEL.—Bunches very small but well set. Berries small, skin thick; flesh tender, but not plentiful, having a very strong Muscat flavour. It is an early Grape, will ripen a fortnight before Black Hamburg, is an abundant bearer, and fruits well in pots. We think it is not worth growing for anything but flavour, the berries are so small.

“MUSCAT ST. LAURENT.—Bunches and berries similar to those of Muscat Ottonel; flesh tender and juicy, with a strong Muscat flavour; colour pale amber when well ripened. An abundant bearer in pots. It ripens with Muscat Ottonel. The foliage of Muscat St. Laurent is much more indented than that of Muscat Ottonel, which constitutes the only difference we can perceive in the two. [The berries should be roundish oval.]

“MUSCAT HAMBURGH.—This fine Grape is growing on its own roots here in an inside border, and is carrying some fine bunches.

“PURPLE CONSTANTIA.—Bunches long and tapering, with

small shoulders. Berries medium-sized, dark purple, covered with bloom; flesh juicy and well flavoured. This Grape is well worth cultivating, it being a free grower and a good bearer.

BLACK FRONTIGNAN.—This is a free-growing Vine and a good bearer. Bunches medium-sized and cylindrical-shaped, some having shoulders and some none. Berries round and unequal in size, but generally of a medium size, and of fine flavour.

"**GOLDEN HAMBURGH** is carrying some fine bunches, but I find it a shy bearer, though an excellent Grape, rich and sugary when well grown.

"We also have Buckland Sweetwater, which is a good Grape, and Royal Muscadine and Trentham Black are doing well."

VISITING SOME DISTANT GARDENS, AND HOW TO SEE THEM.

THE language of poetry, like that of the abstract sciences, would seem to require revision now and then, when new ideas or improved systems render old-established expressions erroneous. The flowery month of May, which has been sung by poets for many centuries, is now almost superseded by August, which long ago reigned only over ripening fruits and harvests of golden grain; for the flowering plants by which the parterre of the present day is embellished put on their gayest apparel during this month. Go where we may, masses of scarlet Geraniums, Lobelias, Calceolarias, Verbenas, &c., meet the eye; and though some critics may question the propriety of sacrificing so much for this display, there is no question as to its gorgeous character. August, then, being so essentially a month for gay flowers, let us take a hasty glace at the principal features of this month's embellishment, and endeavour to find out in which way the improved practice of one district may be imported into another.

As flowers in August have become so numerous, and as beds planted with the most popular plants are then in full beauty, it is incumbent on their ardent admirers to visit places within reach where the greatest perfection in the floral department of gardening is attained. There are comparatively few places of note at which bedding plants are not numbered by thousands; in fact such plants have in a great measure superseded other and more legitimate occupants of glass houses in the winter, and in spring every corner under cover is filled with them, so that the gay appearance which they present in August is not produced without a due share of trouble and expense at other seasons. Let us now try to discover how the greatest amount of information on this department of gardening can be obtained, and endeavour to induce our readers who may visit remarkable places to point out what is worthy of notice, and as several gardens of great importance are open to the public at this season, and those that are not so are often, nevertheless, accessible to gardeners of standing, it follows that there are many opportunities of noticing what is going on in the ornamental department of the gardening art. In the first place, I would suggest to all employers who wish to keep pace with the times the expediency of making arrangements for their gardeners visiting one or two of the metropolitan or other good horticultural shows during the summer, and to induce them in August to devote a few days to some tour, near or distant, where the best examples of gardening in its different branches may be brought before them. Railways offer great facilities for undertaking long journeys at a reasonable rate, while the journey itself is not always lost on the observing and reflective traveller; different modes of cultivation and a variety of crops being presented to his view, in addition to the equally important natural features of soil and climate. Indeed, a railway journey may be as instructive as a visit sometimes is, if the traveller keep his eyes open, and compare the appearance of the things he sees in his journey with those he left at home.

It would be premature in a paper like this to point out any particular routes to the intending tourist. I would, however, advise him to make himself as well acquainted as possible with the neighbourhood he is about to visit before he starts, and to arrange his plans beforehand; for though

local circumstances may compel him to depart in some measure from it, still the general route which he intends to take, and the places he may regard as his head quarters for the time, ought to be as much as possible adhered to. The "Gardeners' Year Book" contains a list of the most important gardens in the kingdom, and the names of the railway stations from which they can be the most conveniently reached; and I should recommend all intending to visit gardens to possess themselves of a copy previous to starting. By it they will find that by making an important town—say Leeds or Liverpool, their head quarters for a night or two, some important gardens may be seen, and there are, doubtless, many places well worth seeing which have not yet appeared in the list above alluded to. The tourist may, in some cases, be guided by the information he obtains in the neighbourhood, or, perhaps, some experienced person will point out what places of importance may be conveniently reached from certain points, which for distinction we may call bases.

Although my knowledge is far from being perfect, the names of a few places within easy access of Liverpool by rail, may, perhaps, be of service to the general reader. At the same time I must observe, that as it is now some years since I visited some of the places mentioned, it is possible that greater restrictions may be made as regards visiting some of these places.

Assuming, then, that a tourist anxious to see all that he can in the gardening way, should arrive at Liverpool late in the evening, his first, and, probably, only duty for that night is to secure comfortable lodgings. Unfortunately, I am not in a position to inform him how to act in that matter, further than saying that the inferior class of inns in Liverpool are by no means either the cheapest or most comfortable.

Quarters having been obtained—say near the centre of the town, let the traveller make arrangements for starting early; and presuming him to be determined to see all he can in a limited time, he might rise as early as 5 A.M., and if a stranger he might take a stroll in the town till 6 o'clock, when he might make his way to the Botanic Garden, which is at the north side of the town. This garden when I visited it last year was second to none I met with in a wide circle round, for the good keeping and variety of its floral display. I may state that the character of the garden was such, that scope was given for plants not usually met with being employed for bedding purposes. The contents of the glass houses are, however, for reasons that need not be explained, not accessible to the public until a later hour; but there is enough outside to interest the looker-on for a couple of hours.

After breakfast he may start again for a short stroll towards the great centre of attraction—the Exchange, near which is the fruit and vegetable market, which is well worth inspection; but he must not delay long, for he will have to visit Chester, and the princely seat of the Marquis of Westminster near that ancient city.

Crossing the water to Birkenhead in one of the boats, a pleasant railway journey of twenty miles will bring him to Chester. I would not advise the traveller to spend any time in looking over the antiquities of this old historical city at present, but to push on to Eaton Hall, the seat of the Marquis, which is about three miles off; and if he walk and take the shortest route he will pass through some pleasant meadows by the side of the apparently deep and noble river Dee. At Eaton Hall he will see one of the happiest examples of an embroidered flower garden intermingled with beds for bedding plants, the whole being on a scale befitting the richly decorated character of the mansion, which exhibits to the fullest extent the varied embellishments of which gothic architecture is susceptible. The kitchen garden and forcing-houses are also in character with the magnificence of the place, while the surrounding shrubberies offer examples of Conifers, and other remarkable objects. I will now leave the visitor to make his way back to Chester, and if young and active most likely he will be inclined to take a circuit round the city walls, which are in excellent condition. The Rows, as they are called, or what a stranger would term the principal or High Street, must also be inspected, and the quaint features of a bygone age will be observed.

Supposing him to return to Liverpool the same night, there is plenty to see in the neighbourhood of that town for

another day or two. In the first place, I would advise him to visit the extensive Graperies of Mr. Meredith, of Garston, which is some four or five miles from Liverpool, but I believe now united to it by rail. There, amongst a number of other houses devoted almost exclusively to the cultivation of the Vine, are two span-roofed structures, each 144 feet long by about 30 feet wide. These had been but recently planted when I saw them, but others which were in full bearing showed unmistakably that fruit as fine as Mr. Meredith sends to the metropolitan exhibitions could be sent to every show in the kingdom, the quantity being so large, and the quality so good. To the aspirant for honours in Grape-growing, a visit to Mr. Meredith's place cannot possibly be otherwise than highly interesting.

Eastward from Liverpool some ten miles, more or less, is Knowsley, the princely seat of Lord Derby, which is also a celebrated place for fruit-growing; Peaches in particular do remarkably well there. I remember some years ago being struck with the healthy appearance the trees had on a Peach wall of great length, and 15 or 16 feet high, there being scarcely a square foot from bottom to top that was not covered with healthy, fine, bearing wood, and loaded with fruit, which in fine seasons I should venture to say arrived at a degree of excellence unknown in those grown under glass. In dull, adverse seasons, perhaps, this might not be the case; but from the healthy, fine, bearing condition of the whole it was evident that in general all went on well. There are, besides, many other gardens of note near Liverpool; but I confine my observations to those which I have visited, and in the absence of accurate knowledge of the others must ask the tourist to again take the rail northward, and near Wigan is Haigh Hall, the seat of the Earl of Crawford and Balcarres, a place possessing many fine features, the abundance of coal in the neighbourhood favouring forcing of all kinds. Beyond Haigh Hall, however, the country becomes less inviting, although as a coal country it has not the desolate appearance of some districts in South Staffordshire. Near Ormskirk is also the seat of Lord Skelmersdale, Latham House, a noble mansion of the early part of the last century, embowered amongst trees and scenery which neither railways nor manufactories have yet invaded. I should, however, when at Knowsley, and consequently on the line of one of the first passenger railways made in England, have conveyed the visitor to Worsley, some ten miles still nearer Manchester, the seat of the Earl of Ellesmere. The mansion is beautifully situated on an eminence, has a superb flower garden in the embroidered style on its south side, with terraces, slopes, and other fitting appendages, surrounded with extensive grounds of a less formal character. As we are approaching Manchester, which might with as great a claim as Liverpool become the centre of a district full of gardening attraction, I must take leave of the tourist at the latter place, so far as personal acquaintance with gardens of importance is concerned, and refer him to some other guide. I am told that Lord Sefton's garden is fine, and that there are several others in the suburbs of Liverpool, all deserving of attention.

Assuming the traveller to prefer a midland instead of a north-western route, if he were to make Derby his headquarters, he might from this place very conveniently visit Elvaston Castle, the seat of the Earl of Harrington, and there see the extensive collection of Conifers with the long avenue, as well as the curved and formal line of shrubs and trees cut into every fanciful shape. It would, however, be advisable to make sure that Elvaston was open to visitors before venturing so far, as in years gone by it was closed against the public. It has, however, lost much of its importance since the public have had more chances of visiting it; and the Japanese or Chinese taste, which it exemplifies in its formal and often quaintly-cut shrubs and trees, has not taken well with the English public: nevertheless, it is well worth a visit. Borrowash, half a dozen miles or so from Derby, is a station very handy to it. The neighbourhood is flat and uninteresting, and all the eminences are artificial; even the water is artificially formed. On the opposite side of Derby, and at double the distance of the last-named place, is Chatsworth, which is reached by rail. I need not descant on this fine place further than to say that it will well reward the visitor. There are also, I am told, some other fine places in the neighbourhood.

Conducting the tourist back again to Derby, I must ask him to extend his journey on the North Staffordshire Railway to Alton Towers, a station of that name being close to that celebrated place. Here he will see levels and formality disregarded, and rugged mountain scenery blended with the softening touch of dressed ground, and the whole on a magnificent scale. From Alton Towers he might proceed to another centre of inspection further westward, where he could reach Trentham, which is on a loop of the same line of railway. He might, after that, make his way to Manchester if he liked, and the places of importance within easy reach of that city are too numerous to be mentioned here.

As I have already extended this article to such a length, I must leave the other places of note that are within easy distances of each other until a more fitting opportunity, advising, at the same time, the intending tourist to make himself still further acquainted with the places he purposes to visit ere he start, and, if possible, to ascertain if the place be open to visitors. Generally speaking, gardeners from a distance are admitted when the general public would be refused, but it is better in all cases to insure this before an unpleasant disappointment occurs; for, although it may seem harsh to turn a visitor away from the gates, the privacy of the owner ought to be the first object of consideration. The extreme liberality of some noble proprietors of mansions and gardens in throwing them open to the public on certain occasions ought to entitle them to more undisturbed privacy at other times; while those opposed to the admission of large bodies of visitors into their grounds, have, nevertheless, no doubt good reasons for being so. A note beforehand from a gardener of standing will often pave the way to an easy admission, and very often bring about an agreeable introduction.—J. ROBSON.

ORCHARD-HOUSES.

HAVING been much interested by reading the discussion on this subject in your Journal, I determined to see the orchard-houses of Mr. Rivers and Mr. Pearson, and must say they exceeded my expectations, and I am quite convinced their usefulness is an established fact. Having read so much about the difficulty of growing Apricots in houses, imagine my surprise at seeing, at Mr. Rivers's, scores of large trees literally covered with Apricots—and such Apricots! bright golden fruit, no Oranges could be more beautiful, and as to the taste, my mouth waters at the recollection, I had no idea they could be so improved. Some of the Peach trees at Chilwell are most beautiful, perfect cones, 7 or 8 feet in height, with leaves longer than my hand.

One thing struck me much at both places—there was plenty of fruit, luxuriant foliage, and hardly a trace of red spider to be seen, the trees being of large size, many of them seven to ten years in pots. There does not appear to be any great difference in their management at the two places; Mr. Pearson has built very handsome houses, those of Mr. Rivers are of a cheaper description, but the trees are all that could be wished. It appears to me that care in watering, and liberal feeding, are the great secrets of success. The under side of the foliage was syringed twice a-day, the soil, when requiring water, being well soaked to the bottom of the pots. Each pot was covered a couple of inches with a mixture of horse-droppings and malt dust, this Mr. Pearson called Mr. Rivers's mixture, and he said it was superior to the manure water he recommends in his own book, and from what I saw I have no doubt of its value; it never stops the water, the dark foliage of the trees shows how it is enjoyed by Peaches, and wherever it has been applied to Vines strong white roots have run through it in all directions.

Last, not least, much was said about stopping the shoots. Up to the end of July every shoot, particularly on the upper part of the trees, was stopped, so that the trees are full of short stiff branches. This I feel sure is the main point in Apricot culture, as the crop appeared in exact proportion to the sturdy nature of the shoots; long thin branches either drop their fruit or it is small and poor.

Those who visit these establishments will see by the large number of trees cultivated for sale that the orchard-house is not looked upon as a mere fashion of the day, my own impression is that it is only in its infancy. The great reason

the system has not made more progress is the want of men who understand it, at least so it appears to me. Men of little education require to see a thing done to be able to do it afterwards, and without practice and experience make poor gardeners and farmers, and even the best-read man who is quite up in theory, generally pays at first for his want of practice.

Another thing struck me very much during my pleasant visit to these places, and that was, that the fruitfulness of the trees appeared to be greatly increased by age. From what I saw I should not expect much from young trees, nor should I fear them dying or being worn out by age, the oldest trees were in every respect the best.—A. B.

CUCUMBER DISEASE.

A CORRESPONDENT sends the following as a remedy; and we append Mr. Fish's remarks, which will prove interesting to our readers:—“A red-hot brick placed in a Cucumber-frame, and sprinkled over with sulphur and water, produces a vapour which destroys the disease. This remedy has often been tried by an experienced gardener with the greatest success.”

[Your remedy—a red-hot brick sprinkled over with sulphur and water—whatever effect it had on the disease, would, we think, be fatal to every leaf that came under its influence. In a large lofty house, and where the fumes and vapour would be pretty well dispersed before reaching the foliage, the danger might be lessened; but it is a cure we would not like to try unless where cure or kill was a matter of but little moment. A sulphurous atmosphere has little effect in curing the diseases of the Cucumber with which we are acquainted, and we are left in doubt what your disease is.

If mildew were the evil the sulphurous vapour would do some good; but then that would be best applied by painting the walls exposed to the sun with sulphur, or sulphur and soft soap, or in heating a metal vessel to 150°, and then painting the outside with sulphur; or, better still, painting the outside first, placing sulphur in the shape of thick paste in the vessel, and then adding water of the temperature stated above. Every bit of sulphur that touches a red-hot brick carries destruction to everything having vegetable life that the vapour reaches. It would be less dangerous in a large place, because the vapour would be more dispersed and cooled before reaching the foliage. We say decidedly that our practice in this respect is thoroughly opposed to that of the experienced gardener. We, too, have burned sulphur in pits and houses, but it was after the leaves were all fallen from deciduous plants, as the Vine, and the wood was too firm and hard to be injured. We would never think for a moment of exposing an evergreen or a growing plant to such an influence. We know myriads of cases of ruin thus produced. Some years ago one of the best old practical gardeners of the day destroyed numbers of plants in a conservatory by giving them sulphur vapour too hot. He tried tobacco on insects; and as it did not act quickly enough in destroying the numerous shoals of successive broods on some Cinerarias, he put a bit of sulphur along with the tobacco, and as long as he lived he used every now and then to blame his carelessness and want of consideration, and all the more because many years before he knew all about what burning sulphur would do. We have hesitated even to recommend mixing sulphur with quicklime and water in a close atmosphere for this purpose, for fear that the sulphur would be too much heated, and because the lime from limestone will give out so much more heat than the lime formed by burning chalk. For mildew the sulphur may be spread, or rather dusted fine, on the foliage, and the labour may be lessened by removing all the foliage most affected. When leaves are pretty well dusted over with mildew it is waste labour to attempt to restore them. It should be treated as soon as the first trace appears; but, as stated above, for the diseases of gummy excretion, or brown spot on the leaf, we have found no remedy in sulphur. For these, as stated in “Doings of the Last Week,” the only remedies hitherto found are fresh air, not too high a temperature, fresh soil, and repeated planting with young healthy plants. Some of the once

most successful growers of the day, and for a quarter of a century past at least, know not the cause of the disease, and know as little how to conquer it. Whenever it appears fresh planting is the great remedy.]

FIG TREE THROWING ITS FRUIT.

“A LADY” has a Fig tree which has been planted in her garden for about fifteen or sixteen years, and for the last few years all the young Figs have fallen off, with, perhaps, one or two exceptions. Imagining that this might be caused by a draught of cold wind, to which it was exposed, her gardener, last year, trained it, without removing it, under a projecting roof, and upon a wall in an unexceptionable situation, where it was exposed to the south and to the west. As it had been necessarily much cut-in, nothing was expected of it last season. This year it produced a very fair proportion of Figs, but many have already fallen off, some having nearly attained their full size; and all the rest will no doubt fall off also, as they are turning yellow. The lady regrets that she cannot remember the name of the Fig. Its fruit is large and brown, and it was considered a first-rate kind.

[The Brown Turkey, or Lee’s Perpetual, is one of the best of Figs for bearing freely. We question, however, if this be the kind you have, as the fruit is not so very large. Your description would, perhaps, apply better to the Brunswick, a good Fig, but not such a free bearer as the Brown Turkey. We are left in a little doubt as to the cause of the fruit falling off, because you do not say whether the wood of the tree is extra luxuriant, or rather somewhat stunted. In the former case extra luxuriance will sometimes cause the fruit to fall; and the best temporary palliative for this is ringing the shoots below the fruit, slipping out about the twelfth-of-an-inch ring all round the shoot, which will soon fill up. The object is to lessen extra luxuriance, and keep the elaborated sap more in the vicinity of the fruit. The most effectual remedy is to lift, replant, or root-prune in autumn, drain, keep dryish in winter, and give plenty of water after the fruit appears. If your tree is not extra luxuriant, the dropping of the fruit for successive years leads us to the opposite conclusion—that the fruit drops for want of sufficient moisture at the roots.

Figs grown in pots, if allowed to become dry at the roots when the fruit is swelling, are almost sure to drop more or less, and after each such case of dryness. We have known Fig trees, moderately luxuriant, out of doors, drop their fruit from over-dryness at the roots. When the fruit is swelling they will drink almost like an aquatic, but the moisture must not be stagnant.

Were we to plant Fig trees out of doors, we would secure good drainage; a bottom for the border, through which the roots would not penetrate, or be tempted to go—some 6 or 8 inches of open rubble all over, then a depth of from 12 to 15 inches of strong loamy soil, and a width of border of from 3 to 4 feet, beyond which the roots should not be able to go. Here the wood would grow robust and be well ripened, and water could be given in summer without any danger of stagnant moisture. Some years ago we described a large Fig tree, most of it possessing short stunted shoots bristling with fruit as closely as they could be, the nodes being so close to each other. One part of the tree produced luxuriant wood but little fruit, and on a close examination we found the large limbs of the productive part had the bark all gnawed near their base with mice. In fresh planting we would wish to attain the same beneficial result without having to resort to ringing, root-pruning, or the nibbling of the mice.

Without some such precautions as to the state of the roots and moisture, the Fig tree will often be an uncertain bearer out of doors. We have two trees that generally bear well. This season the fruit is dropping a little, owing to dryness at the roots and to a luxuriance produced by the roots going deeper than they ought to do. We cannot do anything to them without much labour; and as we have plenty of others we do not set great value on them, and generally get as much fruit as we want. We neutralise the luxuriance by keeping the shoots well sunned in summer, and not too many of them. In a neighbouring place a gen-

tlemen was celebrated for Figs growing against the sunny side of his stables. He allowed no one to touch them but himself, and they scarcely ever saw knife, or shred, or nail, the branches hanging somewhat from the wall; but the roots had little to grow in, and the wood, therefore, was short, and plump, and stubby, and the plants did moderately well.—R. F.]

TURF SOIL.

THERE are few requisites for a garden so troublesome to procure as turf soil, unless a man has an estate of his own, and even where there is plenty of grass land the gardener is not always permitted to cut turf. I know that the want of this supposed essential material is severely felt by many persons. There can be no doubt that the man who can procure soil of various qualities, light sandy turf, turf from a loamy pasture, and turf from a rich strong clay, who has ready to his hand a good heap of peat, another of decayed leaves, and a quantity of cocoa-nut fibre, has a great advantage over a man who with difficulty prepares a compost, or procures a soil for his trees. I would not for a moment produce the impression that it is a matter of minor importance to have good soils ready at hand, but where the thing we want cannot be had, a good substitute is a desideratum.

Having heard of Mr. Garsides's man, at Worksop, being very successful as a grower and exhibitor of fruit, I went to see his practice. Pines, Grapes, and plants, were all well grown, indeed it is not often they are seen in better condition, and yet not a particle of turf soil is used in the garden. The gardener told me turf was very difficult to procure, and he asked himself whether it was necessary. "What are the advantages of turf? It is fresh soil to the plants I want to grow: so is any soil which has not grown those plants before. It is full of grass roots, and less compact than ordinary soil: this mechanical condition ought to be easily imitated. It is full of vegetable matter—that can be easily supplied."

The result of this was, he had a quantity of fresh stable litter, just as it left the horses, chopped up and mixed with garden soil, and in this every plant and tree, except such as require peat soil, was growing luxuriantly.—J. R. PEARSON, Chilwell.

TODMORDEN BOTANICAL SOCIETY.

MEETING, AUGUST 1st, 1864.—E. Binns, Esq., in the chair. Mr. S. King, of Laneshore, Luddenden-Foot, was elected an associate member. Mr. J. Law exhibited fronds of beautiful varieties of the Lady Fern, gathered during the past month in Langfield. One of them is regarded as quite a new form, and is proposed to be named *Athyrium filix-femina brevipinnulum*, all the pinnules, except the basal, being rounded and shortened very remarkably. Another filical novelty was reported in the hands of the members—*Athyrium filix-femina curtum*, from Windermere.

Letters were read from the North Devon excursion party, with accounts of their progress, and a long list of rare plants already found. A long and highly interesting communication was also read from Mr. W. Hobson, of Philadelphia, an associate of the Society. Mr. Hobson gives in a journal form, an account of a botanical tour made by him through some portions of Pennsylvania during June and July last. His success was very considerable, as will be seen by the list of plants given below. Mr. Hobson, describes the heat as having been quite unusual, the thermometer having indicated 100° in the shade for three consecutive days. Among the plants collected by Mr. Hobson, were the rare *Polyodium incanum*, the rare, highly-curious, and very minute *Schizaea pusilla* (in considerable quantity), *Pteris (Platyloma) atropurpurea*, so much prized of Fern-lovers, and so seldom found in collections (many scores of plants), the lively *Cheilanthes (Nothochlena) vestita* (in quantity), *Botrychium limparioides* (*fumariooides*), *B. obliquum*, and *B. virginicum*, *Asplenium angustifolium*, *Lycopodium inundatum* (var. *Bigelovii*), *Lycopodium rupestre*, *L. complanatum*, &c.; among *Phænogams*, *Anemone thalictroides* (in quantity) *Arum triphyllum*, *Chimaphila maculata*, *C. corymbosa*, *Drosera filiformis*, *Hypoxis erecta*, *Sarracenia purpurea*, *Orchis spectabilis*, several species of *Cypripedium*,

six species of *Viola*, including *V. lanceolata*, and *V. sagittata*, *Goodyera pubescens*, &c. It is expected that at the next meeting of the Society Mr. Hobson will attend, to report his experiences in person.

The Honorary Secretary announced the recent discovery in North Wales by Mr. Bruce Findley (Botanic Gardens, Manchester), of an immense number of plants of *Asplenium trichomanes ramosum*, many of them very closely approaching *A. t. cristatum*, and several rare varieties of *Blechnum spicant*. Mr. Findley may be congratulated on his good fortune. A box of North American fossils, the gift to the Society of Mr. F. Hartley, Alton, Illinois, was announced as on its way, by favour of Mr. Hobson.

CULTIVATION OF THE MELON.

(Continued from page 110.)

A PIT without means of lining, or applying heat after planting, is represented in fig. 4. In this case the pit is

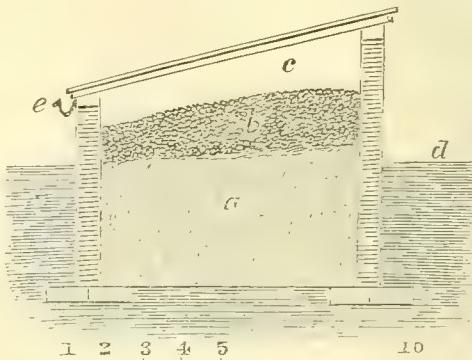

Fig. 4.

filled quite up to the rafters with prepared fermenting materials beaten well down, and trodden firmly, so as to prevent the material of which the bed is composed falling too low, and causing the plants to be at too great a distance from the light. Such pits are very useful in winter and spring for Endive, Lettuce, early Potatoes, &c., and a crop of Melons may be had after these, by planting strong plants in May, or at the latest by the beginning of June. The fermenting materials give the plants a start, and sun heat carefully husbanded must be made to do the rest of the work. The bed is soiled, and otherwise treated as described for fig. 3.

The figure shows the state of the pit about a month after planting; *a* is the bed of fermenting materials; *b*, soil over it; *c*, open space for the plants to grow in; *d*, the ground level; and *e*, the spout to carry off the rain water, which may be collected in an old barrel sunk in the ground.

The flued-pit represented in fig. 5, is chiefly employed for growing late Melons, and when not in use for that purpose is utilised in a variety of ways. There is a space for a hotbed (*a*) to be formed of dung, leaves, or other fermenting

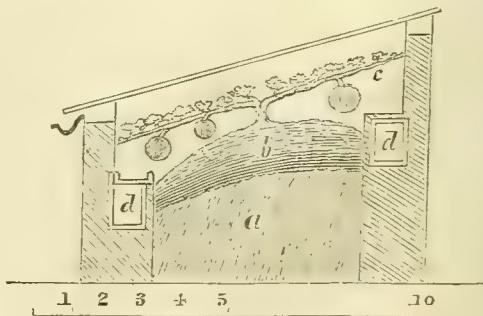

Fig. 5.

materials; *b*, shows the soil above it. There are sometimes moveable trellises for training the plants on, as at *c*, *d*, *d*,

are flues, the hot air passing along one end and the front first, and then along the back. Melons to afford a late crop may be planted as late as the beginning of July, and if they set their fruit in August they may be ripened by fire heat, no more of that being employed than is necessary. In this way Melons of moderate flavour are obtained in October, and up to Christmas, but not equal to those ripened in summer, when there is a longer continuance and greater intensity of light and sun heat.

Fig. 6 is what may be termed an open pit, being nothing more than earth dug out a yard deep, and a single brick wall, *a*, run round the outside; *b* consists of wood faggots

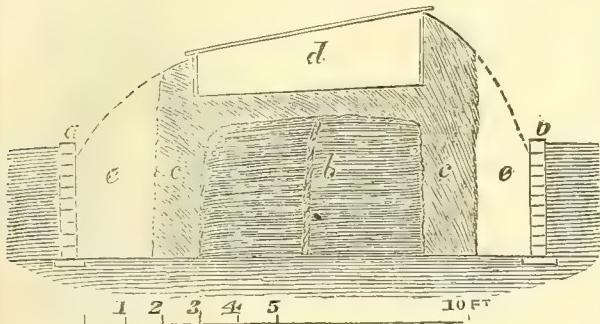

Fig. 6.

piled up to a height of 3 feet, and round them hot dung, leaves, or other fermenting materials are placed at *c c*, pressed firmly, and carried up to a height of 5 feet, so that the dung may be 2 feet higher than the wood faggots, and partly at the sides, and partly above them, as in the figure, only the bed there shown a foot too low, in order to represent the appearance when the frame is put on. *d* is an ordinary garden frame placed upon the bed thus made.

By this system the violent heating at first of a dung-bed is obviated, and a saving of material effected; by filling the open spaces, *e e* (first the front, and in ten days or so afterwards the back of the frame), with grass mowings, weeds, or old rubbish of any kind, additional heat is obtained, and it readily passes among the faggots *b*. When it becomes necessary to have a renewal of heat, it is only necessary to turn over *e* and *c*, moistening them if dry, and adding a little fresh material if at hand. In a week or ten days the opposite lining may be served in a like manner. The utility of a pit of this kind will be apparent, for it not only presents a place for rubbish, but is a means of turning its decomposition to advantage, whilst its value as a manure is much enhanced by the process.—G. ABBEY.

(To be continued.)

COOLING WATER IN HOT WEATHER.

It may seem needless to ask for scientific means for making and keeping water cool, just when the late fall of rain will probably bring a cooler atmosphere naturally. Nevertheless, I apply to you to know whether there is not some comparatively easy way of causing a bottle of water to become almost iced by evaporation. If so, why can I not succeed? I have tried the red porous earthenware jugs, but they give a disagreeable taste to the water; then a machine something like a hat, but the butter seemed nearly as liquid when taken out as when put in. Lately, I tried hanging a glass bottle in the sun in a thorough draught with a wet worsted stocking drawn over it, and even during the late hot weather we have had plenty of wind near the river where I live, but the water was little if at all cooler in consequence.

I have long been convinced that a fortune might be made by some person ingenious enough to make a simple, inexpensive, and not bulky machine for storing ice. Ordinary refrigerators cost £4, and take up far too much room for small houses.

Wenham ice may be cheap enough in London, but in my neighbourhood it can only be had at a cost of 3d. or 4d. daily, and then only for one meal, as there are no means of

keeping it between meals, besides the troublesome necessity of ordering it beforehand. And yet what a comfort it would be to invalids, and, indeed, to everybody to have cold things to eat and drink in summer!

We have a sort of out-house room which has been condemned as too damp for any one to sleep in, and the floor is taken up. Could not this be turned into an ice or snow-house by draining away the meltings? It is rather below the surface of the ground, but has two cross windows, east and north, and a chimney, so it ought not to be damp. Can you help me either for the future or for the present?—H. H. Y.

[We heartily wish some of our scientific readers would try and help our correspondent and oblige us at the same time. Personally we know little more of the matter than was stated in a late republished article on ice-houses, &c. A thick deal box with a secure lid would keep ice a considerable time, and these any carpenter might make to order. Our whole experience as to cooling water inside of bottles, glassware and earthenware, is opposed to the results you have found. We one time had a sort of passion for cool water in summer. We had the water from a running brook, put it into common wine-bottles, pulled a woollen stocking over them, and suspended them full in the sun, with a large pail fixed above them from which two pieces of wool list depended over each stocking, just preventing the stocking getting dry. Had we not stopped this pleasant practice of quaffing large quantities of this cooled water, we should not have been alive to write these notes. We got in a bad way, and a friendly doctor told us that these cooling draughts taken too frequently give a terrible check to the circulation of some persons, and we believe from our own experience that he was perfectly right.

We know no reason why you should not turn your spare outhouse into an ice-house or snow-house, but we do not think you will succeed unless you do away with the windows, obtain a double door, and either have a double wall and roof, or cover the whole outside with a coating of a foot of straw neatly laid on. Then with drainage we believe the ice would keep as well in an outhouse as in an ice-well or ice-house. In fact, in the late article, an ice-house is described as wholly above ground. Your outhouse would be of little use if the sun shone, or the wind played on a common roof, or a common wall, and, of course, the windows would soon settle all.]

BELFAST ROYAL BOTANIC GARDENS.—At a very numerously attended meeting of the Directors on Wednesday, the 3rd inst., Mr. William Hooker Ferguson was appointed Curator, as successor to his late lamented father, who so long and worthily filled that situation. It is very much to the credit of Mr. William Hooker Ferguson, and speaks strongly for his abilities and pleasing disposition that the Directors were unanimous, and that the letters of recommendation and certificates read from Sir William Hooker, Mr. Smith (the late Curator of the Royal Gardens, Kew), &c., were highly satisfactory. A letter was read from one of the Directors, who had been waited on with a proposal that a deputation from the local nurserymen and gardeners should attend on the Directors to express a wish that Mr. Ferguson would be appointed. This is a strong evidence of the good feeling entertained towards him; and with every good supporter of the gardens the hope is strong that under his management and with increased finances they will go on and prosper.

WORK FOR THE WEEK.

KITCHEN GARDEN.

CONTINUE to plant out winter and spring vegetables wherever there is room. *Cabbages*, another sowing of the different kinds may be made for spring planting, and like wise of hardy *Cos* and *Cabbage Lettuces*, selecting a similar spot for the seed-beds as recommended for *Cauliflower* *Cauliflowers*, towards the end of the week the principal spring crop of *Cauliflower* and *Walcheren Broccoli* should be sown. Sow thinly in an open place and not on too rich a soil, or the plants will become gross and less capable of standing the winter. *Endive*, plant out; where the ground is wet this crop should be planted on raised slopes facing the south,

to prevent damping in wet weather. This really valuable winter vegetable should find its way into every garden for culinary use, independent of its value as a salad plant. Onions, pull them up directly they show indications of ripening, and expose the bulbs to the sun to ripen them. Parsley, thin out and cut down a portion of the spring-sown, that a fresh growth may be made before the winter. A portion of the thinnings should be potted in twelve-inch pots for removing to frames in the winter. Radish, sow succession crops of the white and red Turnip Radish. Shallots, take up, and also Garlic for drying. As soon as a sufficient quantity of droppings is ready, proceed to make a bed for Mushrooms.

FRUIT GARDEN.

The present is one of the most important periods of the whole year as to giving due attention to fruit trees. The autumn will soon approach, the solar light become much diminished, and the soil will be perhaps saturated by the autumn rains: it will then be too late to talk of the benefits of light to trained fruit trees. All tender fruit trees which are trained will now be benefited by stopping the growing shoots. Any amount of control may be exercised over the roots by such means. Of what use is the excitement of so late a root-action as we frequently see encouraged by means of enriched soils and the neglect of stopping? In looking over Peaches and Nectarines it will be found that many of the shoots which were deemed necessary and nailed in for succeeding crops will begin to overlap each other; many of these are stopped at this period. Pears, too, whatever superfluous shoots may have been retained, with the idea of preventing the blossom of next year from breaking, should now be well shortened back sufficiently to admit the sun's rays with freedom. The stumps cut back (each carrying three or four efficient leaves), will assist in producing elaborated matter both to feed the fruit and to invigorate the embryo blossom-buds, now actively engaged in depositing food for a healthy development in the ensuing spring.

FLOWER GARDEN.

Hollyhocks, Dahlias, and herbaceous plants must be made safe from the effects of high winds by securely fastening them to their supports. The like attention should be paid to climbing plants against walls and trellises, standard Roses, &c. There is an appearance of negligence when plants are seen blown about by the wind, which should by all means be avoided. Remove daily dead leaves, withered blooms, and litter, and frequently sweep and mow grass, that a clean and well-kept appearance may be preserved. The general pruning of evergreen shrubs should now take place, reducing straggling growth within proper bounds, but avoid giving them anything of a formal character; the object is to assist not deform nature, and the general characteristics of each plant should be as much as possible preserved. The case is different in pruning shrubs used as architectural embellishments, which will require trimming into the precise figure wanted. At this season many florists divide and repot their Auriculas and Polyanthus, that both young and old plants may be established before winter. Avoid exciting composts, stimulants are only applied when the plants are growing. Take care that newly-planted beds of Pinks and Pansies do not suffer from drought.

GREENHOUSE AND CONSERVATORY.

The usual quantity for a season's supply of the soil used in potting, should be laid in as soon as possible, and before the ground is sodden with the autumn rains, for even turfey soil should not be carted and stacked up when saturated with water. The soil should be neatly put up in narrow ridges so as to be safe from wet, and it should be exposed as much as possible to the action of the air. As success in plant-growing very much depends upon having suitable soil for potting, no trouble or expense that may be necessary to procure this should be spared, when well-grown specimens are expected. Loam of moderately good quality may be obtained in most neighbourhoods; but good peat is not obtained in many localities. This is absolutely necessary, however, for the growth of choice hardwooded plants, and should be procured at the proper season, so as to have it in a fit state for use when wanted. Stove plants flowering in the conservatory will require attention to prevent their being injured by damp, especially Achimenes, and Clerodendrons, which should be gone over every day in cloudy

weather, carefully picking off decayed flowers, &c. Any of the twiners on the roof which have done flowering may be thinned out, so as to prevent shading the house too much, for after this season permanent shade should be avoided as much as possible. In mixed greenhouses look well after winter-flowering plants of a common character, such as Cinerarias, Verbenas, scarlet Pelargoniums, Heliotropes, Roses, &c. Cinerarias must now be potted off, whether from seed or from suckers; Chinese Primroses also, giving the last shift to those intended to bloom in November and December. Scarlet Pelargoniums to bloom well should be rather pot-bound.

STOVE.

Continue to top up the late growth of Orchids, and to keep the plants at the warm end of the house. Give air liberally in the early part of the day, and on very fine mornings syringe occasionally the whole of the stock. A little fire heat must be kept up, if only to insure a proper circulation of air.

COLD PITS.

Young stock intended to flower next season should be exposed to the midday sun, in order to ripen the wood, taking care not to do this so rashly as to injure the foliage. This, however, will only be proper in the case of such things as have already made plenty of young wood, but it is advisable after this season to anticipate the approach of winter, and to use every possible means to forward the growth of valuable hardwooded plants in order that it may be somewhat firm and able to resist damp.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

FOR calender references of what should be done, we beg our readers to refer to Mr. Keane's judicious advice for the last, and no doubt also for the present week. We have little to say, because we have done nothing but help to keep things going on as they were, being but too glad if they were not going backward. On Tuesday morning and during the day we had a nice refreshing rain, which though it did not do much to moisten the earth, cleaned the foliage, and swelled out the stems. We should have liked more rain, as it scarcely told upon our reservoirs, but we were thankful for what did come. The whole appearance of vegetation was changed as if by magic. The birds sang with their sweetest notes, and the blackbirds and thrushes for some dozen or twenty hours, showed by their comparative absence that they could be independent of our fruit, and of ourselves likewise. Swallows that a few hours previously were soaring almost out of sight, actually came on the lawn to enjoy the damp herbage, and straddled across it in search of insects, much as a water wagtail would have done. We felt that we could have beaten a hulking fellow lately, for ill-using some wagtails, one of our best friends, and also one of the most beautiful of British birds. We have noticed of late great numbers of swallows clustering on the roofs of conservatories, the ridges of houses, &c., as they generally do in the end of September. We presume the excessive drought has lessened the supply of insects for food. On Wednesday the morning came cool and chilly, but the rising barometer and the brightening sun told us the rain was over, and inculcated the necessity of being equally careful as to water. Since then the fierce sun and scorching wind has evaporated most of the moisture that the dried earth drank in so pleasantly on Tuesday. We can only hope that the drought this time will be of shorter continuance.

If no rain fall winter Onions and Spinach should be sown, and left for the rain to bring them up. It is of less use sowing Turnips, Radishes, and Lettuces, unless they can be watered or shaded, as the hungry birds would have all the seed before it came above ground. Lettuces and Endive should be planted out where there is any water to give them. We have, as yet, a good supply of the former from shady places. We have given additional shading by branches of trees to our Celery, as we could not water, and mulched the sides of the rows of Peas to help to keep them green. Cleared off some Peas that had ripened before their allotted time, and had left others standing, though not attractive by their partly withered appearance, because they acted as a

shade to crops of Cauliflower between them. Kept the Dutch hoe going amongst most growing crops, less for the purpose of killing any young weeds than to secure a fresh-stirred surface to keep heat out and moisture in.

FRUIT GARDEN.

Strawberries in pots had the incipient runners taken off and the pots attended to in watering as well as we could. Gave a soaking of sewage water to the late Vine-border, as the berries were beginning to colour too soon from the heat and the dryness at the roots. Should have liked to have done the same to Peaches and Apricots out of doors, as some of the latter are dropping before they are ripe from dryness. Have great difficulty in getting a little clean water to syringe the trees in the orchard-house; and the water-scarcity tells much against trees in pots heavily laden. The rains of Tuesday having washed most of the sprinkling of whitened water from the glass, we renewed it again on Thursday, to arrest rapid evaporation. The fruit is ripening faster than we wished, and faster than it would have done had there been plenty of water to give. With abundance of water we would not have shaded the glass. It has now become our last means of safety. We have also slightly sprinkled the glass of our late viney with a similar object. This would have been still more necessary if we had removed laterals freely. We had some Grapes sent us to look at the other day which had been parched into a brick-red colour by a too free removal of laterals and leaves, and, perhaps, keeping the enclosed atmosphere rather close and warm, the bunches being thus exposed unprotected to the fierce sun. In some of the hottest days we sprinkled the floors of viney with slightly from a syringe, just to moisten the air a little. The sprinkling with whitened water on the glass is done by colouring, say four gallons of water with as much as a small walnut or hazel nut of whitening. A large space may be dusted from the syringe in a few minutes, and if not thick enough the dose may be repeated. The first shower will take it off, and that just suits this temporary shading. In hot windy days we can thus do with less air, and, therefore, the plants are less dried, a matter of importance only where water is scarce.

Some fruit trees that were showing signs of distress we have mulched round as a substitute for watering. In such continued dryness, and no means of watering, the plants are induced to send their rootlets down in search of moisture, and if this is not remedied afterwards by replanting or root-pruning, there will be a tendency to produce luxuriant unripened, instead of short stumpy wood. Any means that will keep or entice the roots near the surface will thus be of importance for securing fruitfulness.

Went over most of the trees in orchard-house, shortening, nipping, and removing extra shoots, and cutting in half, or taking away altogether any leaves that shaded the fruit too much, as though Grapes are better of a little leaf shade, Peaches, Plums, and stone fruit generally are best when the fruit is pretty well exposed when ripening. Hoed all fruit-borders to keep an open surface. Run the rake along any open spaces in the orchard-house for a similar purpose, and to promote neatness, as all places under glass ought to be very neat and clean. Weeds or filth there are next to unpardonable, even though cleanliness were not as essential to the health of plants, as to the well-doing of animals.

Went over most of the dwarf fruit trees out of doors, gave them a second stopping, and thinned the shoots. Apples and Pears that were stopped early, are, in many cases, showing fine prominent buds on the parts stopped, and the short fresh growth has been again stopped, which will further help these buds farther back. It is a good plan to do the greater part of the pruning of fruit trees now, and to leave no more wood than will be necessary next season, so that more air and sun may act on that which is left. A little finishing up, and removing exhausted wood, but which is now bearing, as in the case of Peaches, &c., should be the chief things reserved for winter and spring pruning.

We have been obliged to whiten all the glass of frames and pits, where Cucumbers, Melons, and even plants where growing, in order to lessen as much as possible the necessity for watering. This also rendered less air necessary. In such weather, Melons, &c., grown in hotbeds will generally need

less water than those in places heated by hot water. The surface soil should be kept open to lessen evaporation.

ORNAMENTAL DEPARTMENT.

Kept the floors of stove-house as damp as we could. Our washed gravel above the tiles of the floor has greatly helped us here. Gave a little manure water to Stanhopeas, which were blooming freely, to increase the size of the blooms, and kept potting young stock of Euphorbias, Poinsettias, &c. Fresh regulated conservatory, and took in more Begonias, Coleus, and Scarlet Geraniums. Epacris, and winter Heaths should now have more sun to ripen the wood, but the pots had better be protected from the fierceness of the sun's rays, as, if the pots are full of roots, these are apt to be burned when close to the sides of the pot. Care should also be taken to moisten the whole ball when watering. Even our favourite resource of ringing the sides of the pot will not prove an unerring guide in this respect. If watering has gone on for some time, and the ball has not been thoroughly moistened to the centre, the dry part there will keep on increasing until it will at last repel water like the feathers on a duck's wing, and what water is given will under these circumstances chiefly escape by the sides of the pot, and if damp there, on ringing it, the pot will emit a dull sound as if all the ball were wet. The weight of the pot will be the next test; but in all cases of doubt it is best to perforate the centre of the ball with a small wire, and then water, or plunge the pot for an hour over the brim in a pail of water. Many a fine plant has thus been saved that otherwise would have dwindled away until it went to the rubbish-heap. When flagging in an established plant takes place, notwithstanding repeated waterings, it may almost be certain that the ball is dry at the centre. We say established advisedly, because young plants will often flag when wet enough, because the roots have not had time to supply moisture to meet the demands of evaporation. A syringing or a shading in their case will often be of more importance than watering at the roots. But in the case of old-established plants which common watering fails to aid, the placing them in a tub of water for half an hour or more will often prove a sovereign remedy.

Removed lots of Gloxinias, Achimenes, &c., to pits, frames, and sheds to ripen their tubers and bulbs, and gave all the light and heat possible without artificial heat to the Amaryllis tribe for a similar purpose, and plenty of water until the leaves began to change colour. Free growth in summer, and rest in autumn and winter, are what suit most of these beautiful hybrids.

In contradistinction to the general run of plants, most of the succulent plants, and especially the larger Cacti, can now scarcely have too much sun, and too little water, provided the shoots and stems are just kept plump. The best place for these in August and September, is the south front of a wall or fence, where the sun will play freely on them, and if rains are anticipated it would be well to have tiles or slates placed over the pots, to throw heavy rains off them. Little water at the roots will now be wanted, provided the stems do not shrivel, and then next spring and summer there will be sure to be abundance of bloom. Such succulents are pretty well dried up in the dry season in their tropical or next to tropical homes, and the natural conditions in which they bloom most profusely present us with the key to their successful culture.

We have begun propagating for next season, commencing with Verbenas. For reasons already stated, we will not do much with Geraniums until a week or two have passed. These Verbenas, owing to the great heat, and the little or no watering they have received, have some fly and thrips on them, and the cuttings when made were well washed, by pulling them repeatedly through a wash made of 4 ozs. of tobacco, and as much Quassia chips boiled in a gallon of water, and then the water strained off. The cuttings were allowed to lie in heaps after this washing for half an hour or so, and then were washed again in a vessel of clear water, and shortly afterwards dibbed into pots. We hope by this means to escape future trouble, as Verbenas with thrips or fly on them are a constant source of annoyance, and a little trouble now may save no end of work afterwards. The cutting-pots along with Petunias, &c., are placed on the ground, and covered by a frame, with the high side to the

south. We shall be sorry to give them any artificial heat. It may be wanted with late-struck plants.

The rain of Tuesday just saved our flower-beds for a little longer display. As stated last week, we never saw Geraniums much better, the drought, as yet, has affected them but little. Calceolarias that were never finer are again showing signs of distress, and we presume we shall be able to give them no help, as water for cattle, let alone plants, is now becoming a serious consideration. We find there was a mistake in printing last week, when the lawn is spoken of as getting "green." It should have been "brown." But for this brownness we question if the principal parts of the flower garden ever looked better. Visitors have expressed their astonishment at such masses of bloom in such drought, and with little or no watering. We cannot expect it to last much longer, as we fear anything like watering is entirely out of the question. Already Calceolarias are drooping, and we fear that dwarf and tall Dahlias, independently of mulching, must go to the wall, and, unless a soaking rain comes, we must be satisfied if we can save the roots. We mention these facts because already gardeners situated as we are are being found fault with because vegetables are becoming hard, and flower-beds decaying, and fruit falling before it comes to perfection. If water cannot be had, and all other palliatives are taken to lessen the consequent evils, we say, advisedly, that the gardener who does what is possible ought not to be blamed if he cannot accomplish the impossible. That our beds and borders have continued fair up to the present time we attribute to the surface-stirring having prevented cracks and extra evaporation: to giving the little water that could be spared exactly on the principles detailed in a late article on watering, and, perhaps more especially, not to any richness in the soil, but to deep stirring and pulverisation before planting.—R. F.

COVENT GARDEN MARKET.—AUGUST 13.

The supply is well kept up both from home and abroad. Pine Apples, Grapes, and Peaches, are plentiful, cheap, and good. Raspberries are now very scarce, and of Lemons there is a very short supply, consequently they have made a great advance in price. Imports from abroad continue heavy, and comprise Greengage and other Plums, Apricots, Fontainebleau Grapes, Apples, and Pears, in abundance. Morellos are the only Cherries now to be had, and Strawberries are over.

TRADE CATALOGUE RECEIVED.

Ferdinand Gloede, aux Sablons, near Moret-sur-Loing (Seine-et-Marne), France.—List of New and Beautiful Strawberries. Autumn, 1864.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and County Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

CALADIUMS (J. Poucell.)—Those you mention were imported from Para.

WIRE NETTING FOR PROTECTING FRUIT TREES (W. F.)—We have no doubt that such a contrivance as that you name will answer admirably for protecting the fruit from birds, but as for protecting the blossom from frosts we are certain they are worse than useless. The wire, as you surmise, will have to be covered with canvass or taffeta to prevent injury from spring frosts, and wasps cannot be kept away by wire netting with half-inch meshes. The fruit we think will not be improved in flavour by being grown in a wire cage, nor will the appearance be improved by the drip from the rusted iron. Used to preserve the buds in spring, and the fruit in summer, we have no doubt that they will answer admirably, in other respects we do not perceive their utility.

AMARANTHUS (Q. Q.)—We do not recognise the Amaranthus by the leaves, which only appear to be those of a small-leaved variety of the Amaranthus melancholicus ruber. As it has grown so freely, and is so bright in colour, we should certainly save seeds of it, and try it another year. As it does so well outside, we do not think it would seed any better by being taken up, potted, and placed under glass. Having one in a pot place it in a light situation in a viney, or rather warm greenhouse, and it will seed more surely than if kept in a hothouse. Our Amaranthus melancholicus ruber seeds very freely in a greenhouse. If your plant is a better grower than the Amaranthus melancholicus ruber, of which it is probably a variety, it will be a valuable addition to our list of ornamental-foliaged bedding plants. It is usual for the Amaranthus to have the foliage almost green when grown in a strong heat, and partial shade; but the colour becomes brighter when the plants are exposed to the full influence of light.

RAISING FERNS FROM SPORES (Ruby)—Provide a bell-glass—say one of 6 or 7 inches in diameter, and a pot large enough to allow the glass to go about half an inch into the inside of it. Put a large crock or piece of pot over the hole in the pot, and on this place smaller pieces so as to fill the pot to one-half its depth. A layer of moss or the rougher parts of the compost should then be placed over the drainage, after which fill the pot to the rim with a compost of turfy peat, with a little sand intermixed. Gently press it down, leaving the soil slightly elevated in the centre of the pot. Water with a rose watering-pot, and place the pot in a saucer of water, which should never be allowed to become empty afterwards. Whilst the surface of the soil is wet with the watering, brush the spores of the frond on to the soil with the hand, and when this is done put on the bell-glass. The pot should be kept in a moderately shaded and moist part of the greenhouse. The surface of the soil must be kept constantly moist, which it will be if the saucer be kept full of water, and the bell-glass constantly over the pot. If, however, it become dry, a gentle sprinkling of water should be given through a very fine rose. When the seedlings appear the bell-glass may be tilted a little on one side by placing a small stone under the edge. After the seedlings gain strength they should be gradually exposed by removing the bell-glass by degrees, and potted singly when of sufficient strength. You will only succeed in raising the harder greenhouse species in a greenhouse; for the hardy kinds, however, it will answer admirably.

VINES FOR A COOL VINEY (Idem)—For a cool house you cannot have a better Grape than the Black Hamburg. Plant two Black Hamburgs, two Victoria Hamburgs, one Royal Muscadine, and one Buckland Sweetwater. We do not perceive any insect on the Vine leaf; but we noticed those appearances usually presented by leaves infested with red spider. It is also scorched, probably by water standing on it, and for want of air early. If you notice a very small reddish-looking insect on the under side of the leaves, syringe forcibly twice daily with water, but if the Grapes are ripening, or ripe, light a gentle fire, and sprinkle a little sulphur upon the heated surface, putting it on wet. The Nasturtium is certainly very curious, the flower especially, but without seeing the plant we are not able to form a proper opinion of its merits. As a curiosity it is worth preserving, and if you have no objection you may send us a few seeds, and we will prove the plant, and let you know the result.

WILD PLANTS CULTURE (A. G.)—You will be most likely to succeed with these by providing the same conditions artificially as those in which the plants are found to thrive best naturally. Make the soil as nearly as possible like that in which the plants have been growing; and the situation, whether open, sheltered, exposed to the sun, or shaded, and other circumstances should likewise be taken into account. Most native plants will grow in moderately light loam two-thirds, and leaf mould one-third. Some require a different compost, but we cannot name them without going over the whole of the British Flora. The plants should be taken up whilst in a state of rest, or just on the point of starting into growth, and replanted in their new quarters, due regard being paid to shading and watering them until they become established. Taken as a whole, their treatment does not differ from that of hardy plants generally. An addition of rich soil or manure will assist them, but it must not be given in excess.

VARIOUS (G. H. Green)—The idea that Peas and Beans grow the "contrary way in the pod in leap year" is preposterous. We do not know when Father Gavazzi Pansy was sent out.

WHITTLESEY'S LOCOMOTIVE SEAT—We have received several inquiries where this can be purchased. Can any of our correspondents say where?

SNAKE CUCUMBER NOT SETTING FRUIT (Lex).—We think you do not admit sufficient air, and the plants grow quickly and weak. Give air at 75°, and impregnate the blossoms, and we think they will then fruit freely. The plants should have all the light practicable, and the blossoms must be kept dry whilst they are open. The temperature should not be lower than 60° at night.

POT ROSES NOT BLOOMING—COCOA-NUT FERN BASKETS (J. J. J.).—You say your Roses have not been standing out on ashes for the last six weeks. We can only say they ought to have been, and likewise plunged up to the rim in the ashes to preserve the roots from the burning sun. Pot the plants in the beginning of September, and prune them when the buds begin to swell after taking into the house. If the Epicrises were shortened in the spring after blooming, the shoots will need but little shortening now. What is done now must be confined to shortening the irregular growths. Mignolette in pots is usually poor and wiry after the first blooming is past, and the plants kept over summer in a greenhouse are the same, which we think is stated in the article to which you allude. It is not necessary to drill any holes in the cocoa-nut shells, except to hang them up by, but a hole may be made at the bottom to let water escape, yet water can pass through the husk, which is different from the shell. The husks contain the fibre so extensively employed for ropes, mats, brushes, &c.

GERANIUMS IN POTS AND PLANTED OUT (Inquirer).—Your Geranium, judging from the leaf and flower enclosed, is probably Princess of Prussia, which it much resembles. We are not, however, sure about it, for we did not observe the zone on the leaf, which is always faint; neither is it possible to name Geraniums by a flower or two and a leaf. It is necessary to see the plant to be able to speak decidedly. Geraniums have suffered much this year, like everything else, from the long drought, and yours would suffer more by being in pots. Probably the manure water has been applied in too powerful doses, which is prejudicial, and in any state not preferable to rain water for watering Geraniums in beds. Unless the ground is wet and rich we like to plant Geraniums out of the pots, but in rich soils we prefer them in pots, as their luxuriance is then, to a great extent, restrained, and they flower more profusely. In light soils, however, they are better planted out. If anything, the plants take up best when plunged in pots, and are kept over the winter with greater certainty than when planted out and taken up and potted. There is, however, no danger to be apprehended by either plan.

VINES OLD AND NEGLECTED (H. F., Bristol).—A work will shortly be published at our office, which we think will suit you, and if you are in need of further assistance we shall be glad to afford it. Without a personal inspection, or full particulars of the condition of the Vines, we are unable to advise you at present. Flowers of sulphur and flour of sulphur are the same.

CARROT GRUBS (Bristol).—The larvae which have devoured the young Carrots are the surface grubs of caterpillars of the Heart and Dart Moth *Agrotis segestum*. They are this year extremely abundant, and very injurious. Hand-picking, in the manner described above, is the best remedy.

RAISING WATER (Short of Water).—If the difference of level between the river and the bottom of the piston of an ordinary pump, notwithstanding the distance of the latter from the river, be no more than 23 feet, we should think that water would be raised. Theoretically the pressure of the atmosphere is equal to supporting a column of water 33 feet in height, but practically it is found that ordinary pumps do not work well when the water has to be raised more than 25 feet on account of its friction in the pipes, and a perfect vacuum not being secured. With such a length of pipe as would be necessary in your case the friction would be great, and the pump, consequently, if it did act would be hard to work. If you could not use a force pump you might construct a cistern into which the water might be pumped with ease from the river, and thence by another pump into the garden.

LA CONSTANTE STRAWBERRY.—In answer to "Hugh Bowditch," and several other inquirers, we can only refer them to our advertising columns. We cannot deviate from our rule of not recommending one nurseryman in preference to another.

MILDEW ON CUCUMBERS (Bert).—The white spots on the leaf of your Cucumbers are, no doubt, mildew, which often, nay almost always, appears in the autumn. If the plants are otherwise healthy, a partial thinning of the vines and covering the ground with fine fresh leafy or turfy mould, and then giving a good watering with liquid manure, will, in general, encourage a fresh growth, and the rapid progress of the disease will be arrested; but it is next to an impossibility to ward it off long, for sooner or later in autumn it will make its appearance and the plant will succumb to it.

CROPPING GROUND AFTER POTATOES (Bert).—You may still plant some Broccoli in addition to the Greens that you say are in, or you may sow a good width with Turnips. Spinach also may be sown as late as the 1st of September if that vegetable be thought likely to be wanted, while a portion of the ground, or some other piece, ought to be prepared for early Cabbages, and a bed of autumn Onions ought to be sown in the third week of August; in fact there are so many ways of occupying ground that we can hardly point out any one in particular better than the rest. If you expect to meet with a market for the produce, and the situation is a sheltered one, a large breadth might be planted with Parsley from seedlings plants raised in April, or anything else likely to insure a good return. We would not advise any crop, especially for pig-feeding, rather let those animal come in for their share after their superiors have been served. Some notes on pig-keeping will probably appear in our pages shortly.

MARKET GARDENING IN NORFOLK (L. R.).—We fear we cannot give you much encouragement to start with so small a capital as you possess, especially as your experience is not very great; but if you could obtain work for a time in one of the market gardens around London, you would there see the mode by which the best vegetables in the world are grown, and, we need hardly add, profitably too. We think you had better visit some of those neighbourhoods where really good market gardening is practised, and obtain work at one, if even at nominal wages, so as to obtain experience. Most likely it will be necessary to modify this in practice in another locality, still the information so gained is invaluable, and cannot well be obtained by other means. Should you, however, prefer trying without such experience, we would advise you not to attempt to grow too much variety, but rather to aim at producing something (whatever it may be) well, so as to gain a reputation for it, and, thereby, a position, and it will be easy to regulate your operations afterwards.

RASPBERRIES (X. Y. Z.).—We think your soil must be too dry for this fruit, which requires a rather moist cool soil; but by deep trenching and removing some of the gravelly subsoil, and replacing it with soil of a stiffer nature, you have done the best you can to improve it, and a good watering once or twice will be of service during the summer. The fruit you sent was small, and would appear to have suffered from dryness. We should think the variety is the Red Antwerp, but it is difficult to say without seeing it growing.

WATER MELON CULTURE (A. H.).—They require about the same treatment as is usually given to Melons, both as regards heat and watering. The fruit itself will tell you when it is ripe.

HARDY BEDDING PLANTS (W. J. A.).—All the plants named in No. 175 are in cultivation, and may be had through any of the large nurseries. The best time to obtain a stock is now or in the spring. Cuttings of Rhododendrons may be inserted in turf sandy peat, with one-sixth of silver sand added.

DIGGING ROUND NEWLY-PLANTED PINUSES (J. R.).—This is only necessary when it is desired to move them a year or two after the date of the operation. This insures their removal with a ball, and with greater safety. Unless you contemplate removing them a year hence, it is well to let them alone; for, by doing as suggested to you, you will check growth for a year or two, and that without serving any good purpose. The idea of planting cut-down Pelargoniums in flower-beds is preposterous. They should be cut down, certainly, but not plunged, nor otherwise placed, in flower-beds. Such matters are best left to your gardener, who, it seems, is much ahead of the engineer in garden matters.

MUSHROOM-BED OUT OF DOORS (Devonshire).—It should be protected from wet completely, or nearly so, though a gentle shower would not injure the bed after the spawn has run through it. It is necessary, however, to keep it dry whilst the spawn is running, and protected from cold and heavy rains afterwards, for such destroy the spawn and young Mushrooms. For general usefulness there is no better Strawberry than Keens' Seedling, and it will do moderately well on the aspect named. We think "Henefrey's Rudiments of Botany" would suit you.

PROPAGATING MANETTE ROSE FOR STOCKS (An. Amatur).—Cuttings of this root freely, if inserted in good soil in the open borders towards the end of October or beginning of November. Cuttings of 6 inches in length will root in this way most freely, taking out the eyes on that part of the cutting which is inserted in the soil—that is, for about two-thirds of the length.

GRAPES NOT COLOURING (A Subscriber).—We think the main cause of the Grapes not colouring is their carrying too heavy a crop. Twenty bunches are sufficient for a healthy Vine to carry on an ordinary length of rafter. We are also persuaded that bedding plants on Vine-borders, in anything like numbers, are out of place, and do more harm to the Vines than the pleasure derived from them warrants. When there is a heavy crop, Grapes are longer in colouring. To prove this to you, we may instance that we have a house in which the Grapes are just now ripe. Most of them began colouring on the 1st of July; and the Vines have borne, on an average, twenty-one bunches each, except two, which have respectively forty-four and twenty-eight upon them. Now, on the Vines bearing twenty-one bunches the berries were as black as jet in eighteen days (July 19th); and in the case of that with twenty-eight bunches, in twenty-four days; and in the case of that with forty-four they are scarcely black now, but sufficiently so to enable us to know that they will be very fine after all, as some of the bunches will weigh over 3 lbs. They are all Black Hamburg. We leave you to draw your own conclusions.

BOILER SETTING (C. E.).—We do not comprehend what is meant by a division in the middle of a saddle-boiler, enabling you to have fire only over half the length of the boiler, unless it be that the first half is arched over the fire, and the other fixed, or the saddle broken by a bar at the bottom, as you represent it, which will leave a flue through one-half of the boiler, by which the smoke must pass to the other end. If once the smoke ascends it is not practicable to bring it lower than it rises in the first instance. You cannot, therefore, cause it to pass along a flue on both sides of the boiler below the level of the top of the furnace, though you may do so if not below that level, and thence take it over the boiler to the chimney. Your boiler, if properly set, which any one accustomed to such work will easily do, and if the most is made of its heating powers, will heat 800 to 1000 feet of four-inch piping.

WIRE STAND FOR WINDOW (E. D.).—You will have room for three rows of six-inch pots if it be 2 feet wide, which, we presume, it is; but if not more than 1 foot, two rows of $\frac{1}{2}$ inches will be ample. A zinc pan, to fit into the bottom of the stand, would be preferable to a number of potsaucers. You may secure the pots by packing them tightly with moss, which will protect the pots from drying winds, which are so injurious to the roots of the plants. They may further be secured by fastening them with small wires across the stand, and crossed the other way. No equinoctial gales can then move them. We are glad to hear that you have succeeded so well with Grapes in glass frames; and we think, with you, that they would be better 18 inches wide, the shape being immaterial whether it be square or triangular. The small snails must be enclosed when the tiffany bags are put on, either as eggs or otherwise, or they could not possibly pass through afterwards. Oiled paper bags are a novelty, and no doubt would answer perfectly, as they will admit a certain amount of light; and air might be admitted to the Grapes by piercing holes in the paper with a pin. If not well dried before put on they would communicate an unpleasant flavour to the Grapes. The *Daphne odora rubra* has done well, and may have been killed by the Jasmine roots robbing it of support, and the drip of its foliage. *Ceanothus rigidus* should be pruned when it has done blooming, and may then be cut in close. The young shoots should be trained in without stopping.

PRESERVING ARTICHOKE—REMOVING ASPARAGUS (D. M. Gregor).—Artichokes may be preserved for a considerable time if cut with 6 or 8 inches of stalk attached, and this be stuck in damp sand in the root-cellars. Every three or four days a piece should be cut off the end of the stalk. If you take up old roots of Asparagus they are next to worthless after replanting. We would make new beds in autumn, and plant them with plants two or three years old in the end of March or beginning of April.

BLACK TRIPOLI GRAPE (A Constant Reader).—It is the same as Frankenthal.

HARDY HEATHS (An Old Subscriber).—We presume the sand and coals are merely intended as plunging materials.

HEATING A VINEY (D. P. B.).—If we understand you aright, your house, 90 feet long, is not built on the level, but on the slope, of the ground, and that the difference in direct level, from the one end to the other, is 8 feet. If so you must place your boiler at the lowest end, and allow your pipes to rise to the other end just as your ground slopes. You need no particular boiler. You will need an open cistern higher than the pipes, at the farther end, or else an open air-pipe there. Fill the boiler and pipes, and light your fire, and you will find that the rise of the pipes will cause the circulation to be more rapid. For keeping out frost two four-inch pipes would do. For early forcing you would need three or four pipes. Of these we would only have one return, and the other flows; and they may all be on the same level, except where they issue from and join the boiler, the flow proceeding from the top, and the return going to the bottom of the boiler.

VEGETABLES RUNNING TO SEED (A Subscriber).—If you read "Doings of the Last Week," you will most likely find out the reason—namely, hot weather and deficiency of water. Many times such plants are starved in the seed-beds, and are likely to bolt, after planting, even though you can give them water. When plants cannot grow freely, so as to make leaves and leaf-buds, in self defence they resolve to perpetuate their kind by throwing up flower-stems and buds.

KITCHEN AND FLOWER GARDENING (A Constant Reader).—Reading, without practice, will never make you a gardener. You should place yourself under the tuition of some competent person before you venture to manage an establishment for yourself.

ORCHARD-HOUSE PEACHES FAILING—EVERGREEN CLIMBERS (W. L.).—Perhaps the wood of the Peach trees was imperfectly ripened. Are you sure the roots were not too dry when the tops were in bloom? The heat from the sun will do good in autumn. The various Iives would look well against such a wall, and so would the Magnolias, if you are warm enough, and would wait for them to grow.

BOOKS (A Clifton Subscriber).—A new edition of the "Fruit Manual" will appear ere long, but we cannot yet say when. (E. H.)—The "Cottage Gardeners' Dictionary" gives directions for the management of stove and greenhouse plants. For full instructions on the management of particular species, consult the pages of this Journal and the "Florist and Pomologist." There is no special work on the subject which is up to the times.

NAMES OF FRUIT (J. F. N.).—Your Gooseberries were too much bruised for determination, but they appeared to be Crown Bob.

NAMES OF PLANTS.—Although happy to oblige our correspondents whenever possible, they often send such miserable scraps as to render the determination of the species very difficult, if not impossible. (S. A. P.)—No. 5, Zebrina pendula, named last week, is better known as *Cyanotis vittata*. (*P. Selby, Birmingham*).—A Portulacaceous plant, but it is impossible to determine its name without a proper specimen in flower. (W. L.)—*Stuartia pentagyna*; *Cladodriss tinctoria* is a native of Kentucky and Tennessee. (*Chemicus*).—Both *Todea pellucida* and *Lomaria falcatula* are exotic Ferns, the former being from New Zealand and the latter from Tasmania. As far as we can judge from the immature frond sent, the latter is correctly named. (*Nos à Dolez*).—The Aloe, we presume, is *A. americana* var. *variegata*, but it is hard to say from the tip of a leaf alone.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

JOTTINGS.

(Continued from page 118.)

AFTER the steady and anxious have left the town, the streets and show-yard are occupied by a different class. Shops are closed, and the young men swell the numbers of spectators; the country people after a certain time are admitted gratis, and then begins the hurry of the show-yard. It is half-past four, and it closes at six. The band of the 200th is flagged, or, as a matter-of-fact countryman said, "tired of too-too-rooing." The real middle-class agricultural element has disappeared, and Sponge's Lóvior, the country-town swell, has taken the place—no improvement. The hearty quarrels of the herdsmen, many under the influence of John Barleycorn, come quite refreshing on the ear. They do not go the length of the two-year-olds and three-year-olds in Ireland, but they are very pretty little feuds as they stand. "Giles woant tell all as he cood about that whoite bull as has fast, but he cood an he wood;" and Tummas answers, "Speak up, and speak out mun; ye've been telling all you knows for years, and you's thinner, and yer children wuss fed." Then Giles whispers to two or three, and they all inspect the white bull, and many shake their heads; and then one points to a particular mark, and Tummas sees it, and says, "I knows he's bad there, and he looks older, but he yaint." Then there's a sort of murmuring, and one of the young men from the town comes up with friends, or, as "Immortal Will" has it, "accompanied;" and after knowingly handling the bull (we got sadly kicked at that exercise once), he says, with a grave air, and all the *diplom* of an authority, "A first-prize bull should, like Caesar's wife, be above suspicion." "Gie us your hand," says Giles, but our townsman is wise, and had "skedaddled" as soon as he delivered himself of the oracle. "What didn't say?" says Tummas, who was not deaf, but what they call "hard of hearing," which means he would not know he was in danger from a goods train till he felt it. "What didn't

say, and whose wife was he talking about?" "Yours," said a bystander. "He makes a mistake," says Tummas, "for I never was married."

It is wonderful how towards the close of the day the eloquence of the men in charge increases, and what faults they find with the winners. The contest runs between the youth of the town and the matured wisdom of the country. "Brahmas beat everything in the way of fowls," says a poultryman. "Do they lay twice a-day?" says a townsman. "Always," is the answer, "except Sundays and holidays." Townsman evaporates.

Then the time comes for removing the stock. Little knots form round the prize animals, and many a hardly-earned sixpence is spent to decorate the prize bull or horse with ribbons, that his success may be apparent to all. "I hope," says a beaten man, "you have made your great coarse animal fine enough, with all your bows and rosettes. I never did like him, and I don't." "Never mind, don't be jealous; go and borrow a hat-band, and put round yours."

Without any disorder, or ill feeling, the scene is entirely changed from what it was a few hours before. The masters are gone, the Committee men are at the dinner. The ladies went with the band. Here and there animals are seen moving across the ground. Carts are admitted to fetch poultry and sheep. Implements are being packed preparatory to removal. The task of keeping order devolves on the policemen, who do it well, and give notice to clear the ground.

The crowds are now scattered over the town—harvest for the inns and public-houses. The countrymen are growing more demonstrative, and such groups as many of those in Wilkie's imitable "Village Festival" are to be seen everywhere. It is, however, inoffensive, and remains strictly agricultural. The merits of crops, animals, and ploughing, form all the conversation. Dancing-booths, rifle-galleries, photographic studios, fortunetellers, present their charms to the lads and younger men, and the recruiting sergeant plies a good trade. When we were young there were such things as ballads. We recollect that close to Harewood Gates, in Oxford, a man used to decorate the whole of the dead wall with rows of ballads, pinned on strings. In London such things have passed away, to make room for the "Darkie's Album," "The Songster's Companion," &c.; but in the country there is still a sale, and a man and woman singing an old song to an old tune find a ring of listeners, and flocks of customers. From the public-houses, choruses, wherein the "Bold Drag-goony," and "Delight of a Shiny Night" play a principal part, are heard. The men leading home the prize animals are treated wherever they go, till at last they are obliged to admit "they never knew that horse go so crooked afore; why he went right across the street, and stumbled ever so many times!"

Peace gradually creeps over the little town, and save that now and then some "wildish fellows" gallop down the streets, and a distant noisy chorus is heard, nothing would remain to remind one of a busy day.

The improvised avenue looks sadly the next morning; the flags seem out of place without crowds. It is with the town as with a moderate family after the annual "party" it is putting-away day.

THE AGRICULTURAL HALL POULTRY SHOW AND THE POULTRY CLUB.

I SEE in your Journal of last week that Mr. Tudman invites your correspondents to "communicate directly," and they shall have all the information he can give.

In the middle of last month I wrote to Mr. Tudman asking him for the rules and regulations of the Poultry Club, with the view of becoming a member, adding some questions so like the suggestions put out by "EGOMET" that they would appear to come from the same person.

The answer I received was to the effect that the rules and regulations of the Poultry Club are available to members only—that the Club finds judges only for poultry shows, and that "they are not in any way responsible for the prize list, nor do they get up shows."

If the Poultry Club are not answerable for the prize list, nor do they get up shows, how is it that the prize list of

the forthcoming poultry show, at the Agricultural Hall, is headed with the words "Under the patronage and management of the Poultry Club?"

If the Poultry Club did not take upon itself to find judges for shows, and had not been advertised as taking the management of one, but was simply an association of gentlemen for purposes of their own, my application to Mr. Tudman might have been construed into an act of impertinence. Under the circumstances above mentioned I had a right, in common with every other exhibitor of poultry, to inquire what were the rules and regulations of the Club.

If this be the kind of information to be furnished, I suppose your correspondents, who are invited by Mr. Tudman to communicate immediately, will be as well satisfied as I am.

A public statement of the rules and regulations, with the objects proposed to be accomplished by the Club, would save your correspondents and Mr. Tudman much trouble.

It may be that this Poultry Club is a very desirable and useful body, but it certainly does not go the right way to win the confidence of the public.—GEORGE MANNING.

NEWMILLERDAM POULTRY SHOW.

THIS was held on the 2nd inst., when the following prizes were awarded:—

GAME (Red).—First, G. Hellewell, Sheffield. Second, J. Charlton, Bradford.

GAME (Duckwing).—First, J. Charlton, Bradford. Second, G. Hellewell, Sheffield.

GAME CHICKENS.—First, J. Crosland, Wakefield. Second, G. Hellewell, Sheffield.

COCHIN-CHINAS (Buff).—First, S. Pickard, Wakefield. Second, W. Dawson, Hepton.

COCHIN-CHINA (Cuckoo).—First, W. Dawson, Hepton. Second, S. Pickard, Wakefield.

COCHIN-CHINA CHICKENS.—First, W. Cannan, Bradford. Second, J. Crosland, Wakefield.

DORKING (Grey).—First and Second, S. Pickard, Wakefield. **Chickens.**—First, J. Hirst, Boy Hill. Second, S. Pickard, Wakefield.

SPANISH.—Prize, W. Cannan, Bradford. (Only one entry.)

PHEASANTS (Golden).—First, J. Ellis, Leeds. Second, H. Hinsworth, Lupset. **Chickens.**—First, W. Cannan, Bradford. Second, J. Ellis, Leeds.

PHASANTS (Silver).—Prize, W. Cannan, Bradford. (Only one entry.) **Chickens.**—First, J. Ellis, Leeds. Second, W. Cannan, Bradford.

ANY DISTINCT BREED.—First, W. Cauffman, Bradford. Second, S. Scholfield, Heckmondwike.

BANTAMS (Black or White).—First, W. Cannan, Bradford. Second, J. Charlton, Bradford.

BANTAMS (Any variety).—First, S. Scholfield, Heckmondwike. Second, J. Wade, Leeds.

TURKEYS.—First and Second, J. Fawcett, Wakefield.

GEES.—First and Second, J. Fawcett, Wakefield.

DUCKS (Rouen).—First, J. Hirst, Boy Hill. Second, R. Atha, Boy Hill.

BANTAMS (Game).—Prize, G. Hellewell, Sheffield. (Only one entry.)

YORKSHIRE AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE above Show, which is one of the migratory class, was held at Howden on the 3rd, 4th, and 5th inst. The poultry entries were not so numerous as at some of this Society's previous Exhibitions, but many pens of superior excellence were shown.

In the class for old *Spanish*, Mr. Rodbard was first; but the commended pen of Mr. Beldon would have been a formidable competitor for the first prize if the cock had not been diseased in his feet. Mr. Rodbard was also the exhibitor of a good pen of dark *Cochins*. In the adult *Game* classes, Mr. Beldon and Mr. Julian exhibited some very good birds, and the competition between them was very close. The *Game Chickens* were not so good as might have been anticipated at a Yorkshire Show. Mr. Beldon obtained the chief share of the *Hamburg* prizes; and in the *Poland* classes he was without a competitor.

The following is a list of the awards:—

SPANISH.—First, J. R. Rodbard, Bristol. Second, S. Robson, Brotherton. Highly Commended, H. Beldon. **Chickens.**—Prize, S. Robson.

DORKING.—First, F. Key, Beverley. Second, M. Hunter, Green Hammerton. **Chickens.**—Prize, Rev. J. F. Newton, Kirby-in-Cleveland.

COCHIN-CHINA (Black or White).—First and Second, W. Dawson, Mirfield. **COCHIN-CHINA (Any Colour not Black or White).**—First, J. R. Rodbard, Bristol. Second, H. Beldon, Bingley. **Chickens.**—Prize, S. Robson. Highly Commended, H. Beldon.

GAME.—First, H. M. Julian, Hull. Second, H. Beldon. Highly Commended, J. N. Holmes. **Chickens.**—Prize, H. Beldon. Commended, J. Thornton.

HAMBURGS (Golden-spangled).—First, H. Beldon. Second, C. Cowburn, Leeds. **Chickens.**—Prize, C. Cowburn.

HAMBURG (Golden-pencilled).—First, H. Beldon. Second, S. Smith, Halifax. Highly Commended, H. Pickles. **Chickens.**—Prize, H. Beldon. Highly Commended, H. Pickles.

HAMBURG (Silver-spangled).—First, H. Beldon. Second, E. Ardington, Howden. **Chickens.**—Prize, H. Beldon. Highly Commended, C. Cowburn.

HAMBURG (Silver-pencilled).—First, H. Beldon, jun., Skipton. Second, H. Beldon. **Chickens.**—Prize, H. Beldon. Highly Commended, H. Beldon.

POLAND.—First and Second, H. Beldon. **Chickens.**—Prize, H. Beldon.

ANY OTHER DISTINCT BREED NOT PREVIOUSLY CLASSED.—Prize, H. Lacy, Hebedon Bridge. Highly Commended, F. Powell; H. Beldon. **Chickens.**—Prize, H. Lacy.

BANTAMS.—Prize, H. Beldon.

SINGLE COCKS.—**Spanish.**—Prize, H. Beldon. **Dorking.**—Prize, H. Beldon.

Cochin-China.—Prize, J. Bell, Thirsk. **Game.**—Prize, H. Beldon. Highly Commended, H. M. Julian. Commended, J. Rennison. **Hamburg (Golden-spangled).**—Prize, H. Beldon. **Hamburg (Golden-pencilled).**—Prize, S. Smith. Highly Commended, H. Pickles. **Hamburg (Silver-spangled).**—Prize, H. Beldon. **Hamburg (Silver-pencilled).**—Prize, H. Beldon.

GEES.—First, R. Johnson, North Cave. Second, S. Walker, Howden.

DUCKS (Rouen, or any other Breed not Aylesbury).—Prize, W. Bradley, Wellington.

The Judges were Mr. J. H. Smith, Skelton Grange, near York; Mr. Jolly, Acomb.

PIGEONS AT NEWCASTLE-UPON-TYNE AND DARLINGTON SHOWS.

At the Exhibition of the Northern Counties Agricultural Society at Darlington Mr. J. W. Botcherby, of Darlington, acted as Judge, as he did also at the recent Show of the same Society at Newcastle-on-Tyne. The re-appearance of Mr. Botcherby as a Pigeon Judge renders it necessary that something should be done to prevent a recurrence of such decisions as those named by Mr. Yardley at page 97, and alluded to in your own note relative to the many strange details you have heard "about the Pigeons at Newcastle-upon-Tyne."

To my having exhibited Pigeons at the last Darlington Show, and Mr. Botcherby having repeatedly declared at the time in answer to universal expressions of dissatisfaction that "he would never judge again," may be attributed the fact of the decisions having escaped criticism so far as I am concerned. Now, however, that Mr. Botcherby has once more ventured to undertake a post for which he is altogether unfitted, further silence would be an injustice, more particularly as it is well known that the appointment of Mr. Botcherby at Darlington was most strenuously opposed by one of the Committee, a gentleman well able to give an opinion; and that he was met by the declaration of the Honorary Secretary when the Judges were appointed that he had engaged Mr. Botcherby and would not have any one else! "A COMPILER OF THE DARLINGTON SCHEDULE," who has ably exerted himself in the poultry department, and to whom its consequent improvement is justly due, will no doubt correct me if such be not the case.

A few remarks will enable your readers to form their own opinions of the awards at Darlington. In the first place, a local exhibitor penned the birds, and his "partner in the fancy" accompanied the Judge, the only pen exhibited by this person taking the first prize, though, with the exception of a half-crown prize at Middlesborough, it never figured as a prize pen at any other place. In Carriers some of the best birds were unnoticed. The silver cup for the best pen in the Show was awarded to an old Dun cock, a draft from the loft of one of our well-known exhibitors; while one of the best Carriers in the kingdom and in her prime, a black hen belonging to Mr. Else of London, was shown. In Powters, a hen second at Birmingham a few days previously was not considered worthy of commendation, and £5 was refused for another unnoticed bird in the same class. At Glasgow, a few days subsequently, two pens entirely passed over at Darlington took first position in, perhaps, the strongest competition known. The other classes were no exception. In one two cocks were first against a very superior pair, and so on; but if further particulars are required they can be forthcoming.

One of the Honorary Secretaries of the Newcastle Show, Mr. Shorthose, was at Darlington, and could scarcely be ignorant of the extreme dissatisfaction then so loudly expressed; and it is unaccountable how that gentleman could have been induced to sanction such an appointment for Newcastle. At the latter place, in Powter cocks a bare-skinned bird took first; in Barbs the best cock stood second, while the best hen was passed over altogether; in Jacobins

the best were not mentioned, while the worst in the class—a pair of coarse Yellows, the cock nearly without hood, took first. In Owls perhaps the most unusual decisions were given. Coarse rubbishy Blues won; while good Whites, and a most exquisite pair of Black-tailed Whites, extraordinary in head and beak, were unnoticed. In the medal class for Owls, a pair of Squeakers with their nest feathers on won against a splendid pair of Foreign Blues. In Any other variety white Dragons took first; but it seems from Mr. Yardley's letter that on his bringing to light his pair of Satinettes this had been reversed. As a climax, Mr. Hewitt, observing that an exhibitor had taken first and second in one class, induced the Secretary to reverse the cards "to save appearances."

Comment is unnecessary. Facts incontrovertible are given; and exhibitors must take means to prevent a repetition of such escapades as have brought an unenviable notoriety on the two northern shows.—A FANCER.

[Our rule is not to criticise the awards of competent Judges; but where a Judge by repeated wrong decisions demonstrates that he is not qualified for the office he has accepted, we feel that it is our duty to denounce the error, especially when a Committee persists in retaining his services. Such a case is that now before us; and having the testimony of three well qualified critics, all concurring in denouncing Mr. Botcherby's awards, we have no hesitation in inserting this letter from one of them; and we hope for his own sake, for the sake of the Society, and for the sake of exhibitors, he will henceforth decline acting as a Judge of Pigeons.]

I was glad to see a complaint from Mr. Yardley of the judging, or rather misjudging, of the Pigeons at Newcastle-upon-Tyne Poultry and Pigeon Show. I can bear testimony to the truth of Mr. Yardley's statement.—HONESTY.

"A DEVONSHIRE BEE-KEEPER" VERSUS THE "TIMES" BEE-MASTER.

SUBJOINED are two letters which our esteemed correspondent, Mr. Woodbury, has addressed to the *Times* in reference to the articles which have appeared in its columns from the pen of "A BEE-MASTER." We publish them without comment, for the subject could not be in better hands.

"TO THE EDITOR OF THE 'TIMES.'

"SIR,—As an English bee-keeper of many years' experience, I have been grieved at perusing the letters on the subject which have recently appeared in your columns, and which I cannot but think are likely to give our continental neighbours and transatlantic brethren a very mean idea of the skill and knowledge of British apiarians. Every one has a right to expect that when a subject is mooted in the *Times* the writers who step forward to discuss it will be at least up to the age in which they live; and it is because I perceived the gentlemen whose letters have already appeared are writing in the spirit of a bygone time that I venture to point out a few of their mistakes.

"First, with regard to bee communities remaining at peace with each other. This they will do so long as both are strong and tolerably prosperous, and honey continues plentiful out of doors; but as soon as honey-gathering is over, innumerable spies from strong colonies try the mettle of their neighbours, and should any one or more betray signs of weakness, the war of Germany against Denmark is enacted on a small scale, with this difference, that the invaders take absolutely all, and utterly destroy the vanquished; unless, indeed, the latter, as sometimes happens, join the confederation, and assist in the plunder of their own stores. Whatever virtues bees possess, therefore, honesty, or even the slightest respect for *meum et tuum*, is certainly not among them; nor have they any other guide in this particular than

"That good old rule, the simple plan,
That those should take who have the power,
And those should keep who can."

"But, while pleading guilty to the sin of dishonesty among my little favourites, I must absolutely acquit them

of the charge of drunkenness, or a 'passionate liking for rum and strong ale.' Neither the one nor the other will bees meddle with, unless their natural repugnance to such abominations be overcome by their liberal admixture with either honey or sugar in some form; nor will they even in this case accept the proffered libation so readily as if pure water were used to dilute it.

"Mr. Harbison, a sturdy citizen of the American Republic, considers the queen a simple machine for laying eggs, absolutely under the workers' control, who stimulate or repress her fecundity according to circumstances. I do not go these lengths, but I know Mr. Harbison to be far nearer the truth than your correspondent who talks about the queen's 'giving orders,' and says that 'if you interfere with her the watcher bees will sound the alarm, and a thousand stings, like swords, will be unsheathed.' I am in the constant habit during the season of handling queen bees, and I can assure him that nothing of the kind ever takes place. The note of distress from a captive queen passes totally unheeded by her subjects; and though a few stray workers may alight on the bare hand that holds her prisoner, and even lick her as she is held between the fingers, the sight of her captivity has no effect in moving them either to anger or resentment. When she is indeed gone for ever they generally fall into confusion for a time, and appear to seek her, but even this is not invariable. I have, moreover, another fact to communicate, which will probably startle many of your readers. Regicide in its worst form is not unfrequently perpetrated by bees. The deaths of Charles I., or Louis XVI., or even that of Marie Antoinette, were indeed merciful when compared with that inflicted by these little termagants on their own mothers. Hurled in one instant from the height of popularity to the depth of misery, the poor deposed sovereign finds herself pinioned and unable to move a limb, among a dense mass of her unnatural children; and there she remains, without the possibility of escape, until death, very many hours afterwards, puts an end to her misery. Often have I seen the poor dried and shrivelled carcass, betraying in the distorted rigidity of every limb the severity of its last agony; and all this, so far as we can discover, without a cause! The youngest and most fertile queens are sometimes victims, and that even at a time when their loss entails extinction on the community. Nay! listen young and newly-married brides, I have known queens devoted to this horrible and lingering death immediately on their return from their wedding excursion, and before they had experienced the joys of maternity.

"Stewarton (Ayrshire) hives are octagonal, not hexagonal, in form, nor is there the slightest reason for imagining that the bee, which builds an hexagonal cell, would prefer a hive of the same shape. So far from a cottager being able easily to make the four compartments comprised in a Stewarton-hive, it would puzzle many a skilled carpenter to dovetail even a single octagonal box accurately together.

"Common sugar (lump sugar is best), does not require to be exposed to a heat of 300° to be available by bees. Three pounds of lump sugar mixed with two pounds of pure soft water, and boiled a minute or two, forms excellent bee food.

"Pressure by a watch-key and tobacco, as remedies for a bee sting, are no new discoveries. I advise any one stung by a bee to take the sting out as soon and as carefully as possible, leaving no part of it behind, and then let the wound alone. All the so-called remedies which I have tried (and their name is legion), only irritate and increase the swelling, which otherwise would soon disappear.

"If any one has a swarm consisting only of 5000 or 6000 bees let him not take the trouble of hiving it. A good swarm will weigh 4 lbs., and I have known one weigh 8 lbs. Now 5000 bees are computed to go to a pound, and this is not too many, for a friend of mine counted and weighed 5020 freshly-killed bees this spring, and they only weighed 12½ ozs. Let any one, therefore, do a simple sum in mental arithmetic and say if 15,000 to 30,000 are not within the mark, even allowing for the weight of honey carried off by the swarm.

"Brood in supers is not always drone-brood, nor is the heat of drones necessary for the maturation of brood. If it were, they would not be absent in spring, when the weather is coldest, and a great quantity of brood is hatched, nor would they be destroyed in autumn, when the temperature

is falling. There is, of course, a well-known and sufficient reason for the multitude of male bees in summer, and that is that queens may run no unnecessary risk by unavailing matrimonial excursions, as their loss at that time would entail destruction on the entire community. Neither does the queen exercise 'queenly prerogative and dignity' by selecting her husband. She launches into the air unattended, and there mates sometimes with a drone from a hive a mile or two distant from her own.

"Bees are never nursed by other bees. They are strict utilitarians, and totally devoid of sympathy. 'Those who cannot work shall not eat' is a law applied with stern impartiality alike to the disabled worker and useless drone. He, therefore, who would teach or learn a lesson in charity must look elsewhere."

"With regard to the hive described and recommended in the *Times* of the 4th inst., it is simply one on the 'nadir,' or 'nether' principle, a principle which has often been tried, and as often found wanting; and for this reason it is opposed to the instinct of the animal itself—an instinct which prompts it to place its honey above and its brood below. It may, therefore, be safely asserted that any stock of bees which is compelled to place honey in a 'nadir' would collect double or quadruple the quantity in a 'super.'

"I feel I owe an apology to those gentlemen upon whose letters I have commented thus freely. Their motives are so unquestionably good that their errors would have passed unnoticed by me had they sought publicity through any other channel. As it is, I am very desirous of making it known to our continental and American friends that their letters do not convey an adequate idea of the amount of knowledge of the subject possessed by British bee-masters. Not only have we frame-hives second to none ever made for ingenuity and convenience, as well as the necessary skill to avail ourselves of the advantages they afford, but we are no strangers to the superiority of the Italian race of honey bee (*Apis Ligustica*), and are even now ransacking the world in the search after other species, while we have repeated and verified the experiments and investigations of Von Siebold, which establish, beyond question, the truth of Dzierzon's great discovery of parthenogenesis in the honey bee.—T. W. WOODBURY, Mount Radford, Exeter, Aug. 6."

"TO THE EDITOR OF THE 'TIMES.'

"SIR.—Although we are informed on the authority of 'A BEE-MASTER,' that 'bees have not learnt to read the *Times*', we must not be surprised if it should be announced by him in a future letter that his bees have added this essential accomplishment to their innumerable moral virtues. Pending their acquirements of this faculty however, and the consequent irritation which is to bring me to my senses (or to drive me out of them), permit me to suggest, that in these days of railways and excursion trains, a trip into Devonshire would entail little fatigue or expense on their champion. I should myself be delighted to see him, and should have little difficulty in proving to his satisfaction the truth of every statement made in my letter of the 6th inst. I am now writing in a room overlooking a garden containing a score of inhabited hives with the queens of each of which I am on visiting terms. As your correspondent among other compliments is pleased to accuse me of 'crass ignorance,' I shall be happy to take him into this garden, and, after describing the peculiarities and personal appearance of the queen of each hive, to introduce him to every one in succession, and thus give him the opportunity of testing for himself the correctness of my description. Can 'A BEE-MASTER' do as much with his bees?

"It seems, also, that I am an 'irritable old apriarian,' whilst 'A BEE-MASTER' is 'really not irritated.' Of the amount of 'irritation' displayed on either side I leave your readers to judge, and am happy to say that your correspondent, who I am informed has a son as old as I am, is somewhat at fault with regard to my age, though what this has to do with the question passes my ability to discover.

"My bees are always well provided with food; but even his guess of poverty is as wide of the mark as the other. Avarice is as common among bees as among 'old gentlemen,' and the best provided stocks are often the most predatory.

"When 'A BEE-MASTER' pays me a visit we will try the experiment with 'strong ale,' and in the meantime I will lay in such a stock of sauces and other condiments as shall render his meal, which is to consist of bees, beer, and feeding-pan as digestible and as little disagreeable as possible,

"I may remark in the interim, that the presence of beer in bee-food has long been dispensed with by the best modern apriarians.

"I do not, as I said before, go all lengths with Mr. Harbinson, nor am I a 'Red Republican,' or even an admirer of Abraham Lincoln, but I am a conservative in politics, a churchman in religion, and a loyal subject of Queen Victoria. Nevertheless, I re-assert, that regicide by bees has frequently come under my observation and is not unknown to others, although I am, I believe, the first Englishman who has recorded it in print. Those who know me are aware that I am not given to exaggeration, and in this case I repeat, that I have told merely the plain truth. Will 'A BEE-MASTER' kindly inform me in what respect he deems a conscientious search after, and a keen appreciation of the truth as regards bees incompatible with the strictest orthodoxy both in politics and religion? I fancy if he will read through his last communication calmly and dispassionately, he will come to the conclusion that the 'machine for talking [or writing] nonsense,' has been called into play on his side.

"Sugar in order to be converted into barleysugar must first be diluted with water, and in this state is available to bees. Am I not correct, therefore, in stating that subsequent exposure to a heat of 300° is unnecessary? When 'A BEE-MASTER' visits Exeter, I shall be happy to show him how to administer liquid food to bees without either smearing their wings or clogging their feet.

"But it appears I have not 'watched the habits of bees,' or studied the results of the investigations of Huber. This is another random shot, and like the preceding ones it flies under the mark. Huber (or rather his assistant, Francis Burnens), was a keen and generally an accurate observer, far in advance of the age in which he lived; but he was not invariably correct, and I have studied his investigations and the habits of bees sufficiently to know when Huber is to be relied on and wherein he was mistaken. The imputation of 'ignorance' on this point comes, moreover, with ludicrous incongruity from a man who not only fails to recognise, but absolutely derides as 'absurd' Huber's 'explanation of two thousand drones where there is only one queen, with, perhaps, a couple of princesses,' an explanation which has been deemed sufficient and satisfactory by every intelligent apriarian from his time to the present day.

"A swarm consisting only of five thousand bees has, it is said, been kept through the winter by feeding, and has done well in a magnificent honey season. May we venture to ask for particulars? How was the number of bees ascertained? Were they counted, or were they weighed? If counted, what was their exact number? If weighed, their precise weight? Were they hived in an empty or a combed hive? What did they cost in food? I need hardly say that if they cost as much in food as the purchase-money of a good swarm, they really were not worth hiving.

"With regard to the utter absence of sympathy in bees, I have nothing to modify or retract. Allowing for the influence of imagination, 'A BEE-MASTER,' doubtless, describes what he has seen pretty correctly. He has erred only, as many others have done before him, in ascribing the actions of his bees to wrong motives. Had he witnessed the *dé-nouement* he would either have found the disabled worker left to die by inches on the floor-board totally unheeded by her sisters, or bundled neck and crop out of the hive shortly afterwards.

"Permit me in conclusion to say a few words to those gentlemen who have written thanking me for exposing some of the inaccuracies of your Tunbridge Wells correspondent, whose effusions, as they very justly remark, are likely to do far more harm than good. If it were desirable I could of course more than double the list of his mistakes which I have already noticed. But enough has been done. If the *Times* 'BEE-MASTER' continues steadfast in the pursuit which he appears to have taken up so ardently, he may in time become worthy to bear the title he has somewhat prematurely assumed. Whenever that period arrives we may be very sure that he will look back upon his share in this

correspondence with mortification and regret. On this account I should be extremely sorry to adopt a course which might probably lengthen the discussion, and by so doing call a deeper blush to his cheek, and add poignancy to his regret.—T. W. WOODBURY, Mount Radford, Exeter, 11th August, 1864.

"P.S.—Since writing the above, I have received an admirable letter from your correspondent, the Rev. William Law. I should be indeed glad if 'A BEE-MASTER' would meet me in the same spirit."

BEES UNITING VOLUNTARILY WITHOUT FIGHTING.

A curious circumstance has occurred to one of my hives this year which may be worthy of recording. A very strong hive about three years old swarmed in May; in a few days it swarmed a second time in a high wind; at the same time the hive next to it on the right side swarmed likewise, and both swarms went into this hive, which I shall call No. 2. About three days after, the bees from No. 2 marched into No. 1 in great numbers without being interfered with. About a fortnight afterwards, early in the morning, I found the bees from No. 1 hive walking leisurely into No. 3, on the left hand, without being taken any notice of by those they were visiting. They walked steadily along the bench in a line about 2 or 3 inches apart. After this happened I felt the weight of No. 1 and found it was very heavy.

Yesterday I found No. 1 hive all in commotion as though young bees were coming out dancing for joy; but as this continued until the evening, I perceived something was wrong, and on lifting the hive found it to be almost empty, I, therefore, lifted the hive and after a few minutes rapping all the bees left it and crowded into No. 3. I am at a loss to account for the hive flourishing so well, and yet deserting without fighting.—H. M.

[The probability is, that the young queen of No. 1 was lost through mistaking her hive on the return from her wedding trip. When hives are close together this accident is very apt to occur. There is, also, much more intercourse between stocks so situated than we have any idea of, and the voluntary union of two colonies under such circumstances is, therefore, not much to be wondered at.]

COMMENCING BEE-KEEPING.

HAVING just read Mr. Woodbury's very interesting letter on bee-keeping in the *Times*, and also those which have recently appeared in the same journal, I feel myself greatly perplexed how to reconcile the various methods of management, seeing that each individual professes to give the result of much experience. I should tell you that I am ignorant of any method of management, and am about commencing bee-keeping next spring. Will Mr. Woodbury be so obliging as to favour me with his advice as to what books I should procure upon the subject?—W. G.

[My advice is, "Do not attempt to run until you are able to walk," or, in other words, do not depart much from the old well-understood mode of management until you have had some experience, and then advance by degrees. Get "Bee-keeping for the Many," price 4d., and begin with Payne's improved cottage-hive made rather larger than therein described, on which put small supers. These hives will throw swarms, and thus increase your stock. If they get too numerous try to drive some of the swarms, and unite to others in the manner recommended in the little manual. As you become accustomed to the management of bees you will probably wish for better and more convenient hives, such as frame-hives. To this there can then be no objection, but I never advise any one to buy costly hives until they have sufficient skill to avail themselves of the advantages they afford. Read THE JOURNAL OF HORTICULTURE, and avail yourself of editorial advice in any difficulty.—A DEVONSHIRE BEE-KEEPER.]

SUNDERLAND AND NEWCASTLE ORNITHOLOGICAL SOCIETY.—We understand that the first annual Exhibition of this Society will take place at the Athenaeum, Fawcett Street,

Sunderland, on the 1st, 2nd, and 3rd of November next. Nine silver cups, value £5 each, will be offered for competition, five of which are offered by John T. Lawrence, Esq., of Liverpool. For particulars as to the prizes offered we must refer to the published schedules, which may be obtained of the Honorary Secretaries, Messrs. G. R. Potts, Albert Forge, and J. R. Robinson, 55, Nile Street, Sunderland.

CUCKOOS.

HAVING a young Cuckoo which I am very anxious to keep alive through the winter, will any of your correspondents who have ever kept one, kindly inform me how they have fed it? I am feeding mine now on hard-boiled egg, chopped meat, caterpillars and moths when I can get them, but I am afraid when the insect season is over my bird will suffer from the loss of its natural food.

Any hints as to feeding and temperature, will greatly oblige.—A. K. C.

TO PRESERVE RHUBARB.—Strip off the peeling, cut into inch pieces, then put 1 lb. of sugar to 5 lbs. of Rhubarb, stew until soft, then strain out the juice by pressing through a cloth, spread the Rhubarb on plates, boil or simmer down the juice quite thick, turn it over that on the plates, dry it in an oven or by the stove, the same as fruit, put into a jar and pound it down hard, covering closely, and it will keep for years; and, flavouring with essence of lemon, it will make a far more delicious pie than when green—of course, more sugar must be added when used.—(*Canada Farmer*.)

OUR LETTER BOX.

APPLES AS FOOD FOR POULTRY (*P. M. K.*).—We can say nothing as to apples as food for poultry, but they will eat them readily if given now and then for a change. Given whole, they will pick them to pieces, or if chopped fine they will pick the fragments readily. They are wholesome for them.

HENS EATING EGGS (*Amateur*).—The desire to eat eggs shows that a hen or pullet is out of condition. A diseased state of the insidi will be brought about by the use of meat, greaves, and other stimulants. They have produced early eggs, but also have caused an inward craving that can be satisfied only with unnatural food. She therefore eats her eggs, and will do so till she is cured. She must be purged frequently (every other day), with castor oil, a tablespoonful at a time. Be careful not to over-feed, and avoid all stimulants. Place hard artificial eggs in her nest, or where she lays; and although you may lose her present laying, you will probably save the next.

BIRDS (*J. Newland*).—All questions relating to this subject should be addressed to the Editors.

PURCHASING BEES AND BEE-HIVES—WORKS ON BEE-KEEPING (*Marple*).—The best time to buy bees is in March, when they have stood the winter. Strong and sufficiently heavy stocks should be selected, and the judgment of a skilled bee-master obtained if possible. The price of a stock of bees, in the spring, would probably vary from 15s. to 30s. in different localities; and we are unable to recommend one place as better than another for making the purchase. Bees will not be injured by a change at any season, if the distance be not less than a mile and a half; but if moved in warm weather, and when the combs are heavy, great caution is requisite. We cannot undertake to recommend any particular hives, but may state, generally, that Payne's improved cottage-hives are well adapted for ordinary, and Woodbury frame-hives for scientific, bee-keeping. Any kind of hive can be secured against accident; and Messrs. Neighbour & Sons, 149, Regent Street, will give every information as to price. (T. W. Cowan).—Messrs. Neighbour & Sons, 149, Regent Street, and 127, Holborn, will supply you with bees. The best books on the subject are "Taylor's Bee-keepers' Manual" and "Bee-keeping for the Many" (English), and Langstroth's "Hive and Honey-bee" and Quinby's "Mysteries of Bee-keeping" (American).

EXPERIMENTING WITH A YOUNG QUEEN (*S. A., Baintree*).—We fear for the result of your experiment. It is dangerous to trifle with virgins.

CANARIES (*Chemicus*).—We do not know the address of Mr. Roper who won the first prize for Buff Belgians at the Crystal Palace Show. "Canaries and British Finches," contains representations of all the principal kinds.

RABBIT-HUTCHES.—"J. G. C." says, Can you tell me where I can buy good Rabbit-hutches constructed upon the principle recommended in the "Rabbit-Book for the Many," at a moderate price?

LONDON MARKETS.—AUGUST 15 POULTRY.

The supply is moderate, and the trade almost nil. London is "out of town."

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 72.3°, and its night temperature 49.0°. The greatest heat was 89° on the 25th, 1859; and the lowest cold, 32°, on the 29th, 1850. The greatest fall of rain was 1.82 inch.

DRY WEATHER AND WATERING.

T has often been said that a certain amount of discontent is essential to happiness; and grumblers, even those habitually so, often enough live to a good old age, carrying with them the propensity they acquired in their youth: grumbling, therefore, like medicine, may be regarded as very good in its way, and may, doubtless,

be quite as necessary. In the various avocations of life there is always something to grumble at if an object is looked for, and too many of us are apt to hunt after one. Gardeners complain in winter of its being too cold; by-and-by we find, perhaps, that the soil does not work well, and we complain then that the winter has not been cold enough; while in summer contrarieties are alike wished for and found fault with. At the present time (August), we think we are suffering extremely from want of water, while in all probability the crop of fruit we may have next year may owe its origin in a great measure to the dryness of the present period. Dry, bright, sunny weather is at most times grateful to vegetation, certainly so to that which is established some depth in the ground; and when we consider that in such is embraced a considerable portion of the vegetable kingdom we must not be too hasty in finding fault. It may be true that an equally good result would have followed if more rain had fallen; nevertheless, our ideas of what constitutes perfection in such matters are yet far from perfect. Let us, therefore, be thankful for the advantages a dry summer brings with it, and try our best to obviate some of the inconveniences arising from it in other ways.

That water forms an important constituent of every vegetable is well known and admitted; and products of rapid growth necessarily require much water, or they fail in arriving at perfection. Most of the products of the kitchen garden contain a large per-centge of water, and to obtain this, the plant sends its roots out foraging to a more distant locality if its ordinary domain be exhausted; but there is a distance beyond which the plant fails to extend its roots, and a more diminutive growth is the result. It is not, however, below the surface only that the plant seeks for nourishment, the humidity of the atmosphere and the night dews are alike grateful; and when these are less plentiful and there is less moisture in the soil, the less robust class of vegetation unquestionably suffers. Now, how to remedy this state of things has been for years a problem to the gardening world, but to say that it is solved in the present day would be wrong; for although something has been done, and very often indeed overdone (observe, I lay particular stress on this word), the result is not in any case

so satisfactory as where Nature does the work in her own way.

At the time at which I write (the middle of August), the appearance of vegetation and that of the atmosphere seem to point to a drier summer than we have had for several years. June, it is true, was not remarkably dry, but it was not a wet month; and the end of it, as well as the whole of July, and August up to the present time, has been exceedingly dry—so much so, that many sources from which water is usually obtained have failed completely; the larger streams and rivulets have rapidly subsided, and the smaller ones are, one after the other, drying up entirely. In many places where water would be an acceptable boon to vegetation it can scarcely be had in sufficient quantity to meet the everyday requirements of domestic use. Water, then, being so scarce, it behoves us to make the most we can of it; and unfortunately, where it is administered artificially in the way of supplying moisture to the roots of plants, it is often given in too great a quantity at one time or the reverse. It rarely happens that anybody watering a given plot of ground applies anything like the quantity that Nature would supply in the shape of rain; besides which, the advantages which a good watering gives are often lost from the soil being exposed to the sun, when that caking and hardening of the surface takes place which is alike injurious to vegetation and unsightly to the eye. All newly-planted surfaces should be covered, to prevent this caking and to retain the moisture; but it is my intention to advert rather to the quality of the water used than to the treatment of the soil after it has been applied.

Whatever may be the class of plants to which it may be necessary to give water, there cannot be a question that the moisture which Nature supplies in the shape of rain is most beneficial in every respect: passing through the air more or less rapidly, it absorbs certain gases, which are evidently essential to the well-being of the plants on which it falls, and the matters with which it is charged are alike grateful to the foliage of the plant and to its roots. Next to rain is water of a similar kind which has recently fallen and not been polluted by admixture with other substances, which rain water not unusually is when the roof on which it falls or the vessel receiving it presents anything which it can hold in solution. I have known a newly made tank turn water exceedingly hard and render it unfit for domestic use, and, of course, unfit for the requirements of plants also; while sometimes the roofs of certain buildings contain matters equally obnoxious. Mere soot arising from coals is not by any means the worst substance with which it comes in contact, although, except in certain cases, I am not aware of any good it does. Roofs and tanks are not the only causes of contamination in rain water, for sometimes in ponds when formed in clay containing a pernicious substance, this is imparted to the water. Clay is not by any means of so pure and innoxious a nature as is sometimes supposed; neither is sand, for I have seen a kind of coarse gritty substance that had nothing par-

ticularly poisonous in its appearance, and yet it would kill deep-rooted weeds when laid on a pavement or other place where they were. Of course, no one would think of using water coming in contact with a substance like this. Certain salts also abound in some soils, which render the water falling on them far from beneficial to vegetation. Therefore, taking all cases into consideration, it is perhaps more seldom than most people are aware that rain water is preserved in store in anything like its natural purity.

Although water from tanks, reservoirs, or ponds is sometimes impure, it is nevertheless most grateful when Nature denies us the refreshing influence of rain. Next to rain water is that from streams and brooks that has been duly exposed to the air, and which does not injure the vegetation among which it passes. River water is often turned to good account in irrigation; and happy are they who, in the dry scorching weather of the present season, have a stream sufficiently elevated above them to insure a supply for more urgent purposes. River water is, however, not always innoxious. Sometimes it is charged to an undue extent with iron, in which case the bed on which it runs is red with rust, and such water can only be safely administered to such plants as delight in a soil in which iron is found in abundance—as to Rhododendrons, for instance; but for domestic uses, I believe such water is by no means improper, and it is, perhaps, more wholesome than that containing chalky matter. It should, however, be more sparingly used amongst plants than water of another kind, if such can be had; although, perhaps, it is as good as the generality of well water, and much less hurtful than some of it is when used direct from its source.

Well water ought to be used very sparingly, and not at all for watering delicate plants, until it has been exposed to the atmosphere for a few days in any open vessel, the more shallow the better. It not unfrequently happens, however, as in the present season, that well or spring water is the only kind to be had, and that even that is far from plentiful: hence it becomes necessary to soften it by exposure before using, which, as above stated, is best done in shallow vessels, or, if in deeper and larger, then longer time will be required. In whichever way water is exposed, it is hardly necessary to remark that in periods like the present, with the dry arid atmosphere acting upon it, a considerable loss in quantity will take place: but this cannot be avoided; and as water must be had for the purpose of furnishing newly planted things with moisture to start with, every care should be taken to economise as much as can be what supply there is. A careless labourer, thinking that excess is liberality, will pour more water into the heart of a newly planted Broccoli than would serve a dozen, and repeat the same dose in a day or two, never thinking that the roots of the plants he is operating on are thus placed in a temperature like that of February, while the top is enduring tropical heat. It would certainly be better where practicable to use warmed water. If well water must be used let it be heated to the temperature of the atmosphere, and, after watering a plant with it once, let the latter be surrounded with dead moss, leaf mould, or very short dung for a time to keep in the moisture, which ought not to be allowed to escape.

Although the present season will call into use all the contrivances that can be had to assist in retaining moisture in the ground and saving water, and potted plants will not be so much overwatered as they sometimes are, yet I expect when an impartial retrospect is taken of the season that there will be found many things to be thankful for, and as a whole that it may be pronounced a beneficial season, not abundant in vegetables perhaps, but fruits will be plentiful, and the condition of the trees for another year promising. Some weather prophets that I hear of have taken up another theme, and are predicting that we are to have no more Potato disease, there being none this season, and they have hopes of its being eradicated. Certainly the dry weather has preserved the Potato crop from disease so far, and from it I have good hopes of the disease not making its appearance in the crop of 1864.

I may add, in conclusion, that although water is an essential element for vegetation, yet when applied by other than natural means it loses half its value. It is best to imitate Nature, and when it appears that a good watering is required, let it be done when rain is falling, assuming, of

course, that the quantity of the latter is not likely to be sufficient. Shading the ground by some artificial means is also beneficial, and at the same time not allowing any crops that are at all likely to withdraw nourishment from the ground to remain on it a day longer than necessary. The same rule holds good with regard to thinning crops; and in fact anything and everything that will tend to retain moisture in the ground and obviate the necessity of watering ought to be taken advantage of, so that the latter need only be resorted to when it can no longer be done without. J. ROBSON.

EXPERIENCES OF A COUNTRY PARSON.

"—Delectando pariterque monendo."

I SUCCEEDED to the livings of Rushton and Rawston, adjoining parishes, in 1852. They were united, not at my request, by act of Parliament. I am not a vicar, as stated by friend "D," but a pluralist Rector, the last, I believe, that was ever made. The churches are about 800 yards apart. Both are small and in good repair. The Rushton church, newly done up before I came, has more marks of antiquity than any other church in the diocese.

To Rushton, then, I came in the August of 1852. I had been accustomed to farm a little at Moor Critchill when curate, and also as tenant of my kind friend Mr. Sturt. I served the church, since rebuilt in magnificent style at Mr. Sturt's own expense. The new church stands on the site of the old church, in which George IV. worshipped when he resided at Critchill. As my two glebes are the keys of my patron's farm, the only one, at Rawston, and of my friend Mr. Sturt's farm at Rushton, I did not think it right to take the land into my own hands, more especially as it would have greatly inconvenienced the tenants. I had lived long enough to know that when a sacrifice is to be made the clergyman is the proper man to make it, and that, however distasteful at the time, in the end he will be a gainer, in the satisfaction he will feel in not having disengaged those whom he has to instruct.

Having been accustomed to "vegetation" all my life, for two years I felt like a fish out of water. What was to be done? What shall I, in leisure time, turn my hand to? At last I said to myself, "I will have a 'go' at gardening." Here, however, a difficulty met me. The old gardener had been here twenty-eight years, and had fixed his tap roots deep down into the soil. We all know that a gardener likes to have all the farmyard manure, called here "spit dung" (preterperfect of spade), and that he does not like giving up ground; still less does he like "master" trying his hand at things in which he has signally failed for twenty-eight years. His name was Elias Maidment, commonly called "Lias" here, and "sleeps well," I believe, deeply lamented by the parson and all the parishioners. I buried him in 1856 under a lofty Chinese Arbor Vitæ in Rushton churchyard, and put a noble Portland stone at his head, with the names of his past employers. These words may be seen on the slab:—

"An honest man's the noblest work of God."

"I pray thee let me go over, and see the good land that is beyond Jordan, that goodly mountain, and Lebanon."—(Deut. iii. 25). From this text I preached his funeral sermon.

We all know that gardeners like having their own way. As to arguing with some of them, that is lost time; you might as well argue with the pump at Aldgate.

In 1856 my brother was high sheriff and I was the chaplain. Before starting I went down into the garden and found Elias pruning the Gooseberry bushes, and shouting at real or imaginary bullfinches. He had had a bad sore throat for some days. The easterly wind was piercing; so I said, "Lias, go home, and get into bed, and have some tea; for if this easterly wind catches you by the throat it will bring on inflammation of the lungs, and in your weak state you will be gone quickly." "Oh no, that's no odds," was the reply. I went my way. After hearing sentence of death passed on Hannah Brown for the murder of her husband, which greatly saddened my brother and myself, I returned and found Lias in the last stage of inflammation of the lungs. Venous congestion had set in, and he was the colour of a copper-coloured Indian. I had barely time to say a

short prayer and call his wife up to my house, where he died (having received every attention), when "Lo! he was gone."

This leads me back to answer the question, "What shall I turn my hand to?" I said to Lias (in 1854), "Could you not give me up that bit of ground, as we have had no Strawberries for two years, and let me try my hand?" "Oh, that's no use. I have been here twenty-eight years and could never grow them; the soil don't suit 'em. It's impossible!" But there, master can please himself." "Impossible," said I, "is not English, and I will have a 'go.'"

Though the soil is mixed with chalk, and rests on chalk, I have never found any "impossibility" whatever. I have had immense crops this season. The Frogmore Pines were as big as Myatt's Surprise.

So far as regards Strawberries. The following relates to Peach trees, and is somewhat amusing. I could never beat into Lias's head that without protection by sheets in such a situation it would be impossible to grow Peaches. Before, however, I come to protection I have painful operations to describe.

"Lias," said I one day to him (he had a comic face, and his eyes nearly came out of his head), this is St. Thomas's Hospital. These patients must undergo amputation. Get the saw and hatchet, and the spade and pickaxe. I am going to cut these old naked trees down, and cut off all their perpendicular roots and make new trees of them. It will be a bloody job; hemorrhage may set in. Let's have a pint of beer each, for it's nervous work." The beer being disposed of I said, "Now don't be unbelieving. Job says, 'There is hope of a tree if it is cut down that it will sprout again.'" "Sprout again!" said he; "if ever *they* sprouts again I'm a Dutchman!" "Phoo!" said I, "prepare for operations. I am Sir B——, you are Stiggins the operator." "Oh, well," said he, resignedly, "what must be must be!" "Now," said I, "don't be nervous; give a decisive blow right through the 'crurum tenus,' avoiding the 'femoral artery.'" He gave tremendous chops, bordering on the spiteful: and, after the limbs toppled down he burst into a loud fit of laughter and exclaimed, "I'm blest if that aint the cruel *tenus*; and the female artery," he added, "with a vengeance." "Well," said I, "Stiggins, you shall have half-a-crown."—(N.B., no oil is so effective as palm oil.) I got him after this to cut the other two trees down, and also to cut off all their strong perpendicular roots, some of which were as thick as my wrist, and also to cut off the superficial roots in a radius of 30 inches round the stump. The ground was then renewed; and when the trees reached the top of the nine-feet wall and touched each other, I gathered, the first year of sheet-covering, over a thousand Peaches. I never before had as much from the whole wall as would fill my hat. From that time to this (eight years, including this), I shall, after taking its present fine crop of 560 Peaches, have gathered over 4000 Peaches, or an annual average of 500 Peaches for eight consecutive years! The trees are beautiful for strength, for new wood, foliage, and crops. The 560 Peaches now on the trees (I believe Royal Georges), are swelling fast and reddening. Since I have been writing this article two visitors, hearing of them, have called to see them, and expressed wonder and admiration. I have forgotten the year they were cut down. The old man died, I believe, in the March preceding the landing of over 1000. This was an unwise crop, as in the next year the trees only bore 197 from being overcropped. I am feeding the present heavy crop with strong beer grounds over the whole surface of the ground, which I never move, washed in with great inundations of water. They are copiously syringed every day at eleven o'clock to cool the wall, to refresh the wood and clean the leaves, and to keep down pests. Suffer a few words in conclusion.

1. Peach trees must be fed. What you take out must be put back. Every third year renew the surface with fresh maiden mould. The Peach trees of England die from too much disbudding, starvation, and neglect of the general health of the tree in winter and summer.

2. The leaves, when first breaking, are as tender as the blossoms. They must be protected by sheets or glass. Cold piercing winds injure the leaves, and ill health sets in. I had only twelve blistered leaves last year—only four this year.

3. The Peaches should be thinned as soon as you can feel

the little Peach in its sheath. They should be thinned at three times. 1823 were first taken off this year from the three trees, and 847 left on. There are now 560. These will come to perfection.

4. Peaches drop their fruit from immaturity of wood, previous over-cropping, want of water, especially at stoning time, over-cropping, over-heating of the walls, and from starvation.

5. You must, till frosts are over, keep the leaves and blossoms dry.

6. Keep the wood as close at home as you can, and beware of letting the trees become bare at the base and centre. Spur the fore-wood, and keep the rest of the tree like a shrubby Calceolaria. Winter may be severe: therefore keep on plenty of wood to select from. I will be answerable next year to put a Peach wherever the reader will make a chalk mark.—W. F. RADCLIFFE, Tarrent Rushton.

FLOWER SHOWS.

If the old saying that "too many cooks spoil the broth" be correct, then has the stew of the Royal Horticultural Society a very fair prospect of being spoiled—no, that would not be correct considering the condition in which things are at South Kensington, but of being made utterly useless; but the state of affairs there has opened up a wider subject; and the whole question of flower shows, their present condition, and their future improvement, have come upon the carpet. Having had some little experience in this matter, I venture, even although Sir Joseph Paxton and others have written upon it, to suggest a few things, not so much by way of alteration, but to check, if it may be, any tendency towards an ultra-democratic movement in the matter, and to throw a little conservative element into the question. I do not pretend to speak with authority; but it is open to every one who takes the trouble of observing to give the result of his observations, even though they may be those that have passed through the minds of many besides himself, and may not, therefore, have the appearance even of novelty.

The first question that meets us is, What is the object of a flower show? Is it to afford an agreeable promenade for the upper classes of society? Is it to replenish the coffers of a treasury exhausted by other outgoings? Is it to put money into the pockets of a few large growers who are sure to exhibit wherever they can? I have no objection to any or all of these views of a flower show. I delight to see the array of beauty and fashion that one is always sure to see at a metropolitan show. I have no objection to a society making money by flower shows, if it can be done, and I think our great growers deserving of all encouragement, although I do not for a moment believe that they are great gainers by their prizes; nay, I feel confident were they to put together the expense and trouble of growing the plants, and the expense of sending them to the Show, that they are at a loss. But I contend that none of these are the primary objects of a horticultural exhibition. It is to encourage gardening and gardeners, to show what skill, and energy, and perseverance can do, and to enable those who succeed in the various branches of the science to show the results of their labours; and I believe that where a society keeps this prominently before itself it is best fulfilling the objects for which it professes to work.

I know that it is objected to this that the very magnitude of the results obtained renders people hopeless of ever attaining a like degree of perfection. A gentleman sees, for example, some of Mr. Henderson's or Mr. Meredith's wonderful Grapes, and he contrasts them with his own miserable bunches, and he wants to know why he cannot have as good. Well, perhaps Robinson or Jones has not seen the said Grapes, but he hears of their size and beauty; and if he be a wise man he will tell his employer, "I think, sir, you would hardly like to incur the expense that has been entailed to procure this fruit; but if you do I am quite ready to try my best." Well, he does not reach the standard set; but he inquires the method of culture, gets Thomson on the Vine or some such book, and his viney bears a totally different appearance. The same holds good with regard to flowers. Take Mr. Bailey's Pelargoniums. It would never

suit a grower of small means to attempt such plants—a few of them would soon fill a house; but is there any one who has ever seen them that does not, when he is growing his plants, have them in his mind, and endeavour to improve the appearance of his plants by adhering to this model? Far, very far behind they are, but the exhibition plants have acted as the stimulus, and he is all the better for having seen them. Where, then, a society has the means within its reach, there flower shows ought to be encouraged and made to embrace within their limits the various branches of in-door and out-door gardening. The distinction that is often made between stove and greenhouse plants and florists' flowers, and that to the injury of the latter, is, I am sure, a mistake; and it is a gratifying thing that at the last great show of the Royal Horticultural Society the Princess of Wales paid most attention to the cut flowers, and requested Mr. Turner of Slough, and Mr. W. Paul, to send her their Roses, &c., which were accordingly forwarded to Marlborough House. This by the way.

I return to the statement I have made, that the one object to be kept in view is the advancement of horticulture; and if a society be honest in that, although it may make mistakes and oftentimes fail, yet I believe it will be looked kindly upon by all who value the benefits of gardening. And, as we look back on the last thirty years, who is there that does not see the immense advance in horticulture—an advance which I for one do not hesitate to lay entirely to the floral exhibitions held in London and other places? I hope to resume this subject, one of so much importance, next week.—D., *Deal*.

GREENHOUSE BUILDING.

I WISH to build a span-roofed greenhouse (not a viney), the length to be about 30 feet, would you kindly tell me what would be a suitable width, having reference to the stands for flowers, borders for plants and climbers, and walk for the ladies? What would be the best mode of heating it, and how can the furnace, boiler, and outlet for smoke be managed so as not to disfigure the structure, as it is to stand in the middle of a grass garden detached from every other building? Do you recommend the house to run north and south or east and west? Lastly, what might such a house be likely to cost built in a plain inexpensive manner within ten miles of London, Dublin, or Cork for example?

I am open to any suggestion as to size and style of building, heating, &c., and shall be much obliged for such.—J.C., A Subscriber.

[The matter has been treated on largely in previous volumes, but to oblige you we will give a few hints that may be useful.

First, For a span-roofed house 30 feet long, the necessary breadth, to admit of borders for creepers, stands for flowers, and walking room for ladies, must depend on the internal arrangements. When the fashions change 3 feet might form a suitable pathway—at present the walks ought to be at least from $3\frac{1}{2}$ to 4 feet wide, and even then would be of little use for such dresses as we have seen sweeping an eight-feet walk from side to side. Now, for an economical house, you could hardly do better than adopt something of the same style as we described as existing at Kimpton Hoo (vol. xx., page 55). Supposing the house to be 12 feet wide, we would make the height of the apex 8 or 9 feet, and the height at the sides, half glass, from 5 to 6 feet, ventilation being effected either by glass, or by openings in the wall below it. No better plan for ventilation at the top could be given than by having a double ridge-board, a space of 9 or 10 inches between them, and these supplied with ventilators on pivots. This would require an open cowl over them to prevent the wet entering. The next best plan would be to have a double ridge-board and a cowl coping, which could be raised by a lever. We are supposing that in this house the walk is down the middle, and 4 feet in width, which would leave you room for 4 feet of stage on each side. That stage might be a flat table of the necessary height, or slope from the side walls to the walk as at Kimpton Hoo, or the slope might be given without any stage at all by placing rather tall plants at the sides, and the dwarfest next the pathway. This makes a capital arrangement, and the beauty

of it is, that almost every plant comes under the eye, instead of above it as in most arrangements. We ourselves have to place plants to be looked up to, but there is not then half the charm that is enjoyed when you look down on them. Some years ago we described the gorgeous effect produced by the masses of bloom in the conservatory at Dyrham Park (then under the care of our able coadjutor, Mr. David Thomson) when looked at chiefly downwards from the drawing-room glass door. Mr. Cox, at Kimpton Hoo, manages to obtain a good deal of the same effect in his little greenhouse. The plants at the sides, being the highest, act as a background, and the lowest close to your feet bring all under the sweep of the eye, without straining it to look up. This, we think, would be your simplest arrangement, and, for a small house, perhaps the most effective. Whether with a flat stage or sloping stage or no stage at all, there would be ample room below the stages or below the pots, for a border for creepers, and it would be as well, perhaps, if each of them were planted in a wooden or brick box—in either case, the box need never be seen; but planting thus, instead of in a made border, would enable you to change your climbers and replace them without interfering with those that pleased you.

Considering the simplicity of details, ease of ventilation, &c., we do not think you could better this; but if you wished to have a central stage to stand opposite the doorway at each end, and a pathway round it, then your house would require to be 10 or 12 feet in height at the apex or ridge, 6 feet at the sides, and from 16 to 17 feet in width, and we would arrange it thus: In the centre, a platform 7 feet in width, and 3 feet from the ground, a pathway round it of $3\frac{1}{2}$ feet in width, and a stage all round the sides and ends, except where the door is, this stage being 18 inches wide and 30 or 33 inches from the floor. Such a house would give you much storage-room beneath the stages, and the skirts of the paths might be edged with Mosses and Ferns. Such a house, however, would cost much more than the more simple one, and we question if on the whole it would look better. In both cases the path could be partly occupied with dwarf plants when room is a matter of importance, and these could be cleared away when they would incommodate ladies and their extended dresses. We state this because such little hothouses soon become crammed and their fair mistresses will not dislike wrapping their skirts closely in preference to injuring their favourite plants.

Secondly, As to the best mode of heating. For such an arrangement as the last, the best mode would be by hot water, and more especially if a heat of from 50° to 55° and upwards were wanted in winter. For the simple plan first proposed, and where a medium heat of 40° to 45° in winter would be deemed sufficient, we would decidedly for such a single house adopt the flue system. We would carry that flue beneath the central pathway, either a single wide one of 15 or 16 inches, going from the furnace to the other end, or a double flue of 9 inches, outside measure, going and returning; but in either case the flue should be deep enough to permit of a thin covering of tiles, and then the top of the flue to be of tiles, flagstones, or whatever material of a conducting character formed the pathway. One advantage of this plan would be that in cold and damp days in winter, when the fire was burning, the ladies might always walk in the greenhouse with the certainty of having, not damp or cold, but a mild heated medium beneath their feet. For simplicity and economy in such a house, to be kept temperate merely in severe weather, we would prefer the flue to any other mode of heating; and if a single flue through the house we would build the first 10 feet with brick on bed, instead of brick on edge. If hot water, with its greater expense for fuel, &c., were resolved on, any middle or small-sized saddle-back or conical boiler will do; the simpler the construction the better.

Thirdly, As the building is to stand in the centre of a grass garden, how least to disfigure the structure with furnace, smoke-outlet, &c. Well then! in the first place we would not disfigure the place with any appearance of a furnace or stokehole. If the ground slopes at all we would have the furnace at the lowest end, and this would be best if you adopted a single wide flue or hot water. If on the level, it would not matter at which end the furnace were placed. Now, as you are not tied to 30 feet, but would wish to be pretty near it, we would have that length for the house

proper; but at the most appropriate end we would have some 6 or 10 feet additional as a lobby, looking the same as the rest of the house outside, but with a glass division and doorway in it, separating it from the other part. In one side of this lobby we would sink our stokehole, either for flue or hot water, and this we would cover with a wooden door, and over this you might set a table for plants, to be easily moved into the passage when the flue wanted looking to. This would effectually hide all appearance of a stoke-hole and furnace, unless to the initiated, and many things could be kept in this furnace-lobby in winter. In summer, when no fires were wanted, it would look like the rest of the house. Now, as to the smoke-outlet, supposing that was wanted merely at one end, still, for uniformity, we would have an ornamental iron shaft, or one of terra cotta, or earthenware, somewhat ornamental, fixed at each end, and the pair would so balance as to do away with any idea of ugliness. They might also be connected with breaks and jutting-out along the ridge-board, so that the smoke column and its balancing neighbour would come in as necessary adjuncts. As for the smoke itself, except when lighting the fire, little smoke need be seen if broken coke is used, and a little air is caused to play over the fuel in the furnace. Of course, if smoky coals are used, there will be more difficulty in disposing of the smoke. By such means as indicated the chimney, or rather chimneys, will be ornamental rather than otherwise. Were it not for being so detached from any other building, no smoke at all need be seen. For a more extended greenhouse it might, in similar circumstances, be desirable to carry the smoke in a tunnel to the nearest chimney of the establishment. What we suggest has reference to the circumstances you describe, keeping economy, efficiency, and graceful uniformity in view. Many greenhouses are disfigured because they look like a pig with one ear; the other ear, or the appearance of the double ornamental chimney, would have pleased the most fastidious taste, especially of those who are influenced by the first appearance, and not by stern questions of utility. Either iron, somewhat ornamental, or earthenware tubes, not less than 9 inches in diameter, should be used as smoke-vents in such a house.

Fourthly, We would prefer such a house to stand north and south, instead of east and west, as the full morning and afternoon sun can thus be taken advantage of, and the hottest sun will strike the house transversely. The other direction will, however, do very well, and it will have one advantage standing east and west, that only the south side of the span will require shading. Mr. Cox does this efficiently at Kimpton Hoo by thin calico curtains inside, fixed by rings or pivots, which remain on in hot weather in summer, and can be easily taken off and replaced.

Fifthly and lastly, As regards expense we would rather not touch on it. That will be a matter for the designer and the builder when the plan is decided on. The more work, the more money; the more ornament, the more expense. You can easily ascertain what the glass would cost at 2d. per foot, the expense of sash-bar rafters, if the roof is to be fixed, which should be at least 3½ inches deep by 1½ inch across, also, the expense of glazing, the cost of walls per foot or per yard. The having a fixed roof will reduce the expenses very much, but then you cannot move the house without taking it to pieces. Making the roof in sashes will pretty well double the expense. We have had particulars of the five-pound curate's greenhouse, and the cheap wood-and-glass houses of Mr. Rivers, and our own experience leads us to the conclusion that that great gardener has not in cheapness exaggerated a jot. But beyond these simple structures, everything in the shape of durability and extra elegance must be paid for. The best plan for you to adopt after fixing on a plan, is to have everything done by a respectable builder when you have settled on the price. If you have a stone-mason or a bricklayer to employ, then a carpenter, then a glazier and painter; and then a hot-water man, you must expect to pay not merely for the workmanship, but for the superintendence of the work being done in each department. Not being in the trade we would rather not give prices; as, when we have ventured on this ground, and found ourselves pretty correct, some half dozen of letters would come, stating that we would ruin the trade, and another half dozen telling us the writers would willingly undertake such work at

a lower figure than we stated. Still the alteration of circumstances is so great, and the least departure from the simply useful so expensive, that it is much better that every gentleman should make an agreement for himself. Let him, however, well consider the matter, and have scarcely any deviations from the plan for which the estimate is given, if rigid economy is his object, as for each deviation it is only right that he should pay.—R. F.]

ROYAL HORTICULTURAL SOCIETY.

AUGUST 16TH.

FLORAL COMMITTEE.—This was one of the most interesting meetings of the season. Subjects for examination were unusually numerous. Mr. Chater's grand spikes of seedling Hollyhocks were in themselves a splendid exhibition. Mr. Chater had brought some of these seedlings on the previous Tuesday, under the idea that it was one of the days for the Committee's meeting. By the aid of a Sub-Committee and the Chairman, who were summoned to a special meeting for another purpose on that day, certificates were awarded, which will be noticed in the following report:—

The Rev. E. Hawke, Willingham Rectory, sent cut flowers of seedling Hollyhocks Willingham Defiance, light rose, bright colour—first-class certificate; Gladiator, dark maroon or ruby—first-class certificate; Cavalier, a carmine rose—second-class certificate. These were all very promising flowers. Mr. Payer, nurseryman, Folkestone, sent four seedling Pelargoniums—Charles Payer, Mrs. A. Payer, Giant Golden Chain, Folkestonii, far behind the class of flowers of the present day. Mr. Norford, Brompton, sent Verbena Purple Prince, a dwarf-habited plant, with very small purple truss; Mr. Turner, Slough, seedling Verbena Princess of Wales, very delicate white ground, with pale rosy stripes, by no means an effective flower; also one flower of a promising Hollyhock, Yellow Perfection. Mr. Bowie, Clapham Rise, exhibited twenty seedling Gladioli scarcely in bloom, nor did there appear anything extra or novel in them. Mr. Cooling, Bath, had a very pretty striped seedling Verbena, Annie, the best striped variety we have seen, pale pinkish ground, with broad bright rose stripe, which received a second-class certificate; and Tropaeolum Fire Queen, not distinct from King of Tom Thumbs. Mr. Bland, "Star and Garten," Richmond, sent a double Fuchsia, Charmer, deficient in colour as well as form; and Mr. Perkins, Coventry, Verbena Earl of Aylesford, bright scarlet, but inferior in every way to Lord Leigh and Foxhunter.

Mr. Chater, Saffron Walden, exhibited many superb spikes of seedling Hollyhocks, the only and proper way of showing their merits; for it is much more difficult to show a spike of good flowers than three good flowers selected from a spike. Spikes of several of the seedlings sent on the 9th were again brought for inspection. The following received first-class certificates:—Decision, a remarkably fine flower, buff, shaded with salmon; Rev. E. Hawke, salmon, suffused with rose, a very fine flower; Chairman, deeply-shaded cerise; Fanny Chater, a first-rate flower, rose tinted with carmine; Aeme, a seedling of 1863, had received a first-class certificate; James Allen, purplish puce, a most useful colour; Cygnet, the finest white ever exhibited. Second-class certificates were awarded to Competitor, rosy lilac; Othello, shaded maroon; Fairest of the Fair, deep rose. Two other seedlings—Rev. H. Dombrain, a salmon rose; and Cyrus, pale orange—were not noticed.

Mr. Chater also exhibited for the Rev. E. Hawke a spike of a seedling named Albion, a white flower faintly tinged with lemon, for which a second-class certificate was awarded.

Among Mr. Chater's cut flowers were Hercules, a fine full flower, yellow, shaded with fawn—first-class certificate; Rev. Joshua Dix, bright red, very fine in texture and colour; a seedling of 1863—first-class certificate; and among other seedlings we noticed Zeno, an orange buff; Millicent, a bright rose; Sanspareil, carmine rose; and Rubra purpurea. Such a collection of seedlings no individual has ever exhibited in one day; Mr. Chater must feel gratified at his success. In a collection of forty-eight cut flowers which received a special certificate were Peeress, Countess Bussell, Joshua Clark, Erebus, Royal Scarlet, Lady Dacres, Lady Paxton, Pericles, Princess, Invincible, Princess of Wales,

Glory of Walden, Rosea pallida, and many other first-rate varieties.

Mr. Porter exhibited eight seedling Hollyhocks, among which was Volunteer Improved, a nice compact dark ruby flower, and a second-class certificate was awarded for it. Messrs. Downie, Laird, & Laing sent seven seedling Hollyhocks. Some of these were very promising flowers, but not in a condition for their merits to be judged, having suffered much injury from the thrips. Stanstead Hero, a very fine flower, and others, will doubtless take a high position when seen under more favourable circumstances. A special certificate was awarded to Messrs. Downie & Co. for their collection of cut flowers, some of which were first-rate. We noticed Stanstead Rival, Lady Fuller, Joshua Clark, Charles Eyre, Scarlet Gem, Lady de Veaux, Orange Perfection, &c. Messrs. Downie & Co. also sent two fine specimens of *Amaryllis reticulata superba*, one bearing six and the other five beautiful flowers. This plant has been in cultivation for many years.

Mr. C. J. Perry brought five seedling Verbenas, two of which, Glowworm and Snowball, received second-class certificates at the last meeting. The others were Charles Turner, a very superb flower, large truss, blush ground, with very large rosy purple eye, the finest flower in its class—first-class certificate; Lilac King, a pale lavender, fine truss, and very sweet-scented, dark eye; and Queen of the Pinks. A collection of twenty-four varieties also came from Mr. Perry, and it received a well-merited special certificate. The flowers were perfect in size, form, and colour. Among them were Purity, Miss Harvey, Wonderful, Nemesis, Startier, Emperor, Magnificans, L'Avenir de Ballent, Modesty, &c. Mr. Perry also brought Scarlet Pelargonium Glowworm, pale orange scarlet, small truss. Mr. Bull contributed Verbena Otto of Roses, a flower remarkable for its perfume; Verbena Merry Maid, bright cherry, a pleasing colour for bedding purposes; also a collection of Italian striped Verbenas. The Rev. E. H. Charlesley, Iffley, Oxford, exhibited cut specimens of Verbena Una, a fine flower, but not sufficiently distinct from other varieties; and Mr. Keynes, Salisbury, several seedling Dahlias, some of which were very promising flowers. Among these were Edward Spary, dark plum, first-rate form—first-class certificate; John Salter, buff ground striped with scarlet, fine form—second-class certificate; Striped Perfection, a decided improvement in its class, dark maroon on a pale purplish ground—second-class certificate; George Rawlings, purplish puce—second-class certificate; Lady Maude Herbert, a very beautiful flower, pale lemon tipped with carmine—first-class certificate; and Hamlet, a dull red or velvety crimson, fine form—second-class certificate.

Mr. Eyles brought from the Society's Garden, Chiswick, specimens of plants recently sent home by Mr. Weir, three of which received first-class certificates—viz., a species of *Anthurium*, from New Grenada, a very handsome foliaged plant of the Caladium tribe; *Peperomia* species, and *Peperomia arifolia*; also a new *Dieffenbachia*, not sufficiently grown to decide upon its merits, excepting that it is very distinct from any other known *Dieffenbachia*.

A fine plant of *Peristeria elata*, presented some time since by Mr. Bateman to the Society, and grown in the gardens attracted much attention. It is a very singular and beautiful Orchid, known in its own country as the "Dove" plant, the centre of each flower most perfectly resembling a white dove.

FRUIT COMMITTEE.—H. G. Bohn, Esq., in the chair. Mr. John Keynes, of Salisbury, sent three bunches of a new Grape, introduced from Smyrna. The bunches are large and long, and, considering they were grown on a pot Vine, give evidence that when planted out the plant will yield immense bunches. The berries are large, ovate, with a thin, tough, white skin, and crackling flesh. They were not quite ripe, and the flavour was evidently not yet developed, so Mr. Keynes was requested to send it later in the season. Mr. Francis Dancer, of Little Sutton, sent a basket of very large Lord Suffield Apples, one of the largest and most valuable early culinary Apples. A seedling Apple was sent by Mr. Cooling, nurseryman, Bath, called Bailbrook Seedling. It was raised at Bailbrook, Batheaston, near Bath, and belongs to the Irish Peach class, a beautiful and very early dessert Apple, tender-fleshed, with a balsamic flavour. The Committee recommended it as worthy of cultivation as a handsome, early, dessert Apple, ripe in the beginning of

August; but the fruit exhibited on the 16th of August was considerably overripe, having already become mellow.

A seedling Plum was received from Mr. Thomas Ingram, of Frogmore. It is medium sized, mottled with purple and yellow. Flesh yellow, melting, sweet, and richly flavoured. The Committee asked that it might be sent again. Mr. Cooling, of Bath, sent a seedling Kidney Potato of a fine purple colour; but as the Committee could form no judgment beyond the appearance, Mr. Cooling was requested to send tubers to the garden for trial.

EFFECT OF GALVANISED NETTING ON FLOWERS.

A FEW days since a lady in Devonshire drew my attention to what appeared to both of us a very curious circumstance with reference to the effect produced by galvanised wire netting, when placed round a bed of flowers.

The bed in question contains Carnations—seedlings, which would, properly, come into bloom this summer—but, strange to say, the plants commenced blooming in the month of April, and have continued to produce a great quantity of flowers up to this time. This appears to be contrary to the nature of the plant; and, indeed, a bed of the same kind of plants close at hand, but without the wire netting, has only bloomed in the regular season. Those within the netting have almost, and in a few cases quite, exhausted themselves with this apparently forced blooming, having made little or no grass, and many plants having actually died. The netting is, I think, 18 inches or 2 feet high, and is placed there to keep off rabbits.

Can any of your practical readers give us any account of similar experiences, or can those who may possess scientific information assign any cause for the phenomenon?—DECIDEDLY PUZZLED.

A CHEAP GREENHOUSE AND STOVE.

By any one who has a mechanical turn, a greenhouse or stove can be erected and heated at a less cost than one would think. Having all along had a fancy for the cultivation of plants in-doors, I have tried many a shift, but with poor luck, and the expense of putting up a house to answer my wants was, I thought, out of the question. However, in one of our newspapers, I observed the advertisement of a carpenter who wished to dispose of a lot of windowsashes, sound in glass and wood. These I inspected, and finding them suitable, closed with him at 1s. 9d. a-piece for the lot. I immediately set to work, and made the frame of a size to fit my sashes, and in a very short time the whole was completed, painted, and made watertight. I may mention, that over the junction between the two sashes on the roof, I nailed roofing felt cut in strips, which costs a mere trifle, and the sash-bars were cut with a saw to allow the water to run freely away. Although I wield the pen as an occupation, still I can also handle the saw and plane, and the use of these one can easily acquire by a little practice. I have seldom met with an amateur gardener who could not handle them to some extent.

Heating was the next difficulty. I first tried steam, as I was in possession of a small boiler for driving an engine in connection with a turning lathe which I had. This would not do. Steam could not be kept up all night. A stove was next tried. This would have done well enough could I have superintended it personally, but I had to be at business all day, and it was by no means pleasant to come home and find it at a cherry red heat outside. It was keeping up the temperature with a vengeance; and then the dust from the clinkers, even with the greatest care, would fly about. My patience was at last exhausted, so I resolved to adopt the hot-water system, and purchased one of Riddell's stoves, with a coil of one-inch piping inside. Each end of the coil is brought out of the casing and screwed to fit a coupling. To this I added a foot more of tubing, and connected them with the flow and return pipes going round the house by tapered oak plugs driven up with red lead into the four-inch pipes, and a hole bored in the centre, admitted the screwed end of the one-inch tubing coming from the stove. A better

or cheaper joint could not be had, as it has been in use for more than a year, and is as good and free from leakage as the day it was first put in.

For fuel I use what are called gas cinders, which are the burnt gas coal that is drawn from the retorts, and which can be bought for about 5s. a-cartload. If a strong fire is desired, it will yield that to perfection by giving draught, and on the other hand nothing will smoulder so long with so little air. As a proof of this I refer to my note-book, and find that for fully more than a month my fire was never rekindled, and then it was only owing to my absence from home that it went out. It may interest some to know how this is done. You are aware that in these stoves of Riddell's the fuel is put in by a circular aperture (fitted with a cover and made tight with silver sand), in the top of the stove. Now so soon as I have the heat up, and a clear fire, I open the cover, and fill up the stove nearly to the top with the cinders, close the ash-pit and front doors (the latter used for lighting), and then plaster these all over with wet ashes. Perhaps some one may be able to explain better than I can the reason why the fire burns at all. In the morning I open the small front door, and with a bent piece of iron remove all the burnt fuel till I see the clear fire. I then open the top cover and press the unburnt fuel down to the furnace-grate, and close up as formerly. If this is done I can insure any one having little trouble in the management of that class of stoves. I may add that this treatment will not do with common coal, as it requires a fair supply of air to yield the required heat, or even to smoulder. I can speak from experience on this.

My house is about 24 feet long, and about 8 wide, divided into a stove and greenhouse. The sashes cost me, I think, including all the wood I required, £3 10s.; hot-water stove, £4 10s.; pipes, £1. I find common rain-water pipes answer perfectly well, and being thinner than others heat more rapidly. I coat them with common blacklead dissolved in water to the consistency of paint, and laid on with a brush or piece of flannel; one pennyworth of blacklead will go a long way. The joints of the pipes are filled in with hemp and redlead.

You will see the cost was £9, but, of course, my time was a good deal occupied after business hours, but it was altogether a labour of love on the part of—**AN AMATEUR MECHANIC.**

[The smallness of the cost is entirely owing to the bargain you made, obtaining the articles much below cost price, and thus it hardly forms a guide for others. When all the materials have to be purchased at their fair value, the fixed roof will always be the cheapest, and sashes will be dispensed with; but then for tenants such houses are not easily moveable. We consider you deserve credit for the way in which you have made the best of the materials. We have no doubt that with personal attention you would have succeeded in heating to your satisfaction, either with an iron or a brick stove; but all these matters require care. We are obliged by your experience of Riddell's stove. It will answer better for securing the requisite temperature in the two divisions of your house. We believe every word you say about the fuel. We presume that what you call gas cinders are not the burnt gas coal drawn from the retorts; but such, or coke, used again once for heating the retorts, and then called cinders. Such are generally in small pieces, possess good heating power in furnaces, and emit little smoke. We are obliged by all your details.]

HOTHOUSE NEAR THE SEA.

I AM thinking of building a hothouse on the slope of a hill, facing south-east, but the piece of ground is within 200 yards of the sea, and is exposed to winds coming from the south and east. It is entirely sheltered from the north by the hill. My object in having a hothouse is to make it remunerative as well as pleasant. Now what perplexes me is, whether the sea breeze is much colder than the land breeze, and whether the house would be very much more expensive to heat on that account. I am living in Jersey, where it happens that there is not one hothouse built close to the shore, and therefore there is no one to give me the results of his experience. Will you, therefore, kindly

offer me a little advice on the subject? It would be a serious loss for me to build one, and then to find that the extra expense for fuel would, in a great measure, swallow up all the profits. Coke is 7s. a-load, coals 18s. per ton.—**PERPLEXITY.**

[We should not like to advise you in the circumstances without knowing how far the sea vapours and spray may be carried in your exposed position. It would be a serious thing to build a house for profit in such an exposed position, and some stormy night or day to find the salt spray coming into your house. Of course much might be done to prevent that, by close glazing, and ventilating chiefly on the northern side, or that not exposed from the sea. This would be our chief reason for delaying and making some experiments. The cost of the fuel need form no drawback—that is if you can take it easily to the place. The sea breeze in the position will be warm rather than otherwise. We have known hothouses do well at a shorter distance from the sea than you are, but then a bluff headland intercepted the spray, whilst you seem fully exposed.]

VISITS TO GARDENS PUBLIC AND PRIVATE.

CAMLIN, THE SEAT OF JOHN TREDENNICK, ESQ.

On the banks of the river Erne (which from its issuing from the lake of the same name at Beleek to its entrance into the Atlantic has a fall of about 170 feet in about five or six miles), stands a house which from my earliest days I recollect to have heard of as one where gardening was diligently carried out, and successfully too; and I was the more anxious to see it, inasmuch as the old-fashioned notions of horticulture were still cherished there, and everything had not been made subservient to one modern innovation—an advantage of which I think few can estimate the importance when climatic influences have to be combated. I have oftentimes seen in Ireland gardens which are perhaps very foreign to modern notions, but which always gave and do give me the notion of great enjoyment—well and abundantly stocked with fruit of all kinds, with an abundant supply of vegetables, and then a green sward with a shrubbery at one side or in the centre, with beautiful shaded walks of Yews, Laurels, or even deciduous trees, inviting to meditation, and suggestive of comfort and ease in the sultry days which sometimes visit these northern regions. Of course, all this is most heterodox in the eyes of those who consider that everything ought to be *en règle*, and that uniformity (beds matching beds, colour, and height, and shape all alike), is that alone after which we ought to strive. But just look at the advantage in such a season as this. What are grass gardens now? I have seen many a one lately, and, as might be expected, green is the very last colour one sees in them. Many of the beds are only half filled with flowers; and in these bright glaring days the brilliant reds and yellows are anything but pleasing to the eye. In fact, for those who have been advocating a mixture of the old and modern systems of gardening this has been a most opportune season, affording them many a fulcrum by which they may move their object.

The gardens at Camlin may be divided into three portions, of which the walled-in one contained as magnificent a crop of fruit and as fine a collection of vegetables as are to be found anywhere. And here let me say I was very much surprised to find how very little difference there was in the state of forwardness between the north-west portion of Ireland and my own extreme south-eastern portion of England. Strawberries were all, or nearly all, over; Gooseberries and Currants ripe; Cherries, the later sorts still to be had; Apples and Pears, &c., in much about the same condition; and yet we certainly have a much larger share of sun and warm weather than they have, although the variations of temperature are not so great: and this is probably the reason of their productions not being so much retarded as their position would lead one to imagine they would be. There is but one large viney where Grapes are forced, and well too. (And talking of Grapes, I forgot to mention in my account of the Rockville Gardens that Mr. Bewley entertains the notion that in order to obtain flavour and colour a different system should be adopted. He consequently keeps his house closed even during intense sun, running up

the thermometer to 120° during the day, and ventilates freely at night, thereby, of course, reducing the temperature immensely. He himself speaks favourably of the results, and nothing could be more evenly beautiful than the crop I saw in the house when I was there.) The whole of the large garden, comprising several acres, was kept in excellent order, and well repaid the care and attention that had been bestowed upon it.

Close to the house, which has been almost rebuilt by the present owner, is a grass garden; and it will, I am sure, gladden the heart of "A WILTSHIRE RECTOR" to know that this is one place in which "King Croquet" has been dethroned; for though wherever one goes quiet little lawns and grass gardens are gradually usurped by his most despotic majesty, the lawn here, which was used as a croquet ground, has been cut up into beds, and the mallets, and hoops, and balls banished to wait the time when some other convenient place can be found for them. The beds were well filled; but unfortunately that terrible frost that occurred on the last night of May played sad havoc, and many of the beds had to be filled again, so that there was a deficiency of bloom. One bed I particularly noticed as seeming to be a very nice relief to the brilliant colours which are generally the rule in such gardens; it was entirely composed of the Variegated Alyssum, which is used oftentimes for edging, but in this way it was to me a novelty and a pleasing one. There were the usual plants that we see in our modern system; and one can have no objection to it when, as here, the old friends are not thrown on one side for these new faces.

Alongside of this, but separated from it by a wire fence, is another piece of ground, partly shrubbery and partly garden, in which is a very fair specimen of the Nesfield style of gardening. It is a long but somewhat narrow steep, composed of a series of small beds, in which are planted some of the lower-growing bedding plants, while different coloured gravels, &c., are added. It was a combination of the two styles, and better, I think, than a rigid adherence to the system of oil-cloth patterns, which have justly excited so much ridicule; yet the effect has been obtained by great trouble and considerable expense, and, after all, I question whether it is at all worth it. I know that Mrs. Tredennick regrets much that many of her old favourites have been consigned by the gardener to oblivion to make room for his plants.

Roses seem to flourish here. Some of the standards were of great size, and the character of the soil tends to bring out their colours well. A bed of Moss Roses at Fort William, just opposite, was of the most luxuriant character, and showed clearly how admirably the soil agreed with them. There were not many of the newer sorts, but those good varieties which are to be found in the garden of every Rose-fancier.

I do not intend to intimate that Camlin is what is called a show place, but it is a very pretty place; and the traveller from Enniskillen to Ballyshannon would do well to stop for a few minutes and ask permission, which will be freely granted, and I do not think there will be much regret for the delay it has occasioned.—D., Deal.

MANCHESTER GOOSEBERRY SHOW.

How few of our readers know how a Gooseberry show is conducted; and the majority of them when reading of any kind of horticultural exhibition, immediately see, "in the mind's eye," raised stages, formally arranged plants, and batteries of red flower-pots. There are no such concentrations of things odious to good taste at a Gooseberry show; there is no attempt at display; everything looks like business, and every one present seems to mean it.

The very hostelry where this Manchester Show was held is in good keeping with the exhibition; it looks like a resort of business, and its sign, "The Falstaff," shows the rotund knight much belike an animated bloated Gooseberry, such as we saw there on the 6th day of August last past. Along the centre of an upper chamber a table was placed, on each side of which sat earnest men, the majority of whom had each a box enveloped in a handkerchief, and guarded by his resting elbow. At the top of the table sat two officials,

rendered grave by a consciousness of the power delegated to them. Before one of them was an accurately adjusted balance, and a long array of weights, from a single grain to that of many pennies. This was the decider of each berry's excellence in heaviness. By his side sat the recorder of each berry's weight submitted to the balance; and from his book—the chronicle of Gooseberrydom—there is no appeal.

Gooseberries are divided into four classes, distinguished by their colour—the white, green, yellow, and red. A berry is called for in a class—say greens. Some one takes a berry from its cotton envelope in his box, its weight and ownership are ascertained and recorded; another and many others follow in the same class, and it is found that William Jones's *Thumper* is the heaviest. "Has any one a berry that will beat that?" A pause, and then a sly old fellow unfolds the cover of his box; there is a general shuffle of excitement as he produces his Gooseberry from its cotton wrapping, and hands it to the weigher. All heads bend towards the balance. It is heavier by five grains than *Thumper*, and Thomas Smith's *Conqueror* is placed as the prize berry of its class in the exhibition box.

This box has a solid bed of plaster of Paris within it, and oval hollows are scooped in that bed ready for the repose of the victor berries. One Gooseberry was announced to weigh 33 dwts. 19 grs.

NORTHWICH GOOSEBERRY SHOW.

LIST of prizes awarded at the Gooseberry Show, held at the Angel Inn, Northwich, Cheshire, July 30th, 1864:—

EXHIBITOR.	NAME.	dwt. gr.
Mr. F. Yates, Maiden Prize (Kettle).....	Leveller.....	20 4
Mr. G. Beckett, Twins (Pruning Knives).....	London.....	45 10
Mr. J. Johnson (Premier Prize £1)	Antagonist.....	34 4
Mr. W. Jones (Steward's Prize, Copper Kettle).....	London.....	31 2
Mr. G. Beckett do. do.	Leveller.....	26 7
Mr. T. Lanceley do. do.	Shiner.....	28 4
Mr. C. Leicester (Macclesfield) do.	Postman.....	27 0
Mr. T. Nicholas (Steward's Prize, Brass Pan).....	Lord Liverpool.....	25 9
Mr. R. Foster do. do.	Drill.....	25 22
Mr. J. Jones do. do.	Telegraph.....	27 4
Mr. C. Leicester (Plumbley) do.	Antagonist.....	26 12
Mr. F. Jameson (Steward's Prize, Tea Pot)....	Lion's Provider.....	25 6
Mr. T. Bull do. do.	Seedling Mary Ann.....	28 12
Mr. Joseph Wynne do. do.	Thumper.....	25 21
Mr. G. Plant do. do.	Freedom.....	21 18

RED CLASS.

Mr. F. Jameson.....	London.....	29 23
Mr. W. Jones.....	Beauty.....	27 0
Mr. T. Lanceley	Flixtona.....	26 16
Mr. T. Lanceley	Highlander.....	26 4
Mr. C. Leicester (Plumbley).....	Duke of Sutherland.....	25 22
Mr. J. Johnson.....	Lion's Provider.....	25 18
Mr. J. Johnson.....	Give it a Name	25 4
Mr. J. Wynne	Clayton.....	24 18
Mr. T. Lanceley	Slaughterman.....	24 12
Mr. G. Plant	Wonderful.....	24 10

YELLOW CLASS.

Mr. J. Johnson.....	Leveller.....	28 18
Mr. J. Beckett	Oyster Girl	25 4
Mr. W. Jones	Tinker.....	24 14
Mr. G. Plant	Drill.....	24 12
Mr. C. Leicester (Macclesfield)	Trumpeter.....	24 10
Mr. J. Johnson	Peru	24 6
Mr. F. Jameson	Leader	23 12
Mr. C. Leicester (Macclesfield)	Australia	23 10
Mr. F. Jameson	Catherina	23 2
Mr. J. Jones	Cramp	22 22

GREEN CLASS.

Mr. Charles Leicester (Macclesfield)	Jerry	27 8
Mr. J. Johnson.....	Stockwell	27 6
Mr. J. Johnson	Norcliffe	26 4
Mr. W. Jones	Thumper	25 15
Mr. T. Lanceley	Shiner	24 12
Mr. J. Wynne	Telegraph	24 8
Mr. C. Leicester (Macclesfield)	Sir G. Brown	24 6
Mr. G. Beckett	Bravo	23 18
Mr. C. Leicester (Macclesfield)	Rough Green	23 6
Mr. J. Johnson	Gretna Green	22 18

WHITE CLASS.

Mr. W. Jones	Antagonist	27 3
Mr. C. Leicester (Macclesfield)	Mitre	26 12
Mr. J. Wynne	Snowdrop	26 6
Mr. J. Johnson	Freedom	25 22
Mr. J. Johnson	Carless	25 4
Mr. T. Lanceley	Hero of the Nile	24 18
Mr. C. Leicester (Macclesfield)	Jenny Lind	24 0
Mr. F. Jameson	Snowdrift	23 15
Mr. J. Johnson	Overseer	23 12
Mr. W. Ryley	Queen of the West	23 8

BUSH APRICOTS.

THE Apricot being a favourite fruit with me, I read with interest the article in No. 177. Six years ago, come November, I planted two very young trees of the Breda variety as bushes, and they grew so vigorously that when four years had expired, they each of them measured fully 10 feet in height, and as much across, although rather severely pinched and cut back. In the third and fourth years they blossomed abundantly, but would not set fruit. About this time your contributors and readers spoke out. Some complained that they could obtain no fruit, and Mr. Rivers advised that the trees should be turned into firewood. I had at that moment come to the same conclusion (spring of 1863), and had commenced cutting one down; but when about to sever the last leader of this fine bush, a fit of compassion seized me. I trimmed neatly the mutilated parts, lifted the tree, and replanted it in another place. It bore and ripened fruit the same year, and the untouched companion bush also produced a heavy crop of delicious fruit. This year they both bear a light but serviceable crop.

The description of De Jonghe's Sweet Kernel Apricot closely agrees with the Breda. Is it better, as a more sure bearer? or should I do well to plant De Jonghe's Diamant? At the present time I have scarcely any wall to use, and am glad of bushes that succeed, as they take no gardener's time. I can manage them myself, which I love to do. The Apricot is a delightful companion all the growing season; beautiful in blossom, beautiful in its lively and luxuriant foliage, and not less so when occasionally adorned with its golden fruit.—CHARLES ELLIS, *The Orchard, Upper East Sheen.*

[Until the new varieties which you name have been grown for some time in this country, it would be impossible to answer your questions with certainty.]

AMONG THE WELSH MOUNTAINS.

"I SHOULD like to visit Wales if it were only to see the *Sambucus niger*, the plant said to be always found near old cottages, placed there by their first owners to keep away the witches." So said a fair young lady not long since. "You may remain at home and see it," was the reply; and a spray of Elder was fetched from a neighbouring hedge.

This is not quoted merely for the purpose of noting that the Elder is usually found near old cottages in Wales and elsewhere, and that it might have been placed there for anti-witchery purposes, or because a favoured wine is made from its berries, or a cosmetic from its flowers; but the conversation is quoted as an example of things being sought for at a far distance which might be obtained close at hand—only because we do not know better.

Take another instance. Englishmen go abroad in search of the grand and the beautiful, yet the writer of this has ascended Table Mountain at the Cape of Good Hope; has done the same among the rocky mountain passes of St. Helena; and he has threaded his way among the jungled hills of Sumatra. From all the lofty elevations of those far-off lands he has looked upon Nature in some of her grandest and most beautiful aspects; and now he records his experience that their equals—their equals fully—are in the mountain districts of North Wales.

This is written sitting in a window looking down the lakes of Llanberis, or, as they are here called, Lyn Padarn and Lyn Peris. The densely wooded feet of the mountains Yr Altwen and Coel Mawr are on either hand coming down to the lake's edges, and would have been bathed by the waters but that a road has been cut around the margin. Nestling in these mountain woods peep out a few white-walled cottages; in the distance, where the waters of the lakes commingle, and on a rocky prominence, stands that castle of many mythic tales—Dolbadarn; and beyond that, towering as if in emulation to excel in height, are Glyder fawr, Mynydd fawr, and Snowdon.* In the garden borders near him are in full bloom surpassingly fine specimens of Fuchsias, Dahlias, and Hydrangeas—the latter blue-flowered without the aid of the gardener. Truly this mountain-enclosed valley is a combination of the grand, the beautiful, and the

* Glydyr fawr is 3275 feet high; Mynydd fawr, 2393; and Snowdon, 3570.

cultivated, which may be often equalled but cannot be much excelled.

Other lessons, however, are to be learned among the Welsh mountains, and they shall be jotted down, though small details are felt as a descent after sweeping over such a grand total.

The present year has given birth to a cry against hotel landlords that has swollen into a mania for joint-stock-company hotels; whereas it would have been wiser to encourage those landlords who manage their establishments liberally, make their hotels enjoyable, and charge moderately. If asked where such are to be found, I reply there are many such in North Wales; and two at once rise upon my memory—the hotel at Capel Curig, and the Penrhyn Arms at Bangor. Moreover, they are surrounded by gardens thrown open to visitors, well ornamented with flowers, shrubs, and trees, and preserved in order such as is only usual in private establishments.

Not far from the Penrhyn Arms, which I would select as a model hotel, occurs that model village, Llandegai. I visited the place to see the tomb of James the First's Lord Keeper, Archbishop Williams, but was far more gratified by the entire village. Every cottage, built of stone and slated, is a model of cleanliness and perfect repair; every hedge is Quick, uniform in height, and scrupulously clipped to a pyramidal form; every cottage has a garden, and every garden is fully stocked and well cultivated. Every cottager is tidy; and I visited the place more than once, attracted by the appearance of comfort and contentment which seemed all-prevalent; and it is no exaggeration to say that I felt the happier for looking upon a place where labour and respectability, utility and perfect order, are so intimately combined.

Cottage gardening there is pursued under favourable circumstances. Lord Penrhyn is its patron, and a sheltered valley contributes alluvial soil and a genial temperature; but I have seen gardening in North Wales pursued under no ordinary difficulties.

At Capel Curig I strolled up a mountain side to an elevation on which clung a plantation. Hazel had there been combating with the elements, and was worsted in the struggle. Birch, however, defied the winds and other mountain severities; and just above them on a ledge of the mountain was imbedded a cottage. It has even a name in the ordnance map—Bryn Engyn. I could say much about the simple manners and kindness of its tenants, but they chatted only in Welsh, and so we could only telegraph by nods, and finger-pointings, and smiles, there were no frowns needed. Well, in this region of Birches was a small garden, with a wall needfully high to protect its tenants, which were Gooseberries, Black Currants, Cabbages, Carrots, Potatoes, Turnips, and Peas, just ready (August 6th) for use—a tall late sort. Nothing could be said in commendation of the horticultural skill displayed, but the produce of the vegetables was a full average, except of the Carrots, and they would not require this exception had they been sufficiently thinned.

Good gardening, however, or gardening of any degree of merit or demerit, does not characterise North Wales; but it is satisfactory to notice that there is such a prevalent taste for botany among tourists, that there are residents who specially announce their readiness to aid in guiding to the localities where rare plants dwell, to assist in naming and mounting them, and to supply specimens. As examples, there is Mrs. Sykes, at Llandudno, and "John Roberts, Botanical Guide," at Llanberis. The latter has a greenhouse in which he has for sale potted Ferns, natives of the vicinity, and the list is not scanty.

Whoever intends to ascend Snowdon, should do so from Llanberis. There is no more either of difficulty or danger in accomplishing the ascent from thence, than there is in ascending any steep, stony bridle-way, for the road is only traversable on horseback or on foot. So little is the difficulty, that an invalid lady, incapable of walking anywhere without support, reached with me the extreme summit of Snowdon, mounted on a mule, and aided by that most attentive and careful of guides, Elias Roberts, brother of the "Botanical Guide." The supply of "Snowdon ponies" is ample—sturdy, sure-footed beasts, not to be urged out of what they know is a safe, short-stepped walk, by any amount of persuasion, verbal or whackamical; and if the

tourist, in addition to the aids we have mentioned, can secure rooms in that hostelry where cleanliness, kindness, and economy preside—Thomas's Snowdon Valley Hotel, but which deserves to be called “The Tourist's Home”—he may be sure of a combination of “traveller's joys” rarely attainable.

One gentleman, suffering from acidity temporarily, not constitutionally, I hope for his own sake, told me that, “mounting up Snowdon was going a long way with nothing to see when you got there!” This is not the place to dwell on views having for their outlines the mountains of Ireland, Isle of Man, Westmoreland, and Cheshire, with foregrounds such as Salvator Rosa and Poussin loved to draw, but the botanist will agree with me that on and about Snowdon there is something “to see when you get there,” if he will read this list of its rare plants.

<i>Alisma natans</i> (Floating Water Plantain).	<i>Lycopodium alpinum</i> (Savin-leaved Club Moss).
<i>Anteribium serotinum</i> (Spiderwort).	<i>anotinum</i> (Interrupted Club Moss).
<i>Arabis hispida</i> (Alpine Rock Cress).	<i>selaginoides</i> (Prickly Club Moss).
<i>Arenaria verna</i> (Spring Sandwort, and two varieties).	<i>Oxalis reniformis</i> (Kidney-leaved Mountain Sorrel).
<i>Aspidium ionchitis</i> (Rough Alpine Shield-Fern).	<i>Papaver cambricum</i> (Welsh Poppy).
<i>Asplenium viride</i> (Green Maiden-hair Spleenwort).	<i>Parnassia palustris</i> (Grass of Parnassus).
<i>Campanula rotundifolia</i> (Round-leaved Bell-Flower—one-flowered variety).	<i>Poa alpina</i> (Alpine Meadow Grass).
<i>Carex atrata</i> (Black Sedge).	<i>glauca</i> (Glaucous Meadow Grass).
<i>curta</i> (White Sedge).	<i>Polygonum viviparum</i> (Alpine Bistort).
<i>rigida</i> (Rigid Sedge).	<i>Polyodium avicinum</i> (Hairy Alpine Polypody).
<i>Ceratium alpinum</i> (Alpine Mouse-eared Chickweed).	<i>phegopteris</i> (Pale Mountain Polypody).
<i>latifolium</i> (Broad-leaved Mouse-ear Chickweed).	<i>Pteris crispa</i> (Curled Brake).
<i>Cnicus heterophyllus</i> (Melancholy Thistle).	<i>Ranunculus acris</i> (Upright Meadow Crowfoot).
<i>Cistopteris alpina</i> (Laciniated Bladder-Fern).	<i>Rhodiola rosea</i> (Rosewort).
<i>Cochlearia groenlandica</i> (Greenland Scurvy Grass).	<i>Salix herbacea</i> (Least Willow).
<i>officinalis</i> (Common Scurvy Grass).	<i>reticulata</i> (Wrinkled-leaved Willow).
<i>Draba incana</i> (Twisted-podded Whitlow Grass).	<i>Saxifraga ajugaeifolia</i> (Ajuga-leaved Saxifrage).
<i>Eupetrum nigrum</i> (Crowberry).	<i>hypnoides</i> (Moss Saxifrage).
<i>Festuca vivipara</i> (Viviparous Fescue Grass).	<i>oppositifolia</i> (Purple Alpine Saxifrage).
<i>Gallium boreale</i> (Cross-leaved Lady's Bedstraw).	<i>rivalis</i> (Clustered Alpine Saxifrage).
<i>Habenaria albida</i> (White Satyrian).	<i>stellaris</i> (Starry Alpine Saxifrage).
<i>Hymenophyllum tunbridgeense</i> (Tunbridge Filmy Fern).	<i>Serratula alpina</i> (Alpine Sawwort).
<i>Isoetes lacustris</i> (Lake Quillwort).	<i>Silene acaulis</i> (Moss Campion).
<i>Littorella lacustris</i> (Plantain Shore Weed).	<i>Subularia aquatica</i> (Water Awlwort).
<i>Lobelia Dortmanna</i> (Water Lobelia).	<i>Thalictrum alpinum</i> (Alpine Meadow Rue).

The employment of guide to the dwelling-places of these plants is one of danger, for many of them are found on the ledges of some of the most precipitous rocks. In walking through the Pass of Llanberis, I turned aside into the burial ground of its very plain little church, and one of the first epitaphs I could read, for the majority are in Welsh, records the death of William Williams, “for more than twenty-five years botanical guide at the Victoria Hotel, who was killed by a fall from Clogwyn y Gwedd, June 13th, 1861, whilst pursuing his favourite vocation.”

Not many yards from this epitaph is another, preserving the remembrance of an event which caused a general painful sensation at the time of its occurrence. I need add nothing to these its details.

“Sacred to the memory of the Rev. Henry Wellington Starr, B.A., Curate of All Saints, Northampton, who perished on Snowdon while on a tour through North Wales, September 15th, 1846, aged thirty-two years, and whose remains, discovered June 1st, 1847, were interred beneath this stone. An only son, and a faithful minister, he was universally regretted, and he left a mother and two sisters to mourn for life their irreparable loss.”

The monument bearing this inscription is beneath a very ancient Yew, from which the large lateral branches have been barbarously lopped; but a younger evergreen has been planted by the tomb, and, as is the prevalent custom, Box and other evergreens are arranged upon and around neighbouring graves. Even on the ill-cared-for resting place of the deceased cottage children mentioned in Wordsworth's touching lyric, “We are seven,” I found flowers were planted, though I wish the grave was better kept of these who, “in Conway churchyard lie.”—G.

NEW PEACHES.

EXQUISITE.—Through the kindness of the Rev. T. Collings Bréhaut, of Guernsey, we have been favoured with a specimen of this remarkable Peach. Last year we were equally indebted to this gentleman for a similar favour, but the specimen which we received this year far surpasses that sent us last.

The fruit is of immense size, being $10\frac{1}{2}$ inches in circumference, and weighing $9\frac{1}{2}$ ozs. It is roundish oval in shape, marked with a distinct suture, and terminated at the apex by a sharp nipple. The skin is yellow as that of an Apricot, with a dark crimson mottled cheek on the side next the sun. Flesh deep yellow, veined and stained with deep blood red at the stone, tender, melting, juicy, rich and vinous. This is a noble Peach, and one of delicious flavour.

Mr. Bréhaut says—“I had it from Mr. Rivers in 1860. It fruited in 1862, on the 25th of August; again in 1863, on the 21st; and now it will be ripe about that time as you see. The tree itself has very yellow leaves and wood, and grows fairly, but I do not consider it prolific.”

EARLY ALBERT.—This we received from Mr. Rivers, of Sawbridgeworth, whose seedling it is. The fruit is above medium size, roundish, frequently with one side of the suture higher than the other, and pitted at the apex. Skin greenish yellow, covered with crimson points on the shaded side, and deep crimson becoming sometimes almost black when grown against the wall, and fully exposed. Flesh white, with a faint brick-red tinge next the stone, from which it separates freely, very tender and melting, and with an abundant sugary and vinous juice, which is very richly flavoured. A delicious early Peach, ripe about the middle of August.

CULTIVATION OF THE MELON.

(Continued from page 133.)

SINCE hot water circulating in iron pipes has been employed for heating horticultural structures, the old-fashioned system of growing Melons on beds of fermenting materials has been to a great extent superseded. It is decidedly a less troublesome, and a more certain method of applying artificial heat, and has given an impetus to horticulture, especially to that branch of it relating to the cultivation of plants from warmer climates; and I will now proceed to treat of the application of hot water in iron pipes, and of hot air by smoke-flues, to the cultivation of the Melon, whether in pits without trellises for the shoots to run upon, or in larger and loftier houses.

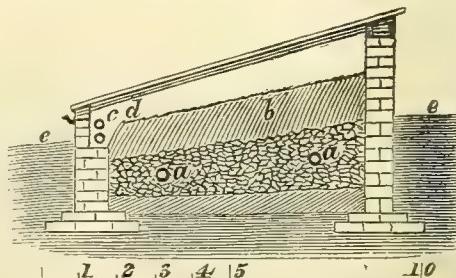

Fig. 7.

Fig. 7 shows an ordinary pit heated by two hot-water pipes, *a a*, for bottom heat, which are surrounded by rubble, such as half bricks, &c., from 6 to 9 inches of the same being placed above them; the rougher parts of the compost are then put on, or a layer of charred turves an inch thick, so as to prevent the finer soil from passing into the rubble, and on that from 10 inches to a foot of soil, *b*, in which the Melons are planted in the centre of the bed. They are trained over the soil in the same manner as those in dung frames. There are two four-inch hot-water pipes in front, at *e*, to maintain the proper degree of atmospheric heat, the soil being kept from them by a slate on edge, *d*. *e e* is the

ground level. Except in being heated by hot water the pit does not differ from an ordinary one.

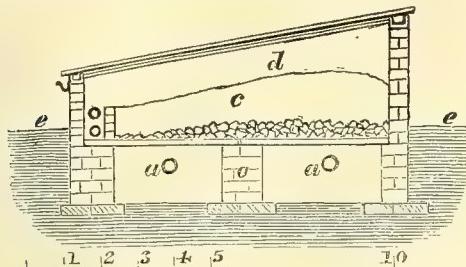

Fig. 8.

Fig. 8 is the end section of a pit heated by hot-water pipes, differing little from the preceding, except in the bottom heat being supplied by two four-inch pipes to a chamber, *a a*, the soil being supported above by flagstones, which also form the upper cover of the hot-air chamber, two of their ends and sides rest on the outer walls, the other on pillars of brick or stone as *o*. The flags are not laid in mortar but have the joints open. A few inches of rubble placed on the flags prevent the joints from becoming choked with soil. There are two four-inch pipes in front for top heat, *c* is the space for a thickness of 1 foot of soil, and *d* the space for the plants; *e e* is the ground level. This mode of furnishing bottom heat to Melons—viz., by hot-air chambers, is preferable to placing rubble over the pipes as in *fig. 7*, or soil immediately in contact with the pipes. The heat is more equable by the chamber system, and communicates to the soil above a much lower temperature; but the heat is greatest by the other plan immediately above the pipes, whilst the remaining parts of the soil are nearly cold. By the chamber system there is a large volume of heated air of an equable temperature throughout, presenting the same evenness as a bed of fermenting materials. There are more ways of communicating top and bottom heat for Melons, but these two are the best that I know of. In fixing the pipes it is advisable to have those for top heat flows, and those for bottom heat returns.—G. ABBEY.

(To be continued.)

ORCHARD-HOUSES.

In retiring from this controversy I cannot but think Mr. Abbey would have been wise to have dropped the subject instead of reopening the question. What does he wish to prove, or what impression does he wish to produce before retiring? Is it that he did not advocate open walls heated by flues for the production of Peaches in place of orchard-houses? Your Number of April 19th will settle that question. Is it that he cannot grow Peaches without fire heat? Few will be disposed to doubt his evidence in such a cause. Is it that no one else can grow Peaches and Apricots without fire heat? Scarcely, one would think, whilst every year Mr. Rivers and myself advertise when our fruit is ripe, and invite all the country to see it. Is it that the fruit is inferior when grown under glass? Of course it may be if badly grown, if the trees are covered with red spider; but is it necessarily so? This is what is so trying to our tempers, that people who know so little of the subject should reiterate such nonsense time after time. Mr. Abbey says, "An Apricot from an orchard-house is of a sickly colour all over." Why, he never can have seen one. I have some now better in flavour than he or any one else ever ate from a wall, and as handsome in colour as an Apricot can be, equally ripened all round, and like a sack of honey in texture, and Mr. Rivers has had this year pecks of such fruit. Then with regard to Peaches, my man has just sent in a Grosse Mignonne, which has fallen off a tree growing in the old orchard-house with boarded sides and ends, and with an open ventilating space, which cannot be closed, under the eaves all round; it weighs nearly half a pound, and is one of many like it left on the trees. If Peaches and Apricots are not superior when grown in an orchard-house to those from an open wall, what

are we to think of the moral character of those who have eaten the thousands we have given away? I have never yet heard one who said he or she had eaten as good from a wall, and I have refused 7s. a-dozen for a whole houseful of Peaches, that I might give all who came an opportunity of judging. All that I would contend for is, that what is easy to me ought not to be difficult to any one worthy of the name of a gardener.

Mr. Abbey says many orchard-houses have failed. There is no doubt of it; what other kind of cultivation does not fail in many places? I was shown three good vineyards some time since with twenty-three bunches of Grapes in the three houses: successful Grape-growing is too common for the system to bear the blame in this instance. I had a gardener here only yesterday who said his crop of fruit was quite equal to mine, and his trees as clean and healthy, who failed miserably the first year. He acknowledged he had not half watered his trees the first season, and they were eaten up with red spider; he took more care of them afterwards, and for two years the trees have been all one could wish. I said, "Well, what do you think of the system now?" "Why," he said, "I hope to have another house soon, for I take more pleasure in the orchard-house than anything else." I do not like to mention names of private individuals without their leave, but as the place is only six miles from here I will undertake to show it to Mr. Abbey. Within a mile or two of this place I can point out several houses where the gardeners failed the first year, and never afterwards. If trees are but kept clean and healthy there is less difficulty in fruiting them every season. This, as well as greater experience, is sufficient to account for success. Many of my best trees have been ten years in pots.

But are there no cases of constant failure? I am happy to say I only know of one in this neighbourhood. A gentleman in the north of this county built a good house, I think three years since; when his gardener received the plants which had been pinched during summer and were full of well-ripened buds, he cut most of them down to improve them. Of course the first season was a failure. During that summer he refused to pinch the trees, "he had grown Peach trees before, and knew all about it." The house was like a Willow holt, full of long unripened shoots, many of which were cut down again in spring, and there was a very small crop the second year. The third summer I met the owner, who told me he had a better crop, but not at all what he expected; I told him it was more than I expected if he had any improvement to report. But he asked, "What would you advise me to do?" I have a few trees with a good crop upon them, and should like them to be fine, how ought my man to treat them? I told him my man had just top-dressed ours with a mixture of horse-droppings and malt dust, and he would repeat the dressing in July. The gentleman told his gardener what he had heard. In a day or two afterwards this Solon in a blue apron took out several inches of soil, quite baring the roots, and placed this hot stimulating manure in immediate contact with them! Of course all the fruit and most of the foliage dropped off, and so ends act the third—three seasons lost. The gentleman was advised when next he top-dressed a grass field to pare off the turf first, and he acknowledged it would be a parallel case. There are many men who will never learn this or any other new system of cultivation. If they were in a position to see it every day, they would in time learn it as they learnt all they know, by what is termed rule of thumb, a rule which requires very little causality.

I shall always hold that success is the rule, non-success the exception, in all cultivation under glass, where talent is united with industry. Where climate and moisture are under control there is but little room for excuses. After many years of experience I can honestly say the orchard-house is all, and more than all, I hoped for. In a bad cold district hot-water pipes may be necessary—here they are not required—to get better fruit, with certainty, every season, than we can ever produce on walls.

When houses are built for each kind of fruit, and Apricots, Peaches, Plums, Cherries, &c., are grown separately, a new era will have commenced in gardening; and when 300 square yards can be covered with a house fit for a nobleman for a little more than £200, who can doubt such will be the case? In a short time men will be found writing that there is

nothing new in orchard-houses, as we are now told there is nothing uncommon in producing Grapes in January. By-the-by, I was on the Committee when those new and old Grapes were exhibited; and though most of us voted for the old Grapes, because the competition was for flavour alone, and the new ones were unripe, yet all agreed that the new ones were worth three times as much in Covent Garden, even in their then state.—J. R. PEARSON, Chilwell.

HOTBEDS.

I HAVE just been reading "A Gossip about Hotbeds," and the advice given is very good. About twenty-six years ago I lived with an old squire as gardener, and had the management of a three-light and a two-light pit. One day I went out about two miles to see a friend who was gardener at an old hall. He had two ranges of pits, each consisting of six or eight lights. His Cucumbers and Melons were just beginning to show fruit, but the plants had sunk down too far from the glass, and he said to me, "Next year I will try the soil on boards." I pondered over the remark, and in the following March I filled my two-light pit about three-parts full with worked manure, putting in posts in the corners and ledges, in order to keep the boards at about 20 inches from the glass. The pits, I must observe, were badly situated, being on a rising ground and exposed to north winds, and when I put my plants in, the wind cut them at the back if I gave air, and if not the steam was too much for them. I found I had not sufficient heat for that early period of the season, so I put linings all round, sunk 2 feet beneath the surface. I thus obtained more heat and also more steam, and my plants looked worse and worse. The thought struck me one day, I will knock out half a brick just below the boards, about the centre of the front wall. I did so, and the steam came pouring out like smoke from a chimney, and in a few days my sickly yellow plants began to grow freely, assuming a dark green colour. I have pursued the same course ever since and never found it fail.

A farmer near here who has a two-light frame has tried the following plan for six years and he is always successful:—He takes six or eight cartloads of fresh dung from the stable, places it under a south wall just outside the garden, builds it square to the height of about 3½ feet, beats the top level, then takes two boards about 10 inches wide and an inch or two longer than his frame, and places one about the centre of his bed, which is from 1 foot 8 inches to 2 feet wider all round than the frame. On each side of his centre board he places strips of old board, old stakes, bean rods, old gate bars, or palings, leaving intervals of an inch or two for the steam to rise through, these strips only extending an inch or two wider than the frame all round. This done, he next puts on his cross-bars which are about the thickness of a strong hedge stake, and their ends being cut flat these rest on each side of the centre board for about 2 inches. He then puts on his other centre board so as to cover the ends of the cross-bars, and thus there is an interval between the two boards which acts as a flue for the escape of rank steam. He then rests on each side of his top board another lot of strips like those at the bottom, and if a little closer together all the better. If short of strips he puts on a few Raspberry cuttings or stout straw. This stage is about 8 or 9 inches above the level.

Having made this framework he packs a lot of short dung all round it, and puts on 2 or 3 inches of rotten dung or clay, treading and beating it down so as to prevent the rank steam from going through. He puts on his frame and places 2 or 3 inches of dung or soil up the sides, so when the steam rises it works along the cross-bars and escapes by the steam fine along the centre. He next puts on about 9 inches thick of soil all over and treads it down. Sods 2 inches in thickness chopped up, some rotten leaves and rotten dung mixed together, form the best compost, a little sandy soil being placed at the top.

After making the sides of the bed even he drives in ten or a dozen thatch pegs round the edges, leaving the tops about 4 inches above the surface, puts long strips of wood just inside the pegs, and fills in with soil at the two sides and front of his frame. On the beds thus formed he sows Radishes and a little Drumhead Lettuce mired. The Radishes soon

come up, and when these are drawn the Lettuces appear, and if too thickly they can be transplanted into the garden. He then drives in six or eight thatch pegs round the hole at the back and puts some straw round the pegs, for this hole must be kept quite clear. He next builds some manure about 1 foot or 15 inches up to the wood at the back of his frame, and in a day or two the steam will be up; he obtains some Cucumber plants from a neighbouring garden, plants them in the frame, and with proper attention he can have Cucumbers ready for cutting in about three weeks. Last year he had a good supply from May to the middle of October.

The advantages of this plan are, that there is no danger of over-watering; that the plants are generally covered with dew as in the open ground, at least on the under side of the leaves; that when the Radishes and Lettuces are off the roots of the Cucumbers strike into the soil on the outside, getting the benefit of every shower of rain; and, finally, that on a keen windy day the frame can be kept close without the plants being injured by the steam of the bed.

If Radishes, &c., are not wanted the manure can be brought up to the sides of the frame, when a bed is made up much earlier. Cuttings of all kinds do well. I generally cut Cucumbers in the last week in March. One season I cut ripe Melons on the 27th of May. Potatoes do exceedingly well. In working brick pits I never like to raise the linings higher than the soil inside, as they only require bottom heat to cause a steam in hot weather.

I have generally found the only plan to keep a good succession of Cucumbers in pits is to raise young plants from cuttings and pull up old exhausted plants, turning the earth as well as the linings before putting new plants in. I have always found a good depth of earth—say from 1 foot to 2 feet, advantageous for Cucumbers and Melons, especially in a very hot season, as the roots are not so liable to be scorched by the sun.

I have ventured to send you the above remarks, as I think every one should endeavour to impart to others as much information as he can.—E. MARSHALL.

We are very much pleased with your idea of doing all the good you can, and imparting all the information you can, even in a humble way. Were there more of your disposition there would be more knowledge, more happiness, and more progress in this world in which we live. We honour your resolve quite as much though we may not be able to perceive much of the novel or progressive in what you describe. Keeping the bottom of such beds at a uniform distance from the glass by means of boards has been long practised. When the flooring was made secure, either by priming or by earth firmly placed over them, dung less sweetly worked could be used beneath them. In other respects, except keeping the roots out of the manure little advantage was gained over the common bed and frame, for provided the right distance from the glass is secured, the frame will sink as the bed sinks. We think your boards were too near the glass; instead of 20 inches, 36 inches would have been better, which would have given you 20 inches for soil and 16 inches for foliage and air. You might have moderated the force of the fresh air by hanging a close net over the opening, and if only a little tilting—say half an inch or less were given, the heated air as it passed out would have heated the cold air going in. We have seen men planting Cucumbers in a windy day in March, with as little care as to their tenderness as if they had been planting an Oak on the open common. This was not the way by which the old gardeners performed such wonders with their dung-beds, and we feel persuaded you know how to admit air and keep out steam. The success attending the knocking-out of a brick in the wall, just shows that you had too much noxious steam, from the dung not being sweetened enough, and the boards and soil too open to keep it down, and also that most likely there was too much bottom heat to suit the atmospheric heat. In the "Gossip" you refer to, fermenting material was scarce, and the most was made of it, and no danger at all was experienced from steam, the operations too being much less cumbersome than those to which you refer.

Upon our own principle of following the plan that answers best, we advise you to follow yours, and would say to all with beds in brick pits, Adopt the same plan under similar circumstances. For ourselves

we rarely know anything about the effects of steam. All we want is the heat, and we have no difficulty in regulating it when obtained.

We have no doubt the plan adopted by your neighbour, the farmer, answers well, and if others try it we feel confident they will succeed as they ought to do. But with those six or eight loads of dung we think we could grow fine early Radishes without any trouble; and when they were done, we would take out the soil, turn out the dung, now pretty well sweetened, place as much more a little wrought at the bottom, and the materials of the first bed on the top of it, cover all with soil well secured at the sides, and as soon as that became warm turn out the Cucumber plants. Mind, we have no objection to the plan, but that it seems to require a great deal of doing, and we must confess we have little faith in such a steam chimney in a house as a substitute for fresh air. But, perhaps, we do not clearly understand the system. We see through all about the banking-up to keep any bad steam from rising, but we do not see so well the efficacy of the hollow chimney-mouth, &c. All danger from over-heating can be equally well prevented by making the bed much more shallow in the middle than at the sides, or what would come to the same thing, forming the bed there chiefly of faggots and prunings, or having a chamber underneath or flue to be heated by outside linings. We do not agree with you as to never having linings higher than the soil inside. Provided we have enough bottom heat, we prefer that the top heat should come chiefly from heating the sides of the pit and frame, instead of much through the soil. When we could not do this, we have run pipes through the bed into the atmosphere of the house, with the ends open, and by this means obtain heat without any steam. We have no doubt but that the system answers admirably with you when you obtain such results, and we and others feel indebted for your giving us this information respecting your practice. We also approve of the greater depth of earth for Melons than is generally given; but that will not do without sufficient heat. Of course, from July to October, in a warm season, Melons require little more heat than what the sun gives them. Could we make sure of sunny days we might pretty well dispense with dung heat and hot water too. The variable character of the climate renders either desirable when thoroughly under command.

—R. F.]

A GARDENER'S GRIEVANCE.

I HOPE you will give me a word of advice as to what I ought to do under the following circumstances.

I was till lately gardener to the rector of the parish I reside in. I had had my situation for more than two years, and had no particular fault to find with it, except that my master was occasionally in the habit of using language to me and employing epithets which were most painful to myself to listen to. I grant I was occasionally careless, but that was no reason why he should call me, as he sometimes did, "a donkey," or as he did on one occasion, "a conceited muff."

But, sir, I want to make you acquainted with the circumstances under which I left my situation, and to ask you whether I am not a very ill-used man. I will lay the entire case before you. My late master's garden, I must premise, opens into a field in which are kept three cows, and I was charged always to keep the gate, which stands between the garden and the field, carefully closed. I was generally very careful in this matter, but on one occasion, about three months ago, I left it open, and one of the cows found her way into the garden. My master was not pleased, as you may suppose; but as I told him I was very sorry for my carelessness he did not say much; but he reminded me, as I thought most unnecessarily, that I had once before neglected to close the gate, and he told me, as he had a right to do, that I must not do any such thing again. Well, sir, I said I'd be careful. But, unfortunately, about six weeks ago I neglected to close the gate as I came out of the field the last thing at night, and in the morning my master saw the three cows feeding on the lawn, and I am sorry to say that they had trampled down the flowers, and made sad work. My master called me to him, and showed a most unnecessary degree of temper in the matter, and spoke in

a way that I considered quite degrading to his character as a clergyman. He blew me up before the servant maids, and called me in their presence "disgracefully careless" and "unfit for my place;" and when I asked him what I was to do, the words he used were, "Why, you helpless dog, go and turn the cows into the field." We went together for this purpose, and when the job was finished, "Sir," said I, "it was hardly fair for you to expose me before the young ladies in the kitchen." "What young ladies do you mean, Jack?" he said, as I could see, very crossly. "Sir," I said most respectfully, "you just now spoke to me before the maid-servants; and though I can bear to be rebuked by yourself, sir, when no one is present, it is very hurtful to my feelings to be called names when young ladies are standing by and listening. How, sir, can I keep up my character in the kitchen if you are the one to let it down?" Whereupon my master laughed at me, and said, "Go and look at the garden, Jack, and judge whether I said a word more than you deserved." "I shouldn't have minded," I said, "sir, if it hadn't been before the ladies."

In an hour or two's time he was in the garden with his wife and two daughters, and, sir, the remarks I heard them make about me were more than human nature could well endure. As ill-luck would have it, in my confusion I had neglected again to close the gate, and one of the cows was just coming into the garden, and my master called out in a loud voice and said, "Look there, Jack;" and when I had closed the gate, he said in a sneering sort of way, "I suppose, Jack, I had better say nothing to you before the ladies!" And then the ladies laughed at something, I could not make out what. I could not speak, but I felt most indignant.

Well, sir, after I had tidied up the place, my friend, the under gardener at the hall, came on an errand from the Squire, and before he left I saw him, and asked his advice. I told him that my master had let me down before the maid-servants, and that he sometimes applied unseemly epithets to me; and he fully coincided with my remarks, and said he did not wonder I felt hurt; and when I went on to say I contemplated giving up my situation, he said that though he did not like men to give up places when they were in the main well off, yet that sometimes it couldn't be avoided; but he advised me to think well of it. However, on consideration, I determined to give my master a month's warning. When I had so done my master said to me (and mark, sir, how, even when in a good temper, he would not forbear calling names), "You are a silly fellow, Jack, and I hope as you grow older you'll grow wiser. But go to bed and sleep over it; and if you are tired of the place give me notice again to-morrow morning. If, however, you say nothing, I'll say nothing, if you are intending to be more careful for the future;" and then he said some more things, and I cannot say but that he spoke very kindly. However, on the following morning I repeated my notice, and my master said, "Very well, the greater donkey you; but mind, when you repent it, that it is your own doing, and not mine." When I told my friend, the under gardener at the hall, he said it was not pleasant to be called a donkey, and that a clergyman should know better. In a few days' time, sir, I heard, to my intense disgust, that this under gardener had applied for my situation, and was coming in my place!

Now, sir, was not this most unhandsome, and a violation of all professional etiquette? And, sir, my master told a gentleman who wrote for my character that I was a good servant; but he spoiled it by saying that I was sometimes careless; and, sir, I am not yet engaged. But, sir, my conscience assures me that I have acted right, and I hope that you will agree with me in thinking that if masters would keep their servants they should forbear from all such remarks as are calculated to wound their feelings, especially before female servants, who are commonly sufficiently impertinent without the opportunity being given them of hearing one blown up for any trifling act of negligence which any one is liable to. Nor was this the first time of my master's having done so; he did it last January, when the fire was out one morning in the greenhouse, and he said some plants were killed by frost. However, I was very sorry, and said nothing; but one cannot bear to be put upon too often.

I hope, sir, you will pardon my intrusion, but I am sure that as your publication is "for gardeners," you will not

refuse to give me your opinion and advice as to the circumstances I have laid before you.—J. M.

[You seem to have acted very stupidly by so repeatedly leaving the gate open, and very foolishly in leaving a very kind and indulgent master.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

ATTEND to seedling and newly-planted crops with water, and look over our former directions as to bringing up any arrears which, more or less, generally occur at this season. Keep a sharp look-out for the larvæ or grubs of a species of cockchafer, which at this season do considerable injury to newly-planted crops by eating off their roots. Carrots and slices of Mangolds may be stuck in the ground, when the insects will attack them and may be destroyed. *Cabbages*, no further delay should be allowed in sowing for a main crop. *Celery*, attend to the earthing, and when the attacks of slugs are apprehended, dust in lime about the plants before closing the earth around them. *Herbs*, collect them for drying, and on no account allow vegetable seeds to remain exposed after maturity on the parent plant. *Lettuce*, Brown Cos and hardy Cabbage should be sown for spring use; prepare a piece of ground in a sheltered situation, and plant out that sown last month. *Onions*, lay the tops; in cases where the crop is affected with mildew, ripen the bulbs as soon as possible, and select the worst for early use. *Spinach*, sow for late winter use.

FRUIT GARDEN.

Crevices formed between the soil and walls are the favourite lodgments of numerous insects; therefore, at this season the soil adjoining walls should be frequently disturbed. A shallow trench may be taken out all along, and as this is being proceeded with, the soil adhering to the bricks should be removed with a hard broom. The portion of the wall thus exposed should be sprinkled with lime water, to be used the instant it is made. Remove all superfluous shoots from wall trees, and expose the fruit of Peaches and Nectarines; but this must not be done by cutting off the foliage. If the foliage in any case is overcrowded the remedy must consist in the proper regulation of the shoots. Place dry bean stalks, cut in lengths of about 6 inches, among the branches, and by that means most of the earwigs may be caught before the fruit becomes ripe. Spread short grass or other soft litter beneath Peach and Pear trees to receive chance-falling fruit. Cut out the old wood from Raspberry plants, leaving only about six of the strongest shoots of this year's growth.

FLOWER GARDEN.

Look over rock plants, pruning back any that are over-growing choice kinds, in order to give them sufficient time to break before winter. Cuttings of choice plants, such as Saponaria ocymoides, Onosma taurica, Linaria alpina, Phlox setacea, &c., should now be put in for planting out in spring. Keep such plants cut back as have a tendency to overgrow Box or other edgings. Peg down a few shoots of Chrysanthemums for layering in small pots. Petunias and other bedding plants of gross habit should have pruning betimes to keep them within bounds. Root a good stock of Maurandyas, Lophospermums, Ivy-leaved Geraniums, and other climbers that add so much to the beauty of the flower garden. There is no grower who is in the least degree conversant with the cultivation of the Rose but knows that an abundant supply of stimulating materials should be applied to the autumnal-flowering varieties to have these in perfection during the next two months. Without applying manure water in large quantities there will be nothing but disappointment this season. We would, therefore, urge the necessity of stirring the soil about the roots of the Noisette, China, Tea-scented China, Bourbon, and Perpetual varieties, and when this operation is finished give the trees a good soaking with water strongly impregnated with night soil, or with drainings from the dunghill; an abundant, strong, and healthy bloom will be the reward, and the plants themselves will continue for a greater number of years to throw up continually an abundant supply of blooms. Thanks are due to Mr. Mecham for proving on a large scale the advantages which vegetables derive from the application of manure in a liquid form.

From a long experience on a small scale, but with the advantage of a much wider range of subjects, we can confidently affirm that he is right. When once the sewage water of towns can be brought economically to the surrounding lands and market gardens, a great improvement both in the quantity and quality of vegetables will be insured.

GREENHOUSE AND CONSERVATORY.

The time has now arrived when plants intended to afford a floral display under glass during autumn and winter must have attention. Let Begonias have another shift, if not already in pots sufficiently large. Keep the plants thin that their foliage may be preserved from injury. Crowea saligna and Plumbago capensis are both valuable autumn-flowering plants, and the latter furnishes large supplies of cut flowers. Attend to Chrysanthemums, water freely with liquid manure. The earliest winter-flowering Heaths and Epacries must soon be placed under glass, as it will forward their blooming. Where Camellias, Chinese Azaleas and the hybrid Indian Rhododendrons were not potted in the spring, and require shifting, the present will be the most favourable time, as the young wood is now becoming somewhat firm, and the flower-buds are perceptible. As this class of plants require water very liberally during their period of growth, drain the pots well, and use very turf peat and sand, adding an equal portion of fibrous loam for the Camellias. Plants of Brugmansia, whose period of blossoming has passed, may be closely pruned. If drenching rains occur, any tender plants which are likely to suffer damage should be taken in-doors again; there is no occasion to house the whole stock at once. Plants impatient of moisture should not be kept out too long, the solar heat will soon become much diminished and the nights are lengthening, and, of course, evaporation will proceed at a slower pace.

STOVE.

Plenty of moisture to the atmosphere, and plenty of air are still the essentials, increasing the ventilation progressively as the plants approach towards the next period, and inuring them to much more sunlight in a similar ratio, at least those which have made a strong and early growth; shading will, of course, be dispensed with, except in case of bright sunshine during the middle of the day. Pay every attention to such superior stove plants as Allamandas, Dipladenias, Stephanotis, Echites, Euphorbias, Luculia, &c.

FITS AND FRAMES.

Some of the first-struck cuttings will now be fit for potting-off; place them in a pit or frame, shade and keep them close until they are well rooted, when they should be set out to harden previous to being stored for the winter. Continue to put in cuttings, more particularly the best kinds of bedding Pelargoniums, which ought to be struck as soon as possible.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

STILL a burning sun and no water; and we have, therefore, been obliged to suspend all planting operations. Left yellow-haulmed Peas full of produce, that they might shade Cauliflower and other crops. Shaded slightly what little we attempted to plant or sow, and worked a Dutch hoe over the whole surface of the ground, alike to cut up incipient weeds and keep moisture from evaporating. Gave a little water, and only a little, to beds of Endive, Lettuces, Cabbages, Chicory, &c. If this weather continue we expect we must fall back on Chicory and Dandelions for winter salad. We have put down in our memory some outlying corners by the sides of roads where the Dandelion is plentiful, in case it might be needed. With earth like kiln-dried dust, and water driven a long distance for the supply of cattle, it is vain to expect any for the kitchen garden. We fear that pot plants will also have to go to the wall.

FRUIT GARDEN.

General operations much the same as the last. Wasps are now exceedingly troublesome, clearing off netted pieces of Gooseberries, and attacking Peaches, Nectarines, Plums, &c., in the orchard-house. They have come in on us suddenly like a flood, and are much smaller in size than we ever recollect seeing them before. In the spring of this year we never saw so many, so strong, and so wild, the wildness pre-

venting so many of them being caught as would otherwise have been the case. For about ten weeks not a wasp was to be seen, and now we have them in shoals. We have taken multitudes of nests, and mostly at a good distance from us, and many by the sides of highways. In some cases the wasps were stupefied with powder and sulphur before being dug out. In most cases tar was poured into the holes, a little of which stupefied them, and, in many cases, killed all that were in the combs at the time. We have gone to these tarred places, and never found a wasp returning to seek the old nest. When taken in the old way, it is a good plan to sink in the ground a bottle of water, or sour beer, leaving only the hole at the mouth open and level with the ground surface. We have taken bottles half full of wasps by this process. Old wide-mouthed bottles, half filled with enticing liquor, are also good traps, and so is the double hand-light. A common hand-light is set on bricks, with a basin of beer and decayed fruit underneath it. A hole is left in the top of the glass, another hand-light without any holes in it is placed over the first, and the part where they join stuffed with moss, clay, &c. The wasp, after feeding, flies upwards, and roams about until it finds the hole in the lower glass, through which it passes, but never returns again. Some upper glasses already contain many hundreds if not thousands. We have tried poisoning them, but with no great success.

Ants, also, have become annoying on Apricots, &c., out of doors since the dry weather. We cannot settle them as we used to do for want of water to syringe or engine with. A repeated hard engining of an evening with clear lime water would bring almost the whole of them for shelter to the bottom of the wall, and then we used to prevent their reascending by running a band, 2 or 3 inches wide, of tar and oil near the bottom of the wall. The oil prevented the tar from drying. The orchard-houses were almost entirely cleared of ants before the fruit ripened, by strewing some guano on the floor, and chiefly by the side of the wall, and then watering all over with sewage water. The ant hates anything containing ammonia. Clear lime water will often cause them all to sheer off, especially if there is much organic matter in the soil. Though small, they are very destructive in numbers, and should be kept down. They will eat sugar and water with arsenic in it greedily, and soon their existence is settled. We used to place it in little saucers with a bit of wood across, leaving room enough for the ants to enter, then placed another saucer above, and a stone on the top to keep it in its place. When exposed, cats and dogs will be enticed to the mixture. All such poisonous matter should be used with great care. Let us advise all fruit-eaters to beware of what may be in the smallest hole. Unfortunately lives have been lost by swallowing a wasp, and we have known cases where the throat has been much swelled by inadvertently swallowing an ant.

Hexagon netting, and coatings of wool, or cotton wadding will keep out wasps from fruit; but unfortunately all such remedies, by injuring flavour, are deprived of part of their value. For regular houses the best plan is to put gauze over all the ventilators, and then they cannot get in.

For all matters relating to fruit we must refer to previous weeks. We have trouble enough to obtain water to keep Strawberries in pots going on, and for fruit in houses we are obliged to shade more than we like, to lessen evaporation.

We have delayed cleaning the Strawberry rows and quarters, as the runners and old leaves help to shade the ground, and we found the part which we had cleaned and exposed suffered the most from the drought. Apples, though a heavy crop, will, we think, be smaller than usual, owing to the drought. Morello Cherries on north walls, owing to receiving little sun, have been very fine, and the most forward and blackest have been gathered for brandy and bottling, to keep them from the wasps that had begun on them. Melons and Cucumbers we have been obliged to shade more than we like; and pots in the orchard-house, in addition to mulching, we have strewn over with hay and litter, to lessen evaporation.

ORNAMENTAL DEPARTMENT.

Gave a little more air to the small stove, as the moist floor was causing a few of the plants to damp, but we wanted to save watering the individual pots as much as we could, by

giving them an atmosphere in which they were forced to absorb pretty well as much as they perspired. Shaded conservatory with whitening, and kept the floor and stages moist for a similar purpose as in stove, having proved that by such means much less water would be necessary than by giving more air and light and watering each plant as it required it. Shaded all freshly potted plants, as Cinerarias, Primulas, and Geraniums for a similar purpose; and even with plunging will have difficulty in keeping Chrysanthemums growing on healthily. Out of doors it is amazing how well many of the flower-beds look. Calceolarias are yet pretty fair, and Geraniums would be magnificent but for the brown lawn by which they are surrounded. The ground being so dry we fear that a thunderstorm will pretty well dash off the carpet of bloom; but if it does so it will enable us to proceed with our kitchen cropping. What have suffered chiefly are Salviyas and Dahlias, both of which we have been compelled to leave to their fate, as not a drop of water could be given them. It may be trying enough to have a constant dripping atmosphere; but it cannot be so worrying as seeing things dying for drought and no means of averting the ruin.

Our work has chiefly been threefold. First, switching over the lawn with the daisy-knife to cut down any bits of Lotus, Bent, or Plantain, that in various colours raised their heads above the level of the rusty-brown lawn; and, secondly, picking off lots of the exhausted flowers, and moving with a small Dutch hoe every bit of space round the beds, or any little spot among the plants where the hoe could have access, and except at the verge there are but few places where a three-inch hoe could get in. Wherever the surface can be moved it so far acts as a cooling to the plants, and if a shower should come it will go in instead of run away over a hard surface. These little hoes act as hoe and rake; the forward move loosens the surface, or just moves it when loose, and the back stroke makes it as level as any rake would do. For all general purposes in a flower garden as respects the beds, we never allow a rake with its horrid teeth to be used. In all picking, hoeing, &c., we clean as we go, allow no heaps to be formed, to have the pleasure of going afterwards and taking them up, and sweeping and cleaning the bottom of each heap. We recollect in our young days trying how smoothly we could rake a flower-bed, and calling it "dressing" and "high keeping." If the work is taken in time and there is not much to remove, the hoe will leave all in better order as respects encouragement to growth in a fifth part of the time. Then what lots of plants are injured and torn up by the teeth of even a small iron rake! The best plan is to lock rakes up and keep them for some very particular purpose indeed.

The third sort of work has been putting in lots of cuttings after the Verbenas, following with Scarlet Geraniums, &c. These are mostly placed in moveable wooden boxes, at perhaps a trifle more than an inch apart; and though they would do well enough in the open air in ordinary circumstances, yet as we wish to keep up the regular outline of our beds, and therefore select very small bits for cuttings, and besides have little or no water to give them, we place the boxes under shelter of some kind, such as old sashes, tiffany, calico, &c. Thus it is well to suit our operations to our circumstances. The principle of adaptation cannot be too much studied or acted upon.—R. F.

COVENT GARDEN MARKET.—AUGUST 20.

The market continues to be abundantly supplied, both with home-grown and foreign fruit; and vegetables are sufficiently plentiful notwithstanding the drought. Lemons, being scarce, have again advanced in price.

TRADE CATALOGUE RECEIVED.

William Paul, Paul's Nurseries, Waltham Cross.—Select List of Hyacinths, Early Tulips, Gladioli, &c.
Cutbush & Son, Highgate.—Bulb Catalogue for 1864.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

GERANIUMS (*A Subcriber*).—From the state in which the petals were when the blooms arrived the determination of the names was impossible.

APRIS DESTROYING (*N. F. H.*).—The leaves are infested with a kind of aphis, which is very prolific, and equally difficult to destroy, and which does most injury on the under side of the leaf. Smoking the house with tobacco is of little use unless the house be filled with smoke to the floor, for immediately the least smoke is felt they drop on the floor and are then out of harm's way. Tobacco smoke will certainly kill all it touches; but the most effectual remedy is to syringe the plants with quassia water made by boiling 4 ozs. of quassia chips in a gallon of water for ten minutes, and while cooling dissolve in it 4 ozs. of soap. The plants syringed with this, or the leaves and shoots dipped in it, will soon be cleared of the pest. It may be necessary to repeat the operation. Probably the roots are in too rich soil and too deep, and this would cause an imperfect ripening of the wood. We do not feel in a position to express an opinion on the border unless we had details as to its depth and width, and the situation of the roots in it, with the age of the trees. If the trees are young and the border not deeper than 2 feet, we should wait another year and see what effect a season like this will have on maturing the wood.

COLTSFOOT ERADICATING (*Ignoramus*).—If you persist in digging up the roots of every plant as it appears, and never allow a leaf to remain a day without the root belonging to it being dug up, you will find your perseverance will enable you to completely overcome this weed, and a thorough drainage of the land will also assist in doing so. You will find directions for keeping Geraniums, Verbenas, and Calceolarias without heat in Vol. VI., page 447.

WIRE PLANT-STAND FOR WINDOW (*E. D.*).—We fear you have again allowed another error to creep in. Should it not be 3 feet 11 inches long, 1 foot deep, by 1 foot wide? If so, you will have room for two rows of 24 or six-inch pots, and by consulting a wireworker he will suggest many designs without the carpenter being at the trouble and you the expense of his carving one in wood. You may have the bottom of zinc, and have wire-work for the pots to fit into. The wireworker will tell you what will be suitable, and make the stand according to your directions.

FRUIT-HOUSES (*G. W. V.*).—We would call a house for Fig trees a Fig-house, one for Orange trees an orangery; but figery would be equally proper though not customary.

DITTANY OF CRETE (*De Foix*).—Any nurseryman who has a good stock of herbaceous plants could supply it.

ELEPHANT'S FOOT (*An Under-Gardener*).—From your description we have no doubt that your plant is Testudinaria elephantipes, which is known as Elephant's Foot or Hottentot's Bread. It is a deciduous climber attaining a height of 8 feet, and a native of the Cape of Good Hope. The leaves are rearmful and entire; and the rootstock is a large fleshy mass covered with a rough cracked bark, and is used by the Hottentots in times of scarcity as a sort of Yam. It is mentioned in the "Cottage Gardeners' Dictionary" under the head of Testudinaria. The genus Elephantopus is also known as Elephant's Foot. Little David Geranium belongs to the Zonale class.

EVERGREEN SHRUB FOR PORCH (*Yorkshire*).—What reason have your friends for obtaining their Roses from Antwerp, and Pears, Apples, &c., from France? We are quite sure that you will be quite as well served by any of the English nurserymen, taking correct nomenclature and quality into consideration. We know of no evergreen plant better suited for a porch than the evergreen Thorn, Crataegus pyracantha. Crataegus crenulata is, if anything, more handsome, and produces larger fruit in mid-winter. There are red and white berried varieties.

Moss on FLOOR of STOVE (*Toby*).—Sprinkle the floor with sand, after thoroughly wetting it, and then brush it heavily with a brush three-parts worn. Continue to scrub it, adding more sand and water, until the whole is thoroughly clean. It will take some time to clean it. Salt made into a strong brine by the addition of water will kill the moss, but will also kill the roots of everything it comes in contact with, and has the disadvantage of making the floor appear always damp. We know of no safe cure except scrubbing at frequent intervals.

VERBASCUM BLATATA—*CYNOGLOSSUM (T. Theobald)*.—Your plant will doubtless flower next year. Any of the large nurserymen near York could, we imagine, supply you with a plant of the common Hound's Tongue.

TACSONIA MANICATA and BIGNONIA JASMINOIDES NOT BLOOMING (*J. J.*).—We think neither of the plants named have had their wood sufficiently ripened in the preceding summer to allow of their blooming in the succeeding year. Pot them in a compost of turfy loam one-half, leaf mould and sandy peat the other half, with a free admixture of silver sand, providing good drainage to at least one-fourth the depth of the pots. Place the pots as near to the front of the greenhouse as practicable, and train the shoots to wires fixed so as to be about 9 inches from the glass. Keep well supplied with water whilst the plants are growing, but towards autumn gradually diminish the supply, and keep the soil moderately dry during the winter, and the shoots moderately thin. Your plants ought to bloom in the following year. Now is a good time to sow Fern spores.

CUCUMBER-PIT or HOUSE (*An Amateur*).—For the mode of connecting small pipes with large ones, we refer you to the admirable letter of "AN AMATEUR MECHANIC". We have several times recommended the same plan, but the experience of our correspondent is none the less interesting. Had you stated the particulars of your failures with your tank, we might have been able to have helped you. A tank 18 feet long, 2 feet 9 inches wide, and 5 inches deep, formed of wood and covered with slate, ought to have grown first-rate Cucumbers in a low house or pit, if care were taken that the roots were not burned, and also that from the surface of the tank a dry or a moist heat at will could be carried into the atmosphere of the house. If there were no means of top heat except through the soil, then we can easily imagine how the soil might be too hot and the air too cold. We have several times given plans for pits for Cucumber-growing. A very good one on a small scale would be, height at back 8 feet, in front 4 feet, width 7 feet, bed 4 feet in width, path from 2½ feet; two four-inch pipes below the bed, surrounded with clinkers, for bottom heat, two above bed for top heat, plants trained at least 16 inches from glass. In your proposed position you would, of course, form a house, and that would be much better. You do not say what is the height of the gable against which the house is to be placed; but presuming it is 14 or 16 feet in height, we would adopt either of these heights for the back wall; and for 10 feet in width we would make the front wall from 3½ to 4 feet in height. This would give a fine slope either for early Cucumbers or early Vines. Then for Cucumbers we would shut off a pit—say 3½ or 4 feet wide, and 2½ feet in height, the outside wall forming one of the boundaries. Then we would place two four-inch pipes at the bottom for bottom heat, and one in front returning by the back for top heat. The bottom ones we would surround with clinkers, the top one in front to be opposite the ventilators in the wall, roof fixed, and a small hinged ventilator along the top—say a foot wide. Trellis 16 inches from the glass. For early Cucumbers three pipes would be required for top heat. The back of the house could be devoted to many purposes. Such a house with different arrangements would do either for Cucumbers or Grapes, but not well for both at the same time. See an answer about Melons and Grapes.

VINES WITH MELON-PIT (*H. R. D. P.*).—We think we recollect your case and what we said about it; but you should have referred us to page and column, as we have turned up several Numbers, and without finding what we wanted. We will do the very best for every correspondent at the time; but it would be impossible for us to retain individual cases in our memory, and our friends should not give us unnecessary labour. We sometimes receive polite requests as to what volume such and such articles are to be found in, but we decline to do that for our readers which they could so well do for themselves. Now to the questions of our worthy correspondent. 1. You may plant the Vines outside, with the certainty of ripening good Grapes in June if the house is spouted and the border protected with litter and tarpaulin. As stated lately, if put on soon enough—say in the middle of October—dry litter or fern will be better than dung, just because it is safer and easier to keep in the heat of the soil than to send heat into it when it has been cooled. 2. You could grow Melons or Cucumbers in a pit in the centre of the house, and you would do so earlier and better if you had lights to lay over the pit or frame. These lights would enable you to afford a high temperature, or otherwise, to the plants in the bed, when you might be merely starting and breaking your Vines, and when a high temperature for them would be unsuitable. We have grown fine Melons in such positions, especially when the Vines were young. Whilst your Vines were young you might so employ your pit for a year or two with advantage, if you looked after insects. You might continue to do so if you kept your Vines from 4 to 6 feet apart, and were very careful as to insects. If for the sake of abundance of Grapes you pretty well covered the roof with foliage, you would do little good with the Melons under the shade, and they would be more apt to be troubled with insects. In fact, owing to the likelihood of insects, we would give up the use of the pit for anything except a few early things, after the Vines were fully established. 3. You will have abundance of heat from your fire, and therefore for Melons will want no sashes, after the heat of the house ranges from 65° to 70° with fire heat. The size of the flue is very good. For early work you had better have pans on it for evaporating moisture, until your crops approach the ripening state. 4. We think your ventilation will be sufficient, but, to make sure, you had better have a little piece made to open in the end of the house close to the apex.

MUSHROOMS (*An Amateur of Six Months*).—If you send us your address, together with four postage stamps, the Number which you require will be forwarded to you.

BEDDING GERANIUMS (*Stella*).—All the Geraniums named are best, according to what you require. Glendinning's Scarlet is a strong grower and good. Vivid is also good, and between that and Frogmore Scarlet in height. That Frogmore there is no better dwarf free-blooming variety, unless, perhaps, what was a sport from it, the Variegated Brilliant. Trentham Rose, as you remark, is very fine. In this dry weather it is apt to become a little seedy—that is, the trusses will sooner become trusses of seed. Trentham Scarlet is nearly as strong in habit, a good orange scarlet, and, therefore, quite distinct from Trentham Rose, which is a rose. A good neighbour to Trentham Rose would be Rubens, which is a waxy pinkish rose, and endures hot dry weather rather better than the Trentham Rose. Baron Ricasoli is very fair for bedding if not too much exposed. As you sign your name "Stella," we presume you appreciate that variety, of which one of our best gardeners, on looking at a fine line of it, said, "It kills everything else."

SELECT FANCY PELARGONIUMS (*Nottinghamensis*).—Cloth of Silver, Acme, Ellen Beck, Roi de Fantaisies, Lady Craven, Undine.

SELECT VARIEGATED-LEAVED GERANIUMS (*Idem*).—Mrs. Pollock, Flower of Spring, Bijou, Italia Unita, Cloth of Gold, Shottesham Pet.

WISTARIA SINENSIS (*F. A. C.*).—The second flowering of this is by no means unusual in hot dry seasons like the present.

FLOWER-GARDEN PLAN (*A Constant Reader*).—We have no doubt the garden will look well. We presume there are straight lines at the back as well as at the railing, and that may be the reason for having the square figures at the four corners. That, however, is no reason for making these clumps a mere narrow border, round what, we presume, is a square of grass inside. The narrowness of that border will make the planting insignificant in effect compared with the other clumps. Supposing these squares were left as they are, or made into true squares, we would certainly fill up the centre as well by digging the grass down. Then to work in your plants, and make the desirable variety, we would leave 1 as you propose, Tom Thumb 4 5 6 edged with Gnaphalium; 2 and 3, White Verbenas, with a rim of Heliotrope; 5 and 8, Yellow Calceolaria, mixed or centred with Ageratum; 4 and 6, Scarlet Verbena and Purple King; 7 and 9, centre Gazania, and broad band of Lobelia speciosa. Your garden would then be all of a piece, now your 4, 6, 7, 9, will look mean beside the others. There is nothing artistic in the beds, you would see how a small square at Putteridge was laid out and planted, and numbers of other plans have been given. However, your simple plan will look well if well planted.

FORCING PEACHES FOR MARKET (*J. D., Exeter*).—Grow Royal George and Grosse Mignonne Peaches.

BELLE DE DOURÉ PEACH (*W. M.*).—The Peach which you have under the name of Monstrueuse de Doué is doubtless the same as Belle de Doué, which is described in the "Fruit Manual" as follows:—"This is a fine large melting Peach, an early variety of Bellegarde. It is of first-rate quality, with a vinous and richly-flavoured flesh, which separates freely from the stone. Glands round; flowers small. Ripens in the last week of August and beginning of September."

STOCKS FOR GRAFTING VINES (*W. M.*).—We still think the Black Hamburg is the best stock. The Muscat is often much stronger-growing, but it is more tender. It is as well to graft white kinds on whites, and black on blacks, though it does not much signify. In some few cases strange facts have come to our knowledge of stocks influencing scions, and, in the case of Grapes especially, scions influencing stocks—so strange, that without greater corroboration we decline publishing them. We have never seen any bad effects as to setting from grafting on the Muscat.

ALPINE STRAWBERRIES (*F. E.*).—They require the same treatment as to manuring the ground, and general culture, as Strawberries generally. They are best raised from seed, which if sown in a pan in any light earth in March, and placed in a mild bottom heat, will come up in a few days, and should then be removed to a cold frame to harden-off. If due attention be paid to watering, the plants will grow rapidly, and when of sufficient size to transplant they should be planted out in beds, allowing 1 foot between the plants every way. Seed sown in spring usually furnishes plants for late autumn bearing, and the runners of the previous year planted in March or April bear abundantly early in autumn. The ground in which they grow should be well watered in hot dry weather, otherwise they soon cease bearing, and become weak. It must be kept moist in order that they may bear constantly.

SELECT ROSES (*Idem*).—Madame Louise Carique, Souvenir de la Reine d'Angleterre, Triomphe d'Angers, Géant des Batailles, and Madame Trudeaux, are strong-growing free-blooming varieties.

STORING POTATOES (*W. W.*).—It is a good plan to spread them rather thinly in a dry place, or airy shed, for a fortnight or three weeks prior to putting. Greening them by letting them lie on the soil for some days does harm. Your plan will answer, and you may cover them with straw now, with a few spadesful of soil here and there to prevent the straw blowing about, putting on more soil as the frosty season approaches.

PIONEERTIA PULCHERRIMA (*Nottinghamensis*).—It may be kept in a conservatory at 45° in winter when it is blooming, but it cannot be grown in such a house successfully without more heat at the growing season.

GOLDEN FLEECE GERANIUM (*Calcaria*).—If you take up the plants now you will only spoil the appearance of the bed for the remainder of the season. The plants will droop and lose many of their leaves if taken up and potted now; but if you leave them alone until the beginning of October, and then pot them, reducing the heads a little, you will find they will do well in a cool greenhouse, only do not give them too much water.

REMOVING A GREEN GAGE PLUM TREE (*P. Q.*).—If your tree can be taken up with a good root, with plenty of fibres attached, it may be safely removed, but success greatly depends on the care with which the operation is performed. The tree should be removed when the leaves begin to fall in the autumn, and it should fruit the second year after removal, probably the first, but in the latter case it ought not to be allowed to bear much.

NAME OF FRUIT (*T. H. R., Dorset*).—We do not know the Pear you sent. It is a very beautiful and a very delicious one, and we should like to know where you got it from, and any particulars concerning it.

GUANO WATER (*An Amateur Gardener*).—From 1 to 2 ozs. of guano to a gallon of water is quite sufficient.

NAMES OF PLANTS (*F. R. P., Buckley*).—Viburnum lentago. (*C. A. M.*)—Linum grandiflorum var. (*W. S.*, *Hastings*).—Phygelius capensis. (*Maple*).—1, Vicia hirsuta; 2, Trifolium repens; 3, T. medium; 4, Melampyrum pratense. (*D. H.*).—Physanthus albens. (*J. W.*).—Venatrum nigrum: a native of Central and Southern Europe, and Siberia eastward to Japan. You will find a good figure of it in Reichenbach's "Icones Flora Germanicae," vol. x.—J. W. V., must send a flowering specimen of his Justicea. (*E. B.*).—1, Beloperone plumbaginifolia, var. angustifolia; 2, Achimenes pedunculata. (*Geo. Maples*).—Onoclea sensibilis.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

COOKERY AGAIN.

A GOOD friend of ours, who knows we sometimes rush into print, advises us to advertise our capabilities in the way of producing sleep. He says if they were better known some of our papers would be a real blessing to bad sleepers. He describes their effect on himself as most soothing and delightful; a dozen lines make him yawn, twenty-four make him nod, and the entire article produces the calmest sleep he ever has. Some good in them at all events.

It is said "No lady who deals in the finny tribes ever declares those she has are in a state of semi-decomposition," and it therefore stands to reason we like our papers greatly. We are, however, bound to say there are some we like better; for instance, those of a "WILTSHERE RECTOR." We have no doubt he is the head of a happy family. Few things escape him. We liked his paper on "Rooks," but we do not like rook-pie. It may be prejudice, or it may be the foolish idea that they are unclean feeders, but we think it a shame and an insult to good rumpsteak to bake it in such company. We like a chicken pudding; it is a boon in hot weather, and a resource in the summer; it is a valuable adjunct at the luncheon and in moderate families where there is but one dinner *per diem*, and that in the middle of the day. It is a favourite with us. We are compelled to be practical, and have long since tried to find a profitable side to our hobbies. We breed many chickens, and of course some of them are faulty. We shut our ears to all the entreaties to keep this one, because it is so funny; that one, because it eats out of your hand; and another, because it runs all on one side. We shut our ears to the many "attenuating circumstances" the juvenile advocates discover, and when two or three arrive at the size of pheasants we condemn them to the pudding.

Recipe. Let the chickens be fasted and killed. At the end of twenty-four hours cut them up. Do it cleverly. Cut off the wings at the first joint from the body. Take a sharp knife, and, beginning at the end of the breastbone, bring it down in one clean cut to the wing joint on each side; this gives two wings. Take off the merrythought; remove the legs and divide them, giving the thigh and the drumstick. Let the carcase lie sideways on the table, and divide it from end to end, separating the back from the breast; cut the back in half, crossways, and flatten the two pieces; serve the breast the same. Season according to taste. Take some mild bacon, and cut very thin slices. Make a suet crust, put it in a basin, place your joints of chicken and a few slices of bacon in the basin, tie it up in a cloth, and boil slowly for a long time. Turn it out when done. Chickens that are too small to roast and boil are very nice eaten in this way. To those who like the flavour, the addition of a couple of kidneys is an improvement.

Revenons à nos Rooks. We think we recollect a paper among them in the *Spectator*. A good gentleman living in Lincoln's Inn Fields passed much of his time at his window watching them. Observing how frequently they fell to the ground and died, although apparently in perfect health a few minutes before, he was about to read a paper before a learned society, proving that they were very subject to apoplexy, when making the acquaintance of an idle young fellow on the opposite side of the square, he found he was in the habit of shooting them with an air gun.

There is something to be learned from everything that is created. Birds are no exception. A Goose is said to be stupid; but try your best, and you cannot drive over one, though the road may be full of them. All birds are observers. If you have a large cageful, and are accustomed to go into it every day, they will know you, and see you without fear.

If, however, you want to catch one, and have to use a net, you will soon see the effect. From that day, if you go without the net, the birds are careless of your presence. If you take the net, every bird will try to escape you. If you have a smaller cageful of birds, and have occasion to catch some by hand now and then, if there is one spot where you cannot reach them, every bird will crowd there, and nothing will make them leave it.

THE AGRICULTURAL HALL POULTRY SHOW AND THE POULTRY CLUB.

IN replying to your correspondent, Mr. George Manning, I feel thankful that we members of the Poultry Club are not in any way responsible for prize lists, or the getting up of shows, as the Honorary Secretary, Mr. Tudman, very properly informs him; for if this were the case the sooner we take advantage of a recent Act and become a Limited Liability Company, the better. A show undoubtedly can be under the patronage and management of the Club without the Club being answerable for the prize list.

In the course of a week or two, I am told, your correspondent will, on referring to a contemporary, have his curiosity satisfied as to the objects of the Club: but I, for one, object to any non-member being supplied with rules, for which I, with other members, have had to pay. Mr. Manning appears to question the proceedings of the Club. Surely he could afford half a guinea (one year's subscription), and have had all the information he desired, and thereby avoided making what appear to me unjustifiable assertions.—THOS. HUGHES.

ORMSKIRK AND SOUTHPORT AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE eighth annual Show of the above Society took place on the 17th inst., at Southport, on a plot of land in Portland Street, abutting on the Lancashire and Yorkshire Railway. There was a considerable falling off in the number of entries as compared with former years; but, although deficient in number of entries, there was no falling off in the quality of what was exhibited.

DORKINGS.—Prize, J. Blundell, Burscough. *Chickens.*—First and Second, H. Blundell, Southport.

SPANISH.—First and Second, R. Teebay, Fulwood, near Preston.

GAME (Black or Brown-breasted Red).—First, C. W. Brierley, Rhodes, House, Middleton. Second, J. Eaves, Knowsley. *Chickens.*—C. W. Brierley.

GAME (Of any other kind).—First, C. W. Brierley. Second, J. Eaves.

HAMBURGS (Golden-pencilled).—First, C. W. Brierley. Second, T. Ridgway, Burscough.

HAMBURGS (Golden-spangled).—First, C. W. Brierley. Second, T. Ridgway.

HAMBURGS (Silver-spangled).—First, R. Teebay. Second, T. Ridgway.

COCHIN-CHINA (Buff).—First and Second, T. Stretch, Ormskirk. *Chickens.*—First and Second, T. Stretch.

COCHIN-CHINA (Partridge or Grouse).—First, C. W. Brierley. Second and Highly Commended, T. Stretch. *Chickens.*—First and Second, T. Stretch.

GAME BANTAMS (Black or Brown-breasted Reds).—Prize, C. W. Brierley.

GAME BANTAMS (Any other colour).—First, C. W. Brierley. Second, T. Ridgway.

BANTAMS (Any other variety).—Prize, T. Ridgway.

GAME COCK (Any colour).—Prize, C. W. Brierley.

GAME BANTAM COCK.—First, J. Berry, Burscough. Second, C. W. Brierley.

GESE.—First, J. Bryers, Ormskirk. Second, H. Blundell, Southport.

DUCKS (Aylesbury).—First, T. Stretch. Second, J. D. Weaver, Southport.

DUCKS (Any other variety).—Prize, C. W. Brierley.

TURKEYS.—Prize, C. W. Brierley.

JUDGES.—Mr. Joseph Hindson, Barton House, Everton, and Mr. Burnett, Hutton, near Preston.

WAKEFIELD POULTRY SHOW.

THE third annual Exhibition took place at Wakefield on Saturday the 13th instant. Financially, we are glad to say the Show was a great success, the weather being delightfully fine, and, we believe, about 4000 visitors were present. The poultry were not so numerous as we expected; but now that the Hon. Sec., Mr. John Crosland, jun., has means at command, we have no doubt his schedule for next year will assume a better shape, for as poultry is certainly not the least interesting part of the gathering, a fair proportion of the prize money will be allotted to this department. Under

Mr. Crosland the Show was admirably carried out in every respect.

In *Game* the first-prize Black Reds were unusually good, and shown in splendid condition, well deserving the special prize of the silver cup for the best pen in the Show. In the same class a good Brown Red cock was accompanied by a hen minus one claw. *Game chickens* were very good. In *Cochins* Mr. Bishop had both prizes with Buffs such as are seldom seen at a local show. Mr. Lacy's *Brahmas* also deserve notice, and added another to that gentleman's honours. *Dorkings* were good, but out of condition. *Hamburgs* were only moderate. *Game Bantams* were particularly good, Mr. Crosland proving his immense strength in chickens, all of which were first class, and will no doubt be heard of again. In *Ducks* the Rouens were excellent.

The following is the prize list:—

GAME (Black-breasted and other Reds).—First and Cup, J. Crosland. Second, G. Helliwell. *Chickens.*—First, Second, and Highly Commended, J. Crosland.

GAME (Any other variety).—First, G. Helliwell. Second, G. Crosland. *Chickens.*—First, J. Crosland. Second, J. D. Newsome.

SPANISH.—First, R. T. Wood, Clark's Villa Tower, Crumpsall, Manchester. Second, J. Siddall, Rhodes Street, Halifax.

COCHIN.—First and Second, C. T. Bishop, Lenton, near Nottingham. Highly Commended, J. Crosland, jun. *Chickens.*—First, Messrs. Bawn and Briggs, 5, Royal Parade, Harrogate. Second, G. Crosland.

BRAHMA POOTRA.—First, H. Lacy, Hebden Bridge, Yorkshire. Second, C. Lister, Mirfield.

DORKINGS.—Prize, T. E. Kell.

HAMBURGS (Golden-spangled).—First, H. Carter, Uppenthong, Holmfirth. Second, J. Ellis, High Court Lane, Leeds.

HAMBURGS (Silver-spangled).—Prize, J. Crosland.

HAMBURGS (Golden-pencilled).—Prize, J. Crosland.

HAMBURGS (Silver-pencilled).—First, D. Illingworth, Burley, near Otley, Yorkshire. Second, G. Hellwell.

POLANDS.—Prize, H. Carter, Holmfirth.

ANY OTHER BREED NOT BEFORE MENTIONED.—First, C. Lister, Mirfield. Second, J. Ellis.

BANTAMS (Game).—First, Highly Commended, and Commended, Master C. Crosland. Second, J. D. Newsome, Batley.

BANTAMS (Black or White).—Prize, Miss M. A. Crosland.

BANTAMS (Any other variety).—First, W. J. Cope, Barnsley. (Pekin.) Second, J. D. Newsome, Batley. (*Cochin China.*)

DUCKS (Aylesbury).—First and Second, — Hollings.

DUCKS (Rouen).—First, J. Hirst, Bayne Hill. Second, J. D. Newsome, Batley.

Judge of Poultry, Mr. W. Ludlam, Bradford.

MY BLACK BANTAMS.

THE very first paper which I sent to this Journal, now one year and eight months since, was devoted to the description and praise of those pretty pets, Bantams, especially Black Bantams, so, to make a bad pun, "I won my spurs with a charger of sootable colour." Having now further watched the habits of these interesting and useful little creatures, I crave a little more space from you on the same subject. First, I would notice their appearance—Let me describe that trim little cock, now, as I write, crowing on my window-ledge, giving me a saucy and inquisitive look, perhaps for more breadcrumbs, his dear delight, perhaps because I write glancing at him, and he therefore connects himself in some way or other, I know not bird process of reasoning, with me and my present vocation. How brilliantly red is his comb, especially when he is angry, that well-shaped comb, reaching far back in a peak; then his sparkling eye, and white ear-lobes, contrasting so well with his bright jet-black plumage. Then, again, what a beautiful hackle he has (I like much hackle in all cocks), it flows down his neck, over his shoulders it falls—so pointed and black is each feather, I compare it to nothing less than the "back hair" of some Spanish belle. Scarce less noticeable is his short curved strong beak, such a weapon of attack; then to complete him his silky-falling saddle, and his arched and flowing tail, and his whole body, especially his wings, glistening with metallic hues. Nor is the little fellow's figure, nicely poised upon his firm legs, less noteworthy, or that broad full breast, with head carried defiantly. Whether the poet Dryden ever kept Black Bantams I know not, but at any rate his description of the cock in one of his fables might lead one to suppose he did.

" High was his comb, and coral-red withal,
In dents embattled like a castle wall;
His bill was raven-black, and shone like jet;
Blue were his legs, and orient were his feet;
White were his nails, like silver to behold;
His body glittered like the burnish'd gold."

Take him all in all I am inclined to think that a well-bred Black Bantam cock is among the very handsomest of our domestic poultry. He is, too, a very clean little fellow. It is our custom to breakfast daily in the study, but on Sundays we take that meal in the dining-room. I had, a few years since, a cock of this breed who came regularly to the window at eight o'clock, tapped with his beak (if not noticed he would go on tapping, letting us have no rest), and have his breakfast of crumbs. But when Sunday morning came, he would first make his appearance at his regular window, but, alas, no welcome tablecloth, with good things on it, was to be seen; he would then run round the corner of the house at full speed, with his head on one side, listening for the sound of voices, passing front door and drawing-room windows, and at the dining-room windows he appeared for certain, crowing, tapping, and confident that his appeal would be successful. This bird was the cleverest fowl I ever had—but, in passing, let me say, the more you pet poultry, the more of mind or sagacity do they reveal, but gradually cease to pet and caress, they return to mere fowls of ordinary type. This bird used to fly up to my children's heads or shoulders, stand on my foot and crow, and yet he was never vicious, the youngest bare-legged little child was no sufferer from his familiarity.

Next let me notice the precocity of the Black Bantam. I have now by me four chickens of this breed, hatched on the 10th of last May, also four Game chickens, Black-breasted Reds, I do not mean Game Bantams, these were hatched on the same day, consequently they are all just three months old, for I write on the 10th of August. Now the Game cockerel is only a long-legged gawky boy, with almost colourless comb and wattles, he has never attempted to crow, while the two black cockerels have crowed these six weeks, and now execute that adult accomplishment to perfection. They also walk with the hens, one is particularly fond of an old hen, and as I sent away my late cock, the master of the two cockerels is in all respects the Sultan.

I wish somebody could supply me with the pedigree of Black Bantams, for I find them more game than Game. For instance, my Game chickens are of a prize strain, willow-legged and all the rest of it, but the black cockerel not only drives off the Game pullets, but is totally master of the Game cockerel, leading him a wretched life, for, not content with giving him a peck and done with it, the little tyrant hangs on his wing, and punishes the poor long-legged boy terribly, he never daring to turn again. Of course there will be a day of fearful retribution presently, a turning the tables, a Nemesis, and my only fear is that the grand battle will end fatally, in case of no eye seeing the fight, for my brave little fellow will fight to the last, of that I am quite confident.

I know no one possessed of Black Game fowls, but I should like to try a cross between the two black kinds, Game and Bantam. A very nice little fowl would, I should think, be the result, and a profitable one too (and why not make pets profitable?), for the black pullets are excellent winter layers. I want to breed a fowl, laying well, and also a fair size. I should know I was eating a Black Bantam egg if I had my eyes shut, and then next in my estimation comes the Game fowl's egg. Now a cross would bring a bird with good points and properties, fit too for open gardens like mine; and every one should keep half a dozen little fowls, even if they have no separate yard. Can anybody help me in this matter? Good laying, good-looking, spirited little fowls, too small to scratch up a gooseberry bush, or even a scarlet geranium, would, I think, be welcome to many.

I have said nothing about the little black hens. Certainly I do not find them equal to the cocks in intelligence, but they are neat-looking birds, some of them good sitters, all excellent mothers. The pullets have charming little heads as they peer at one from a bed of potatoes. I also find that the colour of the hens, originally of a dull black almost brown, improves when you avoid breeding in-and-in.—WILTSHIRE RECTOR.

PIGEONS' FOOD.

I HAVE kept Pigeons many years, ever since I could hold one, and having had some experience of the different kinds of grain as Pigeon's food, I should be glad to exchange

notes with other fanciers as to their opinions respecting the quality of various sorts of corn as food for Pigeons under different circumstances.

I have generally been in the habit of allowing my Pigeons to fly out for the greater part of the day, and under such arrangements I find most kinds of food are wholesome, and the Pigeons thrive well when they can provide themselves with lime, gravel, and green meat. They always had access to a bath in fine weather, and also to salt. Disease was then almost unknown among them. Now things are much altered, not altogether for the better. I am living on the top of a hill in a bleak situation; our water is from a well, very soft, and contains no lime. My Pigeons are high bred and tender, being Tumblers of different sorts—as Scotch, House, and Air Tumblers; Rollers; High-flying Tumblers, and Short-faced.

The House Tumblers and many of the Air Tumblers cannot fly, from their tumbling so much, while some of the Rollers if put on the wing will roll till they strike the earth, and would in consequence injure if not kill themselves, and for this reason my Pigeons do not have their liberty, except the High-flying birds and the young ones, which are let out once a-day when weather suits. They fly for about two hours and then go in.

It will thus be perceived that under present arrangements a delicate breed in a bleak place, highly fed, and taking no exercise, must be liable to complaints unknown to a hardier race in a more natural and genial condition. I am in hopes of obtaining a better and more sheltered place, and so avoiding some of the difficulties. Still some persons may say, Why not keep a breed that can take care of themselves and so be let out? but every one to his own taste. I flatter myself I have a first-rate breed of Tumbling Pigeons and do not desire to change. I have now explained under what circumstances I have noticed the effects of various sorts of food.

TARES are generally considered the best food for Pigeons. I must agree with Mr. Eaton when he says they are relaxing, and too much purging is not conducive to health.

BEANS.—Small old beans are by many declared to be the best of all food. I find them strong and warm, if I may so express myself. I cannot well succeed without them, yet I regard them as heating; the old Pigeons will breed too fast on them, the cocks drive to nest so determinedly that they neglect the previous hatch; and, moreover, beans do not readily make soft meat, and the transition from soft meat to beans is too sudden for delicate young Pigeons already weakened by neglect, consequently, many die.

PEAS are very nutritious food, much recommended for Pigeons to fly on; but I find if my Pigeons have many peas the hens lay soft eggs.

LENTILS.—I have not tried any of this food of late years, but when in Germany found it good, and it is highly nutritious.

VETCHES.—In France I fed my Pigeons principally on small grey vetches and liked them very much as food; but that is some years since, and I cannot compare them with present food.

WHEAT.—Very fattening and excellent for feeding young Pigeons on; but the old ones become fat, lazy, and soft-feathered on wheat.

BARLEY.—Very well as a mixture with peas, but I do not regard it as a good food, and the Pigeons do not seem to relish it.

BUCKWHEAT.—A very good addition, the Pigeons are fond of it, and I regard it as beneficial, but have not tried it much.

HEMPSEED.—Very fattening and exciting, and not good as a constant food; but useful in getting birds into condition or hastening pairing or breeding.

CANARYSEED.—I have a high opinion of this, but it is too expensive.

RICE bears a bad name, but I find it useful as a mixture to prevent diarrhoea, and think the Flying Tumblers fly better since they have had a little.

I should be pleased if any other fancier would compare notes and give me the benefit of their experience, either through the columns of this Journal or privately. It will be advisable to name the breed of Pigeons, whether in confinement or at liberty, how they are fed, and, what I regard as

of great consequence, the quality of the water they drink; for I think this is of much importance to a bird that drinks so copiously as the Pigeon, the water often containing various earths and salts according to the nature of the soil from which it is obtained. The subject of food, I think, is one well worth the trouble of a little investigation, and I shall be pleased to hear the opinions of others.—BERNARD P. BRENT, Dallington, near Robertsbridge, Sussex.

PIGEONS AT NEWCASTLE-UPON-TYNE AND DARLINGTON SHOWS.

A LETTER in your last Number, page 139, signed "A FANCIER," I cannot allow to pass without giving some explanation. I regret exceedingly that there should be any ground for complaint as to the judging of Pigeons at the Newcastle Show, as I had, perhaps, more to do with selecting the Judges than any one else.

When the Newcastle Show was first decided upon, Mr. Hewitt was fixed on as Judge, knowing that this gentleman's decisions almost invariably give satisfaction. He was written to, and accepted the office; but a few days previous to the Show taking place I received a letter from Mr. Hewitt, stating that he thought he could not comfortably get through the number of entries by himself in the time allotted, and suggested some one at least should be secured to take the Pigeons off his hands. I was, consequently, tied for time to obtain a Judge for this department; but happening to place my hands upon the Darlington catalogue for last year, I noticed Mr. Botcherby acted as Judge there, so I concluded at once that if Mr. Botcherby was competent to judge at an important Show like that at Darlington, I could not be wrong in asking that gentleman to do so here, and I wrote to him immediately, and procured his sanction, consequently the matter was decided. Previous to this I had not heard a single word about the dissatisfaction his judging had given at Darlington, or you may depend upon it I should have avoided the services of Mr. Botcherby. However, I believe Mr. Botcherby to be highly respectable and honest as a judge, but as to his competency for such a task I confess I know but little.

You must also permit me to rectify an error in the letter referred to. I did not reverse a single card that Mr. Botcherby had placed upon the Pigeon classes; but unfortunately some of Mr. Yardley's birds had remained in the basket until after the awards were made: regretting this as I did, I proposed to Mr. Yardley that if the amount of a first prize would satisfy him for the oversight in not putting the birds in their proper place in time, I should be most happy to pay over the extra amount, which Mr. Yardley accepted.—J. SHORTHOSE.

ON looking over your last Number, I find a letter from "A FANCIER" criticising the judging of the Pigeons at the Newcastle and Darlington Shows. His strictures upon the former may be all very right, I am not in a position to give an opinion; but some of his remarks upon the latter are quite beside the mark.

In the first place, he gives his readers to understand that Mr. Botcherby was the only judge at Darlington; but on referring to the catalogue, which I happen to have, I find, under the Pigeon Judges, the names J. W. Botcherby, Esq., F. Bellamy, Esq. "FANCIER" altogether ignores the fact of the latter gentleman's having officiated. Now, I know nothing whatever about Mr. Botcherby's capabilities; but I think every fancier will admit at once that Mr. Bellamy is a thoroughly competent judge, and, taking his presence at Darlington into consideration, I cannot think the awards were so outrageously bad as "A FANCIER" would have us believe.

Again: he says, "The silver cup for the best pen in the Show was awarded to an old Dun cock, a draft from the loft of one of our well-known exhibitors; while one of the best Carriers in the kingdom and in her prime, a black hen belonging to Mr. Else, of London, was shown." Now, I am prepared to prove that the Dun cock spoken of was, when exhibited at Darlington, under three years old, and, to use "A FANCIER'S" own words, in his prime, and one of the best Carriers in the kingdom.

With these misstatements before me I cannot help thinking that if inquired into some other of "A FANCIER'S" "facts incontrovertible" might prove fictions. To my thinking there is a feeling of soreness throughout his letter which reminds one very forcibly of "sour grapes."—J. I. D.

"A DEVONSHIRE BEE-KEEPER" VERSUS THE "TIMES" BEE-MASTER.

FOR the credit of British journalism, I regret to state that my second letter in reply to the acrimonious tirade of the "Bee-keeper" in the employ of the *Times*, who turns out to be Dr. Cumming, the well-known controversialist, has been refused insertion in that paper, although another violent attack on me from the learned (?) doctor's pen appeared in the *Times* of the 12th inst. Of this precious production I need only remark that it is worthy of its predecessor, and that it fulfils a prediction made by the *Aberdeen Free Press* of the 5th inst.—viz., that the doctor was using his influence with the view of puffing a book which he intends publishing. Unlike Dr. Cumming's own interpretations of prophecy, this prediction has been literally fulfilled by the astonishing announcement that a man, who cannot write a letter on the subject of bees without blundering in every paragraph, is not only about to "put together" a book upon them, but has actually found a publisher willing to run the risk of printing it! Although the publishers of cheap literature have been notoriously unfortunate in their selection of apian writers, and the compilations of Messrs. Richardson and Wood must therefore be deemed formidable competitors in the race for pre-eminence in ill, Messrs. Low may safely be congratulated on having secured the copyright of what will in all probability turn out to be the most inaccurate bee-book ever manufactured.—A DEVONSHIRE BEE-KEEPER.

ILL-SUCCESS IN BEE-KEEPING.

THE letters in the *Times* about bees have somewhat revived my interest in my own, which for several years I have resigned to the care of the gardener, an old-fashioned man, whose only ideas on the subject are tinkling and burning. For the last three years I have had neither swarm nor honey, and my six or eight hives have diminished to two, the reason being, as the gardener insists, that I gave away my luck by giving a swarm to a friend!

Now, I wish to try if I cannot bring back my luck by taking them in hand myself; and I venture to ask if you will be kind enough to tell me what is the simplest and best kind of hive? I had been thinking of obtaining one of the nadr-hives, recommended in the Rev. W. Law's letter in the *Times*; but it occurred to me before I saw by Mr. Woodbury's letter that the principle was contrary to the nature of the bee, and therefore I am hesitating what to do. Can you also kindly advise me what to do under the present state of affairs?

Two or three days ago, on opening the bee-house, which I had not looked into before this year, I found that the bees (in two common straw hives with flat tops), had made an immense quantity of comb outside the hives, thus connecting them together and with the roof of the house, which is now nearly filled with honey, and covered with clusters of bees. The two hives stand on a shelf. The gardener says the only thing to be done, is, later in the season, to burn the bees and take the honey; but I am most anxious to save the life of my poor bees, and should feel very much obliged if you could put me in the way of doing so, and also of going on better for the future.

Some years ago I tried putting a glass over the hole in the centre of the hive; but though the bees on one occasion made a small piece of comb in it, they did not fill it, and I have never succeeded in obtaining honey in that way.—C. S. B.

[You cannot do better than use flat-topped straw hives, with a three-inch hole in the top. You require the assistance of a practical apriarian, who, by the aid of a little smoke, would soon cut away the extraneous combs, and compel the bees to retire to their hives. Had you supered your stocks this season, you would doubtless have obtained a large

quantity of honey. Glasses require to be kept warm by an external covering of flannel, or some other non-conducting material; and the absence of this precaution, and the possible want of decoy-comb in the glasses, are the most probable causes of failure.]

BEES FORSAKING A STOCK-HIVE.

EXCEPTING myself, no one in this neighbourhood, so far as I am aware, keeps bees, and the present is only the second season of my doing so, and this must be my apology for asking for information.

In May last year, I bought what was considered, and I believe, was a good top swarm, which threw off another after I had had it about a month. I kept them through the winter, both being strong and healthy. This season the parent hive threw off two swarms, the first in the end of May, and the second about three weeks later, both of which continue, so far as I can judge, healthy and active. About a month ago I remarked that the occupants of the original hive seemed to become lazy, not showing themselves outside in numbers like those of the five neighbouring hives, and such as I should have expected from their supposed strength. Daily their numbers seemed to diminish, till within a few days past there has been "no appearance," and no sound of life from within. I lifted the hive off the board; and not a little, I confess, to my disappointment and surprise, found that they had fled, leaving about $1\frac{1}{2}$ lb. of wax, but not an atom of honey. Now, will you kindly inform me how this is to be accounted for, and in what way I can prevent similar casualties among my bee stock in future?—E. J. S.

[The bees have, doubtless, vanished from the old stock owing to the absence of a queen, and this may have arisen from various causes after the departure of the last swarm. The remaining bees may have failed to raise a queen. Your stocks may be placed too close together, and the young queen may, therefore, have perished through mistaking her hive on her return from her wedding flight, or she may have been "worried to death" by her own subjects, as related by "A DEVONSHIRE BEE-KEEPER," in page 80. All that you can do in order to render such a misfortune less likely in future, is to take care that your hives are a sufficient distance apart.]

DEPRIVING.

I HAVE adopted the Woodbury bar-hive and super as recommended in the manual of "Bee-keeping for the Many." I find that the stock-hive contains from 45 to 50 lbs. of honey, and the super is filled with comb, but there is scarcely any honey. The space also between the bars of the stock-box and adapting-board is filled with comb and honey so full that it appears one solid mass. Now, I am anxious to take about 25 lbs. of honey from the super and stock-box, so as to leave 25 lbs. in the stock-box to supply the bees during winter. What plan would you recommend me to adopt?

I should remark that I had to remove the adapting-board upon three or four occasions when I first put on the super as the bees would not take to the super at first, but would work between the top bars of the stock-box and the adapting-board. My adapting-board has openings near the sides about a quarter of an inch in width.

As I have discovered a sure system of ventilation, I think of having hives made of glass sides covered with board shutters lined with flannel, so as to be able to expose all four sides to view at once. In order to take the honey from my present box, do you think I should succeed if I were to remove the cover of the super and place on it a hive containing 25 lbs. of honey, and to drive the bees into it by tapping at the sides of the stock-box and super? Perhaps, however, a quarter of an inch would not be sufficient space for the queen and larger bees to ascend. In that case I should have to enlarge the opening in one part. I have an empty box with frame-bars.—J. H. L.

[If the bees can spare them there is no objection to your appropriating the two side combs only from the side box. Their places will be best left vacant during winter, and in spring they may be advantageously filled up by a couple of

empty combs from the super. The combs remaining in the latter should be taken care of, as they will give the bees an excellent start in filling the super next spring. Bees generally fill the vacant space between the bars and crown-board with comb which may be scraped off when convenient, but you need not have removed the crown-board purposely.

You had better allow your bees to remain in their present domicile, and stock your new hive with a swarm in the spring.]

AUTUMNAL UNIONS.

I HAVE bees in a common cottage hive, and I wish to take the honey without destroying them. I am told I can fumigate them with the puff ball. I tried doing so but lost my bees. I was afterwards told I could effect my object by using chloroform: this I also tried, but whether the chloroform was good or bad I cannot say. I failed again. Some people think it a good plan to drum the bees; but I should fear to rely on it. If you do not object to kindly advise me what plan you consider best to deprive them, without destroying them at this season of the year, I shall esteem it a very great favour.—J. H.

[Chloroform is destruction to bees, and fumigation we believe little better. The best mode of appropriating the contents of common cottage hives in autumn is to drive the bees and unite them to other stocks. Articles from the pen of "A DEVONSHIRE BEE-KEEPER," describing the best way of performing these operations, appeared in Nos 139 and 144 of our new series.]

REMOVING AND TRANSFERRING BEES.

I WISH to ask one or two questions respecting bees, if you will kindly answer them.

1st. I find I must shift my apiary as follows:—One lot some 20 feet to the right, but exactly in the same line as before, and another lot some 40 feet in front, to shift them by the side of the first lot. Will you kindly inform me whether it is practicable so to do, and the best time?

2nd. I have taken 30 lbs. good from each of my eight hives, on the depriving system. Would you advise me to take any from the stock-box?

3rd. What is your opinion as to transferring bees at this season into an empty hive—say from a straw to a bar-hive?

4th. Which do you prefer, the collateral or storifying system?—JOHN NEWLAND.

[The best plan will be to remove your bees temporarily to a distance of not less than a mile and a half. This may be done at once, and in three weeks' time they may be brought back and arranged in their new positions.

We should say, as a general rule, do not plunder stock-boxes.

Bees with their combs may even now be transferred from straw into frame-hives, but it requires a considerable amount of aparian skill to perform this operation successfully.

We prefer the storifying to the collateral system.]

A GOOD BEE-HIVE.

SEVERAL correspondents have written to us inquiring what is the best style of bee-hive, where it can be obtained, and how it is managed. We have been at some pains to collect information on these points; and we shall now give the results of our investigations, in the hope that they may be of service to intending or actual bee-keepers. We present herewith two illustrations of a hive, which, without hazarding the assertion that it is absolutely the best in existence, we have no hesitation in pronouncing a very good one, and, on the whole, the best that has come under our observation. It is manufactured by Mr. P. A. Scott, an ingenious mechanic of Toronto. This hive bears a strong resemblance in its leading features to the Langstroth-hive, but embodies improvements suggested by other eminent apiculturists, as well as some peculiarities of Mr. Scott's own devising. A very fair general idea of its outward appearance and internal arrangements may be gathered

from the accompanying cuts, but a few explanatory remarks may not be wholly useless.

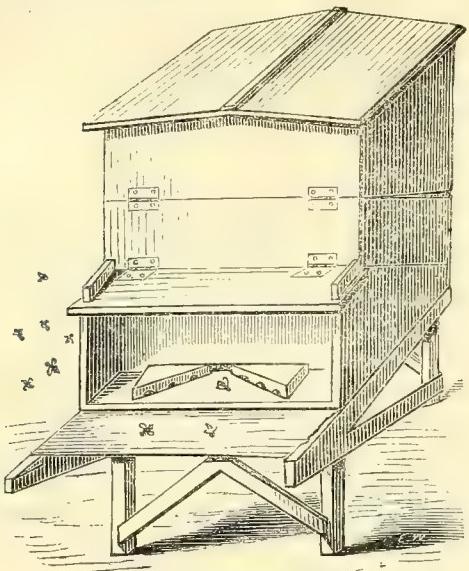

Fig. 1.

The above engraving (fig. 1), shows the hive in its usual closed state, and it will be seen that it has an independent stand, and is well contrived for protection against the weather. There is no danger of its being blown over, and it

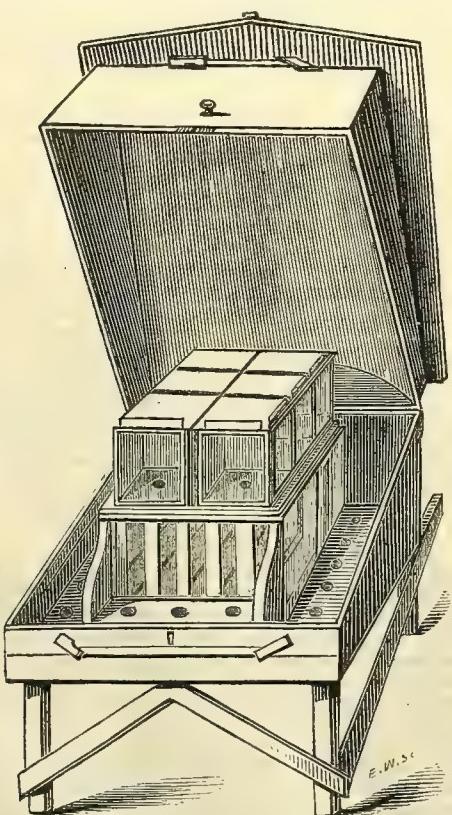

Fig. 2.

is furnished with lock and key so as to be safe from unnecessary disturbance. It is made to slant towards the entrance, to facilitate the carrying out of dead bees and other useless

substances. Traps for the bee-moth are made in the moveable blocks at the entrance of the hive. A strip of cloth is tacked across the front, so that the bees when they come home heavy and clumsy with their load of honey may not be bruised and injured by striking against a hard board. Ventilation is provided for on the outside of the hive, and it can be regulated without disturbing the occupants. The ventilators are covered with wire cloth, so as to exclude the enemies of the bees. Dampness is carefully guarded against. The exterior of the hive is painted to preserve it from the weather and give it a neat appearance.

The second cut (fig. 2), exhibits the interior of the hive, which is so constructed as to give the bee-keeper entire control over the combs without injury to a single bee. It may be well to observe that the accompanying illustrations present two different sizes of the hive. Three sizes are made—those represented are the medium and largest sizes. The closed hive, as will be seen by the two sets of hinges, is double-storied. The open hive is one-storied. The lower part of the open hive, which may be considered the main portion of this bee-dwelling, is fitted up with moveable comb-frames, while above there is a set of boxes into which the bees can be admitted at pleasure. The moveable-comb principle may now be considered as fully established. All intelligent and experienced bee-keepers regard it as a most valuable addition to the facilities for managing bees. The frames shown in the cut are so made as to guide the honeycomb in a straight line, and any one of them can be taken out and examined without disturbing the rest. They save labour to the bees, and give the bee-keeper full management of the internal activities of his insect family. The comb may be removed from the frames without cutting, and, if desired, the honey can be taken from the comb, and it returned to the hive to be refilled, or good pieces of worker comb may be put in the spare honey-boxes. The condition of the bees can be inspected at all times with perfect ease, the chambers being enclosed and partitioned with glass. This hive is adapted either for a strong or a weak colony. It can be either swarming or non-swarming, as may be preferred. Two swarms can be united in one hive, if it be desired. Artificial swarming can be readily accomplished in them, and the uncertainty of natural swarming may be entirely obviated.—(Canada Farmer.)

OUR LETTER BOX.

NANKIN BANTAMS (*Constant Reader*).—We cannot tell you where to obtain the Bantams. We have seen none for a long time.

SULTAN FOWLS (*Ignoramus*).—We fear we cannot help you. Miss Watts was the importer of these beautiful birds. We fear the breed has not been kept pure.

DUCKWING GAME FOWLS (*Amateur*).—We do not know the Red-breasted Duckwinged Game, nor have we heard of any. We are not more enlightened with regard to the machine you speak of, we have neither seen nor heard of it.

PIGEON UNABLE TO STAND (*W. K.*).—Your White Dragoon has probably ruptured a small blood vessel on the brain; rest and quiet will be best for the bird; and time may effect a cure by absorption of the suffused blood.

HIVES (*F. S., Derby*).—Flat-topped straw-hives, with a three-inch hole in the top, are as good as any for ordinary bee-keeping and working supers. The Woodbury frame-hive is the best for scientific and experimental purposes.

GOLD FISH (*F. G. S.*).—If there are plants growing in your basin for the gold fish to spawn on, and the water is not too cold from the fountain, the fry will be hatched readily enough; the only fear will be of the old ones eating them up. Perhaps the old fish after the spawn is deposited might be removed.

GOLDFINCH WITH ELONGATED BEAK (*E. G. H.*).—You can pare the beak of your Goldfinch with a penknife, or pair of sharp scissors, back to its proper length, without any injury to the bird.

LONDON MARKETS.—AUGUST 22.

POULTRY.

We should have nothing to note were it not for the advent of Grouse. This year seems desirous to make amends for past shortcomings. There have seldom been so many in the market the first week as this year. The quality is excellent.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 70.7°, and its night temperature 47.4°. The greatest heat was 85° on the 1st, 1843; and the lowest cold, 33°, on the 3rd, 1862. The greatest fall of rain was 1.50 inch.

QUALIFICATIONS OF THE SCARLET GERANIUM FOR BEDDING.

HEEN in bygone years such florists' flowers as Tulips, Auriculas, Ranunculus, Polyanthus, and Pinks held a higher place in public estimation than they now do, many villages of no great pretensions had their periodical shows, which were looked forward to with considerable interest by aspiring exhibitors. Each class of plants had then to be judged by a code of

rules which, unlike the laws of the Medes and Persians, were altered if found defective. Whatever opposition may have been offered to these rules at times, and whatever changes were made, it is certain that the flowers which stood high in public favour in the beginning of the present century were judged according to the closeness with which they approximated to a certain standard of perfection which was supposed to be equitable. The rules which then existed are far from being obsolete at the present day, although, instead of a universal adherence to them, a sort of anarchy has sprung up, every man making laws for himself, so that even in such important flowers as the Azalea, Rhododendron, Scarlet Geranium, and many others, the points of excellence are far from being universally defined. Flowers have never been so popular as they are at the present day, but there is in many instances a lack of knowledge of the properties which fit a plant or flower for a certain purpose, and it would be a most desirable result if florists would determine on some standard that is not absolutely unattainable, and judge the respective merits of each claimant for distinction by the near or distant approach it makes to that standard. I therefore invite everyone to put forth his own views as to what constitutes perfection in one of the most useful as well as most popular of all our bedding plants—the Geranium of the Zonale section.

In calling attention to this subject I confess having some misgivings as to a universal acknowledgment of any particular set of rules being attained, but, at the same time, much useful information may be obtained, and matters which individual growers might set down as established rules might be modified or set aside entirely by the majority; so much, indeed, depends on the character of the season, the soil, and other features, that the decided opinion of one individual might in a large assembly of growers receive very few or perhaps no backers. Take, for instance, the present season up to the 20th of August; in this district it has been a very dry one since the Geranium started into growth, and as one of the effects of the dry weather we see a greater abundance of bloom on Geraniums than we were wont to do, and a diminished growth. Sturdy, rank-growing varieties have

descended into the condition of medium growth, those of dwarf habit have been still more diminutive, and the whole have been alike loaded with bloom to an extent not generally met with. Judging them by the present season only we are struck with the idea that the strong and vigorous kinds are the best; but this is solely owing to the absence of moisture in the air and ground, and the consequent tendency of the plant to expend its energies in the formation of flowers and seed. If dry weather were to continue, and the plants were not supplied with water artificially, there would be every likelihood of their flowering themselves out, as the saying is—a circumstance of rare occurrence with the Geranium, though by no means so with many other plants. Indeed, I think there are examples already amongst our bedding Geraniums indicating a cessation of blooming at no distant date, unless rain or artificial means push them into fresh growth; but even in the latter case the bloom will be late and far from abundant.

Before entering on the qualities necessary to constitute a first-class bedding Geranium, I must allow that my experience of some kinds this year is diametrically opposite to what it was last season, as some varieties I had then almost made up my mind to discard, have this season been the best I had, and others the reverse: therefore we ought not too hastily to condemn anything without a fair trial. The present year having proved that strong growers are the best, are we justified in depending on them entirely for another season? To this I unhesitatingly answer, No; for until we have the character of the forthcoming season placed before us we must continue to provide against the contingencies which each succeeding year brings with it. If next year be damp, and we have only coarse strong-growing Geraniums to depend on, we shall have little bloom, and the beds will be overgrown with rank foliage.

Let us now see what really constitutes a good bedding Geranium, leaving those extremes of wet or dry seasons out of the question, as they may be discussed hereafter. Although I by no means assert that the standard I lay down is the one that may be generally approved of, still it may serve as a basis on which to found a more complete and perfect system; premising, therefore, that the plant is wanted for bedding purposes, and confining my remarks to the Scarlet-flowered section, which is, perhaps, the most extensively-planted of any, I would define the desirable properties thus:—

Habit.—Strong but not coarse; spreading rather than upright; joints short.

Foliage.—As deep and shining a green as can be had, with the least possible horseshoe marking upon it; leaf-stalk short but strong, the leaf itself somewhat convex, and its edges smooth.

Flower.—Truss medium sized (not but that large trusses are better than small, but they are also fewer in number), each individual bloom to conform to the standard that is generally laid down for a good flower. The truss ought to be compact but not confined, and the bloom the same in colour to the centre, a white eye being objectionable. The

less the plant is given to perfecting seed the better; and kinds having seed-vessels pointing downwards instead of upwards are the least unsightly. The flower-stem to point upwards generally, although this qualification on the outside plants is rather a disadvantage. The stem may either be green or white, but I cannot see any advantage in the latter colour.

By the above rough outline it will be seen that I have preferred the plain Green-leaved class to those marked with the horseshoe. The latter I have no objection to admit as pot plants for more close inspection; but at the distance most flower-beds are viewed at, the black marking is rather a defect than otherwise. For a like reason I have condemned the white eye, and have preferred the spreading in habit to the upright grower. For particular purposes, perhaps, a variety of upright growth might be preferable; but for general use one that spreads laterally, with at the same time sufficient sturdiness to support itself, is better. A very long flower-stem is no particular advantage so far as I can perceive, but the flower ought to be well elevated above the foliage, say 3 inches or so above the highest part of any leaf; and as the stalk must descend some distance, there will be plenty for all nosegays or flower-stands. I might also have added that flowers that will withstand the greatest amount of sun, wind, and rain are preferable to those less serviceable; and if they drop off in decaying they are better than if adhering to the flower-stalk, as attention to picking off the blooms is not possible everywhere, and in such cases the varieties which do for themselves are better than those that have to be waited upon.

The above remarks having extended to a greater length than I intended, I will at a future time enter into the merits of the Variegated class, which, I may observe, is every day becoming more and more numerous. In the meantime I invite opinions on the merits of the Scarlet class; and later in the season I will report on the kinds which we grow here, for it would be premature to do so in the middle of the season. I may, however, confess that one or two of my greatest favourites last year have signally failed this season, and I have no doubt it has been the same elsewhere. Other changes, too, may take place ere the flowering season of 1864 be at an end. As the Geranium is unquestionably at the present moment our most popular bedding plant, anything bearing on its merits as well as on its management must be acceptable to the general reader; and as my worthy fellow-labourers in this Journal have at various times set forth its culture, it remains only for us to determine what constitutes the right sort of plant to cultivate. I hope, in conclusion, that everyone opposed to the views above stated will at once put his own on record in the pages of THE JOURNAL OF HORTICULTURE.

J. ROBSON.

BEDDING GERANIUMS.

(Continued from page 86.)

ALTHOUGH it is advisable to put in the stock of bedding Geraniums in August, propagation is sometimes deferred till September, which is not nearly so good a time, as the cuttings are then more gross and watery, and on that account more liable to damp off; the sun's power is also less at that season, and the cuttings have to be struck under glass, a little heat being necessary to cause some of the variegated sorts to root freely. These late-struck plants, too, are later in making a show in the following season, and with Golden Chain and other slow-growing and rather delicate kinds, the practice does not accomplish the object aimed at—viz., providing strong plants to decorate the flower garden in the following season. Where the propagation of Geraniums has been delayed until the last week in August or beginning of September, cuttings should be taken at once, and inserted singly in small pots in a compost of light turf-loam with a liberal admixture of river sand. Silver sand is preferable for some of the variegated kinds, for they do not grow so freely as the Scarlets. These cuttings, if placed in a viney, or any house with not too dry an atmosphere, if shaded a little and the soil in the pots kept sufficiently moist, but on no consideration wet, will root freely in three weeks or a month, and may then be removed to a light airy situation in the greenhouse, where they will only require water to prevent

their flagging and losing their leaves. All yellow and decayed leaves should be removed as they present themselves.

Another method is to insert four cuttings in a 32-sized pot, six in a 24, or eight in an 18-sized pot, placing them round the inside, and if they are kept in any house where there is a little heat and a not-over-plentiful circulation of air, they will become well rooted before the dull dark days of winter set in. The pots are then placed near the glass in any light airy structure from which frost is excluded. A readier mode, and one that takes up much less room, is to employ propagating-pans 1 foot 6 inches long, 1 foot wide, and 4 inches deep, outside measure, inserting the cuttings in these as closely together as possible without literally crowding them one upon the other. One of these pans will hold fifty cuttings without crowding, and the pan itself takes up less room than is necessary to hold a dozen cuttings in pots. Next in utility to these pans are wooden boxes, and these are of two sorts:—1st, long narrow boxes made of three-quarter-inch deals, 3 feet long, 6 inches wide, and 4 inches deep, outside measure; 2nd, wider and shorter boxes each 1 foot 6 inches long, 1 foot wide, and 4 inches deep, both kinds having six holes bored in the bottom to allow the water to escape. The former description of boxes will hold four rows of cuttings, the two outer rows touching to the sides of the boxes without actually touching them, and the two inside rows 2 inches apart, and the cuttings 2 inches from each other in the rows. The narrow boxes will, therefore, hold seventy-two cuttings, whilst the wide boxes contain about eighty. These boxes may be made neatly, and if painted green they have a tidy appearance. They are prepared for the cuttings as follows:—A few crocks are placed at the bottom to a depth of from half to three-fourths of an inch, and on these is placed an equal thickness of the rougher parts of the compost, which should consist of turf-light loam two-thirds, and river sand one-third, sifted through a half-inch riddle. With this compost the boxes are to be filled quite level, and in it the cuttings are inserted at the above distances and gently watered. They are then placed in a greenhouse or any other house, heated or not, only they will be a week or ten days later in rooting in a cold house, and will not do so with the same degree of certainty as in a structure with a higher temperature. No more water must be given than is sufficient to keep the soil in a nice healthfully moist condition. A slight bedewing of the foliage is beneficial, and preferable to a very wet state of the soil, which is hurtful to the stems of Geraniums at any time, but more so when they are inserted in the soil to strike root.

By the beginning or middle of October the boxes or pots should be placed on shelves about a foot from the glass, so as to insure a stiff, hardy growth. During the winter the plants will not require watering oftener than once or twice a-week, nor, indeed, so frequently in dull, cloudy weather, no more being given than is sufficient to keep the soil in a healthy state. They should, however, be examined occasionally, all yellow and decayed leaves removed, and the surface of the soil between the plants stirred with a piece of wood. These are small matters, but attention to them is very conducive to the health and vigour of the plants. Air must also be given on all favourable occasions, admitting it early, with the thermometer at 45°, and closing early, so as to shut in as much sun heat as possible, which will lessen the necessity for lighting a fire. Fire should only be employed to prevent the thermometer falling below 40°; though it may sink to 35°, yet a minimum temperature of 40° is low enough to keep Geraniums in good health. The temperature should range from 40° to 45° with fire heat, whilst a rise of 10° or 15°, with sun and abundance of air, is very conducive to health. A gentle fire now and then to dry up damp in dull, moist, or rainy weather, accompanied by ventilation, is also essential to success.

These remarks apply equally to cuttings that may be taken from the last week in August until the last week in September, by which time the last batch of cuttings ought to have been secured. Even that is but a haphazard system of raising bedding Geraniums, and gives plants that are late in coming into bloom in the following season. Besides, some of the weaker and dwarfer kinds, as the Nosegay, and all the variegated sorts which it is desirable

to turn out in a forward state, do not do well at the time of striking, and in the following season in beds, unless they are put in as cuttings by the middle of September at the latest, and this is fully a fortnight later than they ought to be. Stella and Baron Ricasoli, two of the best of the Nosegays for bedding purposes, I like struck in August, and also the variegated kinds, not in clusters in pots, pans, or boxes, but singly in 60-sized pots in the first instance, transferring them to 48's before October; in these they are wintered, potted into 32's in the first week in March, and where there is frame room let them have another shift into 24's in the middle of April, by which time they will be in fine condition, and seldom "look behind them" again. The stronger and hardier sorts we need not be so particular about, for they will strike if inserted any time in September, and tolerably well if put in before frosts cut them off in October. In fact, the time of striking Geranium cuttings depends greatly on the period at which the plants are wanted to bloom in the following season. If an early bloom is desired—say in July and August, the variegated and smaller growers should be inserted in August, about the middle of the month, and the stronger-growing Scarlets about a fortnight afterwards. Then for a late bloom the variegated and smaller sorts of Scarlets will do inserted any time before the middle of September, and the stronger kinds about a fortnight or three weeks later. Such furnish plants for blooming effectively in August and September. I have occasionally made up in the beginning of September a dung hotbed, about 2 feet high, consisting of well-fermented dung, covered it with a two-light frame, and in a week or ten days put on a few inches of pit sand, and placed on this the pots of cuttings. With a mild heat of 75° , and a slight shading from hot sun, I had cuttings struck in ten days or a fortnight, and quite as forward as if they had been struck in August without heat. This was done chiefly because the old plants did not furnish a supply of cuttings sufficiently early for cool propagation in August, and also because taking a large number of cuttings would have detracted from the effect at that time.

In whatever manner the stock of Geraniums may have been struck in the autumn, they should be potted by the last week in February or beginning of March from the pots, pans, or boxes in which they were kept through the winter, selecting for the purpose the size usually known as 32's, and employing a compost of turfy loam two-thirds and leaf mould one-third, with a liberal admixture of sharp sand. This compost will grow almost any kind of Geranium well. By placing a few crocks at the bottom of the pot, and some of the rougher parts of the compost upon them, the necessity of employing a larger amount of crocks will be obviated, and equally efficient drainage will be secured. The plants should be taken up with a small ball if practicable, and potted rather firmly. After potting give a gentle watering, and place in a viney or any house where forcing is just commenced. The slight increase of heat and the moist atmosphere will cause the plants to become quickly established, and they will grow rapidly. Those not having vineries and whole ranges of pits need not pot-off the plants from the cutting-pots so early, but may defer it until the beginning of April.

The plants being potted, and placed in the beginning of March in an increased heat of 45° or 50° by night, they will be stout plants by the middle or end of April, and bushy if due care has been taken to pinch or cut back any that exhibit signs of tall lanky growth; the shoots thus cut back if made into cuttings will root quickly, and will make nice, though small, plants by bedding-out time. Some cuttings will grow up with a single stem, and attain a tree-like height before they branch, such should be stopped at the fourth leaf above the soil, and this will cause side shoots to be emitted. It is a good practice to stop the shoots of those plants requiring it about a fortnight after potting. By the middle or latter part of April the house, especially if a viney, will be too warm and too much shaded for Geraniums, and they not only grow too fast, become long-jointed, and drawn up weak, but are liable to receive a check from which they rarely recover before June. This check is consequent on removing them from a shaded, warm, and damp atmosphere to a lighter, cooler, and drier position. Although there is no better place for wintering Geraniums and forwarding them

in the spring than a viney, the vines of which are annually started in the beginning of March, yet a worse place could not be found for them after the middle of April. A cooler place is much more suitable, such as cold pits, Peach-cases against walls, or between the pots in orchard-houses. Cold pits or frames, however, are the best places, for it is undesirable to encumber fruit-houses with Geraniums; besides, when houses are used for a variety of purposes the cultivator in his endeavours to suit everything is unable to give proper treatment to anything. With cheap glass a house specially devoted to bedding plants would not be costly, and would to a great extent obviate the necessity of wintering them in vineries and keeping them there until they are almost spoilt.

Having the plants in a flourishing condition in 32-sized pots by the middle of April, place them in any light, airy description of house from which frost is excluded, but no artificial heat given. If it is desirable to increase the size of the plants they may be potted in 24's in ten days or a fortnight after having been removed into the cool-house, pit, or frame. In this situation they will require copious supplies of water, but none should be given until it is needed, yet the plants should not be allowed to droop, or the leaves will be prematurely thrown off. A dry atmosphere is likewise adverse to the healthy development of the foliage. If the plants are in frames or pits the lights should be covered with mats whenever there is a likelihood of frost before morning, and in addition to water at the root, a gentle watering overhead night and morning will do much towards insuring good plants. Abundance of fresh air, indeed full exposure to the sun, is of paramount importance, for, unless the plants are capable of enduring this before planting out, they will cause nothing but disappointment for some time afterwards, in consequence of their yellow appearance, and arrested growth. They should, therefore be exposed to the atmosphere for some time previous to planting out, and be in no wise affected by cold, sun, and dry air. Thus duly inured to light, &c., the plants will require more room by the last week in May, or beginning of June, and should then be planted out in the beds. These should have been dug deeply in autumn, a liberal amount of vegetable matter worked into the soil, and be again forked over a few days before planting.

With regard to planting Geraniums, some think them best plunged in the pots, whilst others say they should be planted out. I have no doubt that according to circumstances the advocates of both systems are right, but it happens that what will answer in one place will not do at another. Where the soil is light, dry, and but moderately rich, the plants are best planted out, for the very nature of the soil acts as a sort of check to over-luxuriance, and they are, therefore, prolific in bloom and foliage; but in rich, moist soils, which have a tendency to stimulate the plants into growth without giving a corresponding amount of bloom, keeping them in pots acts as a check to over-luxuriance, and they grow less, but bloom more profusely, if plunged instead of planted out. Seasons also exert an influence in this way. In wet seasons the plants are best in pots, whilst during a dry season such as the present, we would find them in much the same condition when we took them up in the autumn as when we plunged them in the pots in May and June, unless they were daily watered. It is admitted by all, that close planting is preferable to thin, for whilst plants treated in the latter way afford but a poor and late return, the others are covered with an early and effective bloom.—G. ABBEY.

(To be continued.)

EXPERIENCES OF A COUNTRY PARSON.

THERE is this advantage in writing the name and address at the end of an article—viz., the public can go to the garden and see "if these things are so." Moreover, it is a security against wilful misdirection.

On four following days these distinguished persons came to review things here—namely, Mr. Kelway, jun., nurseryman, of Langport, Somerset; H. Davis, Esq., Warmminster; H. C. Sturt, Esq., of Critchill; and J. Hanes Calcraft, Esq., of Rempstone, near Wareham; and the Provost of Eton with Mrs. Farquharson and party. They all said they never

saw such a sight as the Peaches (see page 145), and that they admired the foliage and strength of the trees as much as the Peaches.

About 100 had been gathered, beginning on the 9th of August. The crop left on the trees was 450.—W. F. RADCLYFFE, Tarrent Rushton.

At the Blandford Horticultural Show, August 25th, the first prize for Peaches was awarded to the Rev. W. F. Radclyffe; also first prize for Roses, 24 trebles grown on the Manetti stock. Both classes were "open."

OUR METROPOLITAN FLOWER SHOWS.

If I understand the complaints which have been made against the present style of horticultural exhibitions, they are referable to two points—the sameness of their character, and the deficiency of their arrangement. These complaints have been mainly made in connection with the shows of the Royal Horticultural Society at Kensington, and have received some considerable force from the reports that have been brought home by those who visited Brussels during the present year.

We have heard glowing descriptions of the beautiful arrangements, what a fairy scene it seemed to be, and how delightful it would be to have our flower shows arranged in somewhat of the same manner; but I think it is well to entirely dissipate such notions.

We are often told, also, that "they manage these things better in France;" and although I did not see the Brussels Exposition, yet I have seen that which is organised by the Société Impériale d'Horticulture at Paris, and very pretty indeed it was with its parterre and its beds; but as an exhibition of the skill and science of gardeners—bah! Why, there was not a dish of fruit there that Mr. Solomon would have cared to have had in his shop in Covent Garden; and as to the flowers, they exhibited neither skill nor taste. A number of collections there were, but then the plants were starvelings—Orchids, Cactus, &c., in moveable small pots; so that I feel sure none of those who really value a flower show as we have them now would turn aside to look at these productions.

As to Brussels, there are a few things that our reformers must bear in mind. In the first place the whole affair is a government matter from beginning to end. Expense is not considered. The productions of growers in any part of the world are delivered in Brussels and sent back to their destination free of expense. The trouble of unpacking and the expense of attending on the plants may even be dispensed with; and owing to this, several of our large growers contributed to the success of the exhibition.

In the second place, this Belgian exhibition takes place only triennially; for that, persons may indeed give themselves up to the extra trouble and bother that is occasioned by it; but these same persons would be very unwilling to do so nine times instead of once.

Thirdly, The show is open for a week or ten days. One whole day is allowed for the Judges to go through the various productions, and these Judges are very numerous—a very different state of things to that which prevails here.

In none of these points do I see that it is possible to effect any change amongst us. It is certain that the Chancellor of the Exchequer will not put down to secret service, or any other additional item in the estimates, the cost of providing flower shows for the London folks in the season, and no society will guarantee exhibitors the cost of the carriage of their plants. There is no probability of any society being contented with triennial exhibitions, nor, indeed, would it suit the requirements of those who attend the shows. And the experience of this present season evidences that it is out of the question to hope to prolong our great exhibitions for more than one day; for when the expense of bringing up these collections to the place of exhibition is considered, and also the number of assistants who are required to attend on the plants, the cost of another twenty-four hours in London to those who come from a distance, especially in the case of amateurs, would greatly deter people from coming forward in any future improvement that may be made. I think, therefore, that it would be well for people to keep

out of their minds any idea of taking the foreign exhibitions as models or guides.

Can nothing, then, be done? Let us see. The points are whether any better arrangement of the plants can be made, and whether the sameness of the exhibitions can be remedied. *Seniores priores.* I will take, therefore, the Royal Horticultural Society first; and I daresay I shall write a very unpalatable thing, but which I believe many besides myself think—that there can never be a *beautiful* exhibition at South Kensington; and for this simple reason, that there is no place to hold it in.

I understand, whether rightly or not, that Mr. Henry Cole, who seems to be the *Deus loci*, now says that no tent shall be used in the gardens, as it is unsightly, and that hence the fine "mast tent," as Mr. Murray delighteth to have it, was erected outside; and I ask, Where, then, can an exhibition be arranged? "In the arcades," will be the reply of the "great Government-boilers" men. Who is there that does not see at once that if this be indeed the only answer to be given the case is hopeless? The light in those arcades is all side light, and any artist knows perfectly well that that is fatal to the good effect of colour, whether in pictorial or natural objects. Then, again, the arcades are so narrow that it is impossible to place plants advantageously; while the asphalt flooring is so conducive to the generation of dust, that in a very short time the crinolines sweep up and disseminate a steaming cloud of it, while draughts are incessantly careering up and down, to the imminent peril of throats and lungs, and to the certain injury of plants.

Prizes were offered this year for the best arrangement of plants for a greenhouse, and they were placed at the end of one of the arcades, and I think Mr. Veitch could tell a tale of the state of his plants from the draught that they caught from the staircase.

No one can disparage the plants that are brought to South Kensington, there are generally enough of them to make up two or three shows; but, at the same time, I have never seen that either in the conservatory or in the arcades they have had justice done to them; and whatever success has attended the exhibitions has been due to the plants and not to the arrangement.

The Royal Botanic Society and the Alexandra Park Company hold their shows under tents; and there can be no question that this is after all the only way in which flowers can be seen to advantage. Of course you are dependant on weather, and so you are for everything of a similar character in this country; but the Botanic Society has tried it for years, and has found in the long run that their exhibitions have paid and paid well. I believe the unanimous testimony of those who frequent the metropolitan flower shows is that the Botanic holds the foremost place for beauty—the undulating character of the ground, the green banks (showing up the colour so well), the softened light through the canvass, all conduce to make it admirable. It is not perfect, and when I come to speak of improvements I may say where I think these may be made. The plan, too, of separating the cut flowers in a long and narrow tent, where they can be displayed singly, is another excellent arrangement.

There remains, then, the Crystal Palace, but this is *sui generis*. The arrangement there is of the simplest character; but the beauty of the place itself, the noble expanse of light, softened by the canvass stretched over it, give a charm to it which to some extent relieves its formality, while in no place are the facilities for seeing the productions so great, owing to the width of the transept and the ease with which numbers of persons can promenade at the same time.

I have thus endeavoured to give my impressions of the present state of the London exhibitions, the more necessary in that I find many wild notions propagated about them. Thus, with all due deference to Mrs. Ellis, her islands of beauty for which she pleads are impracticable, at any rate at Kensington, and the same may be said of Sir Joseph Paxton's recommendation about the fortnightly meetings, at least beyond what the Floral Committee now has. He forgets that when those Regent Street meetings used to be held horticulture was in a very different position, and that any one coming to London now can see at Messrs. Veitchs', Lows', Williams's, the Hendersons', or any of the great London nurseries, a much better collection of those plants

which may be in season than it would be possible to collect together in London.

I have dwelt somewhat at length on this point, because I believe that to attempt changes which are impracticable is to miss the object altogether; and the calling together of these various committees, and asking the opinion of the most experienced growers, while at the same time the determination has been come to that no change shall be made in the most important point—viz., where the exhibition is to be held, is very much like the Prussian dodge of sending an ambassador to a conference, while all the time it has been determined to gobble up the unfortunate provinces that once belonged to Denmark, but are now “nobody’s child.”—D. Deal.

THE ROYAL HORTICULTURAL SOCIETY’S NEW AND RARE PLANT SHOW.

The subjects exhibited having for the most part been before the Floral Committee, as well as at most of the metropolitan shows, and duly reported on at the time, it will only be necessary to notice a few of the most remarkable.

Mr. Bull, who was the principal exhibitor, sent the female *Aucuba* in fruit—a plant of the green-leaved type. This we believe is the third time the plant has fruited in Europe, Mr. Standish, of Ascot, being the first to show it producing its ornamental coral red berries. Mr. Bull also exhibited the male plant hitherto so scarce, *Aucuba himalaica*, and several varieties of *Eurya* and *Euonymus* which have been noticed before. *Saccolabium Dayi* in his collection, with mauve and white flowers, appeared to be a desirable acquisition; and *Gesneria Radiance*, with rich velvety crimson and green-mottled leaves, was very showy. *Vallota eximia*, having bright light scarlet flowers with a light centre and conspicuous yellow anthers, attracted considerable attention on account of the brilliancy of its colours.

Mr. Linden, of Brussels, sent a few plants, of which the most remarkable was *Rogiera gratissima* with leaves and flowers somewhat resembling those of the *Laurustinus*, the buds are pink and the flowers of the same colour but paler. Being very free flowering it promises to be a great acquisition. Of the others the most remarkable were *Maranta picturata* with olive green leaves, distinctly marked with white for some distance on each side of the midrib, and with a pencilled band of the same hue at some distance within the margin; *Cyanophyllum cinnamomeum* with cinnamon-coloured stalks; and *Doryopteris Alcyonias* with bold dark green fronds.

From Messrs. Jackman & Son, of Woking, came several plants of their fine new hybrid Clematises rubro-violacea and *Jackmanni*, together with coloured drawings of the flowers; and we can safely predict, from the richness of the colours, that these beautiful hardy climbers will be extensively grown.

Messrs. A. Henderson & Co. contributed the variegated *Aralia Sieboldii*, *Gardenia florida variegata*, *Oreopanax dacrydylifera*, and *Rhyncospermum jasminoides variegatum*, all of which have been previously noticed; also, new *Caladiums*; Messrs. Herbst & Stenger, Richmond, an excellent collection of Japanese plants, the *Vanilla* plant, the *Custard Apple*, and *Irresine Herbstii*, with bronzy dark crimson leaves, having bright midribs, which is likely to prove useful for bedding; and Mr. McArthur, Maida Hill, two nice plants of *Bonaparteja juncea filamentosa*. Lastly, Mr. T. Ingram, gardener to Her Majesty, at Windsor, sent Japan Lilies, including *L. auratum*, *Bougainvillæa glabra*, *Enomysus japonicus aureo-variegatus*, with shining dark green and yellow leaves; and some other plants.

A collection of plants, including some of Mr. Weir’s recent introductions from South America, came from Chiswick Garden; the Cotton plant (*Gossypium vitifolium*), presented by Major Trevor Clarke, of Welton Place, Daventry, was also shown in the conservatory, as well as the beautiful *Peristeria elata*, of which the flowers bear so striking a resemblance to a milk white dove.

We consider this Exhibition a step in the right direction, but, as usual now, it is spoilt by the muddling and ill-management.

When exhibitors of plants which have been long in the country, and which can be replaced with comparative ease

in case of accident or injury, will not allow their specimens to remain during a second day’s show, how could the possessors of novelties and rarities be expected to expose them to an ungenial atmosphere, not for two but several days? If any such expectation had been formed it was wofully disappointed, for Messrs. Veitch, Lee, Standish, Williams, and others, abstained from putting in an appearance.

As an inducement to exhibitors one-fourth of the receipts on the first day was to be divided amongst the holders of certificates, and another fourth according to the space occupied, but as at no time during the afternoon could there have been more than fifty persons present, and probably not half of them paying for their admission, the certificate-holders cannot be congratulated on their prospects of a money reward.

We have much pleasure in putting it on record that although 152,962 persons, a large proportion of them children, visited the gardens on Friday last, the anniversary of the late Prince Consort’s birthday, no damage was done beyond a few sprigs of Geraniums being inadvertently broken off. The grass, and especially that on the slopes, suffered considerably, but that, of course, was only what might have been expected with so large a concourse of visitors.

HORTICULTURAL PRIZES, AND FOR WHAT THEY SHOULD BE AWARDED.

In the Number of the Journal published on the 16th inst. I observe an article written by Sir Joseph Paxton on flower shows, &c., on which subject I should have ventured to send you some remarks a long time back, had I not been diffident, as an amateur, of intruding on the notice of those more learned and practised than myself. I now take the opportunity of following so excellent a leader, and offer my ideas for the consideration of your readers.

Sir Joseph’s remarks on the present practice of supplying the market I think must strike every one: nor do I think it in the least surprising that our continental neighbours give us the name of a nation of shopkeepers, looking at the fact that our nobility and gentry are becoming wholesale poulters and greengrocers. On the game question not so much is to be said. It is essentially a wild production, and cannot be supplied but by large estates and domains. Still the “utile” is now-a-days pursued very much to the exclusion of the “dulce”; and although, after one has enjoyed for some days the pleasant society and profuse hospitality of an old friend, and has had his taste for slaughtering helpless creatures fully gratified, he can scarcely expect to take away all the spoil that may have fallen to his unerring gun, still I have heard many confess slight feelings of disappointment, both at the quantity and quality of the share allotted to him by the head keeper, and wish for the good old times back again.

In the matter of garden produce the case is more serious, as it directly interferes with an important branch of industry, in itself subject to so many casualties from the vicissitudes of climate and seasons as to require all the help possible to render it remunerative.

The subject on which I more particularly wish to make some remarks is that of flower shows and their prize awards. Their main object is the encouragement of gardening, and I think that some alterations might be well introduced in furtherance of this end.

First and foremost, I would disqualify any collection of specimen stove and greenhouse plants from competing for a prize after it had once made the run of the season, for there are very few who have had much experience in the metropolitan exhibitions, who cannot predict as soon as the schedules are published who will be the fortunate competitors, and might even say what plants will make their appearance. It seems to me that the prizes in these classes should be more divided, and awarded to the best collections of young plants of not more than two years growth, so as to be *bona fide* the result of the care and knowledge of the party growing them, for as the matter now stands the prize often falls to him who only shows, and not to the one who grows the plants.

The possession of noble specimen plants can only be ar-

rived at after the expenditure of much care and experience for three or four seasons, or by purchase; and it does not seem to be conducive to the encouragement of the young gardener that such plants should be allowed to bear away the reward season after season, to the exclusion of others of less age, not from want of skill on the part of the grower, but simply, as the Americans would say, because the latter were not raised quite soon enough. As the matter now stands, in order to carry out the present utilitarian mode of procedure, in lieu of the employer paying the gardener it ought to be the reverse—the gardener to pay such a per-centge on the amount of his yearly prizes in the ratio of the number of valuable collections placed under his care.

I have a nice little collection of Camellias and choice Rhododendrons, but if an early spring exhibition were started I could not venture to send my plants, when I know that my neighbour, who purchased his collection at the sale of Messrs. Chandler's stock, intends exhibiting his magnificent specimens; and yet all my plants have been grown under my own personal superintendence, whilst the Camellia fancy was never developed in my friend until after he had admired my little plants.

In the second place, I think that it would be a valuable means of encouragement to appoint judges to visit the respective establishments of those desirous of competing, and that prizes should be given to those who could show the neatest and best furnished places, taking into consideration the means and appliances at command. This would, I think, be a far better test of the real talent and skill of a gardener, for I have more than once heard a complaint that the preparations for exhibition take up so much time that other branches are neglected.—C. M. MAJOR, *Cromwell House, Croydon.*

ORCHARD-HOUSE EXPERIENCE—ESPERIONE VINE.

LIKE many others of your readers I have for some years past found much pleasure, but, I regret to say, little profit in the shape of abundant crops of fruit from the culture of pot trees in an orchard-house. I have failed to obtain anything like fair crops; but I feel quite sure that it is to be done, if one only sets properly to work about it.

Like your correspondent "A. B." I visited early in July the nurseries of Mr. Rivers, and, like him, was aghast to see the magnificent crop of Apricots in pots, especially as I last year saw very light crops at Mr. Pearson's, and heard from our mutual friend Mr. Brown, of Lenton, that, though he did so well with Peaches and Nectarines, he could not succeed with Apricots. My visit to Sawbridgeworth convinces me that orchard-house trees in pots have in almost every instance been too sparingly supplied with water and rich top-dressing. I have been using wool-dust (the sweepings of a woollen mill), saturated with sewage, and I find in the course of a month that the top-dressing is completely netted with the root-fibres.

I cannot agree with Mr. Bréhaut that Pêche Abec is a bad cropper. I obtain a good crop, but the flavour is not so good as any others I have. Early York I have had this year superb in size and flavour, but a light crop. Early Grosse Migonne has borne a very good crop; it is of good flavour, and a most handsome Peach. Salway does not seem to do well. The tree makes very vigorous wood, but the fruit does not swell off as it should. Walburton Admirable has dropped most of its fruit, and did so last year, though apparently in vigorous health. Of Early Newington Nectarine I have had some magnificent fruit. Violette Hâtive Nectarine is bearing a very large crop, not yet ripe, but coming on day by day, and looking most tempting. We have a Peach in this neighbourhood which I cannot find in any of the fruit catalogues by name—Cox's Seedling, a very early, delicious Peach, and an enormous cropper. I hope to send you some next year for examination.

Will some of your correspondents be good enough to give their experience of Esperione Vine as a stock for grafting on or inarching? In a cool viney I have a Vine of it that has been planted about eighteen years; it carries this year seventy bunches averaging 2 lbs. each, which are now colouring. On some of the laterals at the ends of the rods

there is now a second crop of bunches, which are setting. Last year it was the same, and the second crop (only a few bunches), ripened thoroughly without fire heat. Is not this unusual?

The vigour of this Vine is extraordinary, and I have great difficulty in restraining it. I purpose next year to introduce grafts of a better sort (Muscat Hamburgh), shall I do right?—M. B., North Devon.

[The caterpillar found at work on the unripe Peach in the orchard-house was the larva of *Mamestra persicariae*, and out of place accidentally, the fruit not being its proper food.]

LIVERPOOL BOTANIC GARDENS.

IN "Doings of the Last Week," I lately alluded to the great beauty of the Liverpool Botanic Gardens last year. I intended a description of them, and Oulton Park, and other places, to have appeared before now, but could not get time for the pen to do what the head and the will wished. I believe that this trying season has much taxed the time and opportunities of many gardeners as well as myself. The ribbon-borders at Oulton, and the artistic arrangement at Liverpool, were exceedingly fine, and grand too, with the rain descending in torrents. Perhaps I may see them again before attempting to do justice to their beauty.

I believe that whilst human nature is what it is every place will have its own difficulties, whether it be a private or a public establishment. The success, however, of all public establishments of a popular kind (and the Liverpool Botanic eminently combines the scientific and the popular), will greatly depend not merely on the taste and genius but on the agreeable and gentlemanly manner of the superintendent. It is delightful to find that amid the difficulties of serving such a number of masters Mr. Tyerman has succeeded in securing the esteem of the Corporation, and the respect of the inhabitants generally. Long may he be spared to diffuse a ripening and bettering influence; for I had oral evidence in various quarters that his efforts were as well appreciated among mechanics, and porters, and cabmen, as among the more genteel classes of society.

It is so pleasing to find the services of a public officer duly appreciated, that I take the following from the columns of the *Liverpool Daily Courier* for the 18th of August:—

"Yesterday, the annual official inspection of the Liverpool public squares and gardens provided for the recreative pleasures of the inhabitants of this large and populous town took place, and this municipal duty was performed by the committee upon whom the highly interesting work of maintaining the gardens devolved. The committee met at an early part of the afternoon, and commenced their duties with the visitation of the various squares. These include the Great George Square, St. James's Mount, Falkner Square, Abercromby Square, and Sheil Park; and we have the gratification to state that the committee were highly pleased with the condition of the whole of these public places of resort by the inhabitants of the districts in which they are located. There was a perceptible improvement in all of them, and with regard to the artistic arrangement of the flowers, the utmost credit was reflected upon the Curator. These squares, which so advantageously enlarge the lungs of the borough, and tend so greatly to the promotion of the pleasant recreation of the inhabitants, are a very important feature in the sanitary character of our local government; and it is very gratifying to find that they have not only been maintained in their full force of efficiency, but that an actual improvement is obvious to the most superficial observer. The principal object of inspection, however, was that popular place of entertainment known as the Botanical Gardens, entrusted to the horticultural skill of Mr. Tyerman. Here the committee arrived in their tour of inspection about five o'clock in the afternoon. They consisted, as usual, of the members of the finance committee, and some other members of the Corporation, who were invited to take part in the inspection; the Mayor and the ex-Mayor (Mr. R. C. Gardner), and about a dozen other of the municipal authorities being present; the Rev. H. Higgins, and other gentlemen to whom the invitation was extended, were also amongst the party.

"The Botanic Gardens, it is well known, are the most

interesting and also the most popular of the various places of public resort provided at the expense of the Corporation of Liverpool. It is, therefore, a matter of great importance to the inhabitants that they should be maintained in a manner adequate to their requirements. In the respected Curator of the gardens, Mr. Tyerman, we have no hesitation in saying that the Corporation and the public possess an official who, in botanical science, is capable of realising their expectations to the utmost. Although the season is rapidly advancing into "the sere and yellow leaf," the gardens still present the most attractive appearance; the beds, the artistic arrangement of which is admirable in the highest degree, abounding in the gayest and most enchanting combination of colours which floricultural skill could possibly display. The Botanic Gardens, with the extensive park adjoining, form certainly one of the most welcome and delightful boons to the people of Liverpool; and the high appreciation in which they are held is sufficiently indicated by the fact, that the attendance of the public includes on ordinary occasions as many as eleven thousand persons. On Thursday evenings a military band considerably enlivens the scene, and adds very appreciable charms, of a musical character, to those which Flora contributes. It will, no doubt, be as gratifying to the public as it is creditable to the skill and attention of Mr. Tyerman, the excellent Curator, to learn that on their annual inspection yesterday the committee found that the management of the gardens was in every respect unexceptionable, and that both in regard to the selection and arrangement of the flowers and plants—which, by the way, we may state, without fear of contradiction, would creditably vie with any public garden in the kingdom—the utmost care and skill had been exercised with the most successful result. The pleasures of the promenade made by the committee were agreeably enhanced by the musical performances of the band of Orphan Boys, who played an admirable selection of music on the grounds; and we need scarcely say that the duty which devolved upon the committee was throughout of the most interesting description."—R. FISH.

ORNAMENTAL GRASSES.

(Concluded from page 125.)

ANNUAL GRASSES.

A COLLECTION of the smaller species grown in pots is highly interesting, and gives a diversified appearance to mixed borders, the lively green shades and graceful forms of these Grasses adding to the beauty and variety.

Most of the species are very desirable for bouquets in a fresh state, and when cut and dried, if mixed with Everlastings, they are valuable for winter bouquets and in-door decoration generally.

The soil most suitable for Grasses is a moderately rich loam, neither too light nor too strong, but of intermediate quality. It may be formed of mellow loam two-thirds, leaf mould one-third; the whole well mixed, chopped with a spade, but not sifted. If the loam be light and poor one-third of moderately-decomposed manure may be incorporated with it in place of the leaf mould. Keep this compost under cover for a few days, so that it may handle the better in the potting.

The pots to be employed should be large enough to allow of the seed being scattered thinly, for nothing is so destructive to seedlings as thick sowing, for it causes them to spindle up, and to flower weakly and prematurely. Drain the pot well, fill it with the compost to within half an inch of the rim, scatter the seed after levelling the surface, and then cover lightly—not deeper than just to hide the seeds—with fine soil. Place a neat label to each pot, not a large one (for nothing is so out-of-place as a large label to a small plant or pot), with the proper name of each Grass legibly written upon it; for it is a great drawback to grow a plant and not be able to tell the name of it.

Place the pots in a house with a gentle heat, such as a viney, or frame employed for striking cuttings or raising half-hardy annuals. The soil should be kept well watered, so as to secure a speedy germination; but too much moisture is apt to rot the seeds, especially when they are old; the soil should, therefore, be kept just healthfully moist. When

the seeds have germinated and the plants appear, be careful to have the pots near the glass; and when the plants are fairly up, place the pots in a greenhouse or frame, so as to prevent the seedlings becoming weak from excess of heat, giving air freely, and watering sufficiently to maintain them in a growing state.

After they are of sufficient size to handle, transplant some of the largest with balls into pots filled with the same kind of compost as for the sowing, employing pots of various sizes according to the strength or height of the species. Small kinds, as Agrostis, may be grown in pots 6 inches in diameter, and others in sizes proportionate to their growth. It is essential to distribute the seedlings in threes in the centre of the pot for a specimen—that is, the small patches of plants standing at the points of an equilateral triangle, varying in distance between patch and patch as the species is strong or weak, or a large pot employed. The seed-pots have the holes made in transplanting filled up, and they, as well as the newly-potted plants, are watered, and placed in a cold frame or returned to the greenhouse, watering and sprinkling overhead night and morning with the syringe, so as to secure a healthy growth. Supposing the seeds to be sown in the middle of March, the plants will be in a forward state by the latter part of April or beginning of May. Those in the seed-pots may then be transplanted into spaces in mixed borders in places not shaded or under the drip of trees, nor in spots liable to become dusty during the summer.

In planting out it is desirable to part the plants into small pieces, placing them in patches of five or more together; watering them afterwards daily if a dry period ensue until they become established, and again in dry weather after they are advanced for flowering, with clear water both at the root and overhead, sprinkling the tops being often of as much importance as water at the root, especially in smoky, dusty places, where the pores of the plants are often choked by the accumulation of dirt. An occasional application of weak liquid manure will greatly tend to improve their flowering; and though these plants have not the grandeur of a Dahlia, Hollyhock, or some other ornaments of the garden, they, nevertheless, deserve these little attentions. If they are not thought worthy of the same care that is accorded to other plants, they are not worth their room, and therefore ought to be discarded from the garden altogether. It is the haphazard system of growing annuals that has caused many persons to look upon them as nothing but weeds. Such, also, is the case with the majority of herbaceous plants. They receive no attention whatever that may be termed "cultivating a plant," and they are discarded because not looked after. Now, I do not think there are any plants so likely to please as a selection of the best Grasses grown in pots; and though I may be a little prejudiced in favour of them, yet I have found them much admired by those for whose pleasure they were grown.

If desired to have a succession of spray for bouquets (and what is equal to Grasses for the purpose?), we plunge half the number of pots to the rim in coal ashes in an open situation out-doors, sprinkling them overhead every evening, except when a shower falling in the day renders it unnecessary, and watering them daily or bi-weekly at the root as occasion may require, so that they may never lack that element, nor are they, on the other hand, deluged with it.

Every second watering may be of liquid manure highly diluted, or guano water, at the rate of 1 oz. to the gallon of rain water, which will do much to maintain the foliage in a green state. The pots, bear in mind, must not be crowded together, but distributed at such a distance as to afford sufficient space for the full development of the foliage, and for its being duly acted upon by the all-important influences of light and air. Under these conditions the plants will flower finely, and may be removed when in bloom to vases in doors to mingle with flowering plants, among which they have an excellent effect.

If seed be desired one or more of each kind should be kept for the purpose, for they will not produce seed worth saving in halls, drawing-rooms, &c.

I have passed over those we have in pots in the greenhouse, which I will now revert to. They being potted off will need water and copious syringings morning and evening, beyond which they require no different treatment from other plants. They bloom a month earlier than those out-

doors, and are alike interesting, curious, or beautiful, whether left in the house to bloom or removed for decorating rooms.

Some of the annual Grasses are only half-hardy; they should, therefore, be sown from the middle of March to the last week in April, in pots or pans, placing them in a slight hotbed, and when the plants are strong and well hardened off transplanting them into the open borders, or potting them off if it be desirable to have specimens in pots. Irrespective of raising and growing them in pots, the hardy species may be sown in the places where they are to remain, in the first week in April, either in patches or in lines, scattering the seeds rather thinly, and just covering them with fine soil. Should the weather be dry after sowing, it is necessary to water the patches in order to insure germination, and to keep a constant moisture in the soil, place an inverted flower-pot over the seeds, or a thin layer of moss, or a mat, the former and the last to be removed at night, or during the absence of sun. After the plants appear remove the pots or whatever else may have been employed to keep the soil moist, and when of sufficient size to handle thin the seedlings, distributing them, or otherwise allowing room to spread. They should be thinned to at least an inch apart if expected to assume their natural character. During dry weather they should be well watered, or their foliage will turn yellow and die off at the points, and the flower-spikes will rise prematurely, and be weak and poor for the lack of this element. In fact, they cannot have too much water, if only they have room to grow, and the soil be of such a nature that stagnant water cannot lodge in it, and so render it a bog.

The species bloom at different periods; they should therefore be watched, and any that are desirable to dry for winter should be cut either just before or just after the blooming is over, for if cut too early the flower-stalk has not sufficient strength to support the head, nor are they in full character, and when cut when the seed is nearly ripe they are too brittle, and more straw-like than when gathered and dried earlier. The best time, in my opinion, is immediately after the blooming, selecting a dry day, and then drying them in the sun. Some dye them a variety of colours after they are dried, which adds materially to their beauty as winter ornaments, otherwise dried Grasses are rather tame subjects for winter bouquets.

Appended is a list of some of the most ornamental species; the half-hardy kinds, which are to be raised and forwarded in heat prior to planting out, being distinguished by an asterisk.

**PASPALUM ELEGANS*.—Pretty, 1 to 1½ foot.

LAGURUS OVATUS (Hare's-tail Grass).—1 foot. Curious and ornamental.

PENNISETUM LONGISTYLOM.—A very interesting and graceful Grass, 1½ foot.

P. ITALICUM.—Pretty, 1½ to 2 feet. These two being from the south of Europe should be raised and forwarded in heat if intended to flower the first year. The first is very fine for a neutral or centre bed, the plants being raised and grown on one season, protected from frost in winter, and planted out in the spring of the following year. Its graceful foliage and elegant inflorescence entitle it to a prominent position amongst its congeners.

HORDEUM JUBATUM.—A curious Barley-headed Grass, having a rosy tint. It is a biennial if not a perennial, flowering the first year. 1 to 1½ foot.

**SORGHUM BICOLOR*.—Tall, yet graceful. 2 to 3 feet. This will not do outside in cold exposed localities.

**TRICHOLENA ROSEA*.—Beautiful, the inflorescence having a rosy tint. 2 feet. The same remarks apply to this as the preceding.

SETARIA MACROCHETA.—Fine and graceful. 2 feet.

AVENA STERILIS (Animated Oats).—Very curious. The seed-vessels resemble a fly, and are furnished with a long, jointed awn, which twists about when subjected to moisture or dryness, and it is on this account an excellent hygrometer. 2½ feet.

CERATOCHLOA PENDULA.—Pretty. 1½ to 2 feet.

**CHLORIS POLYDACTYLA*, *RADIATA*, *BARRATA*, *FIMBELIATA*, and *SUBMUTICA*, are all remarkable on account of their formation, *A. radiata* being very curious. 1 foot.

CHEYSURUS AUREUS.—A handsome variety with golden spikes. 6 inches.

ANTHOXANTHUM GRACILE.—Graceful. 6 to 9 inches.

BRIZOPEUM SICULUM.—Elegant; foliage shining light green, plaited inflorescence. 9 inches.

ELEUSINE CORACANA (Five-horned).—Curious. 1½ to 2 feet.

E. INDICA.—Graceful, with immensely long horns. 1 foot.

E. OLIGOSTACHYTA.—Very singular and striking. This is three-horned.

ELYMUS CAPUT-MEDUSA.—Graceful. 2 to 2½ feet.

AGROSTIS ELEGANS.—A very pretty species of the lightest possible appearance.

A. LAXIFLORA, graceful; *A. PLUMOSA*, flowering in plumes; *A. FULCHELLA*, with nothing more pretty about it than the rest of the Agrostises, are all charming for bouquets either green or dried.

A. NEBULOSA.—One of the most beautiful if not the most graceful of the smaller Grasses. 1 to 1½ foot.

EGILOPS CYLINDRICA, with curious knotted inflorescence, is both curious and pretty. There is a prevalent opinion that it is the wild form of the cultivated Wheat; but having grown it some years I am certain man never was indebted to this plant for the "staff of life." Botanists refer the wild Wheat to a form of *Egilops ovatus*—viz., *Egilops triticeoides*. I may state, however, that *Egilops ovatus* does not assume another form so far as my experience goes; and as for the degeneration of the Wheat plant into an *Egilops*, as asserted by Galen, it seems to require confirmation. Should any of your readers come across the alleged wild type of the Wheat plant (*Egilops triticeoides*), producing seed, I should esteem it a favour if they would send me a few seeds through the Editors.

ERAGROSTIS CYLINDRIFLORA.—Pretty. 1½ foot.

E. ELEGANS (Love Grass).—Fine. 2 feet.

E. MEGASTACHYTA.—Elegant and very pretty. 1½ foot.

BRIZA GRACILIS.—Very pretty and curious. 1 foot.

B. MAXIMA OR MAJOR (Large Quaking Grass).—2 feet.

B. GENICULATA.—A charming species. Fine for bouquets. 9 inches to 1 foot.

**HOLCUS SACCHARATUS*.—A stately plant, alike graceful, elegant, and ornamental. It produces a fine effect in mixed borders, and is desirable on account of the changeable character of the foliage and its delicate perfume. There are over a dozen varieties of the species all more or less advances on the parent, except that they do not grow so tall. It should be sown in heat, and put out in a forward state, otherwise it will not flower.

ZEA OR INDIAN CORN is a stately Grass for mixed borders, being bold and handsome in foliage, attaining a height of from 3 to 7 feet. There are numerous varieties varying in habit and with different coloured heads of corn. For these to do well it is desirable to sow the seeds, three or so in a 24-pot, and grow the seedlings in a gentle heat, so as to plant them out in May in a forward state.

G. ABBEY.

At some future time I may add an article or two on "Cultivated Grasses," especially those employed for laying down lawns, with a few hints on the best kinds for parks, meadows, &c., about gentlemen's houses.

RULES RELATING TO HYACINTHS GROWN IN GLASSES.

THESE rules may be learnt in five minutes, and if followed, will, I am persuaded, be attended with satisfactory results.

1. If you choose your own bulbs, look for weight as well as size: be sure also that the base of the bulb is sound.

2. Use the single kinds only, because they are earlier, harder, and generally preferable for glasses.

3. Set the bulb in the glass so that the lower end is almost, but not quite, in contact with the water.

4. Use rain or pond-water.

5. Do not change the water, but keep a small lump of charcoal at the bottom of the glass.

6. Fill up the glasses with water as the level sinks by the feeding of the roots and by evaporation.

7. When the bulb is placed, put the glass in a cool dark cupboard, or in any place where light is excluded, there to remain for about six weeks: the roots feed more freely in the dark.

8. When the roots are freely developed, and the flower-

spike is pushing into life (which will be in about six weeks), remove by degrees to full light and air.

9. The more light and air given from the time the flowers show colour, the shorter will be the leaves and spike, and the brighter the colours of the flowers.—(W. Paul's Lecture on the Hyacinth.)

PROTECTING WALL FRUIT FROM ANTS.

LAST year I was very much troubled with ants, and, although I tried every remedy suggested to me, failed to get rid of them. This year they were equally numerous and troublesome, and commenced their depredations on my Morello Cherries. I at once opened the campaign, determined if possible to conquer them. As I have a great objection to the use of poisons unless under great necessity, I thought I would first try syringing the trees with a decoction of elder. This was a failure. I next tried a decoction of quassia; but although it drove them away for a day or two they soon returned. Pepper was the next application, and that was only partially successful.

They now began a vigorous attack on my Apricots. Here I tried crude gas water poured under the trees against the wall. On examining the fruit the next morning I found an Apricot hanging within 6 inches of where the water had been poured swarming with them.

I thought I must now try poisons; so obtained some corrosive sublimate, strychnia, arsenic, and cyanide of potassium. Each of these I separately mixed with either sugar, honey, or treacle, and carefully placed them under inverted flower-pots, the holes of which I closed to prevent bees from entering. The ants had free access; but with the exception of the solution of cyanide of potassium and sugar, in which I found four or five, I could not discover any dead lying about. At first I thought perhaps other ants had removed the bodies; but a few days afterwards, on examining a piece of paper on which I had placed some treacle and arsenic, I found that while there was no trace whatever of treacle the arsenic remained. From this I conclude, that where the substance employed with the arsenic does not thoroughly dissolve it, the ants can discriminate, and only take that which is agreeable to them.

Finding that poison did not succeed, I placed some soot along the base of the wall. This prevented their getting up; but I then found that they visited me from the opposite side, and many took up their abode in the interstices of the wall.

My last, and I hope my most successful attempt, was with gas tar, but not quite in the manner recommended in your Journal. I first had one of the courses of bricks a few inches from the ground tarred the complete length of the wall; and then, as I thought if tar were put on the trees it might injure them, a slip of carpet was tied round each stem. This was also tarred over so as to completely insulate the bearing part of the tree. Next I daubed some tar here and there on the wall to drive off stragglers, and finally tarred the top of the wall to prevent their return. This has now been done some days, and since then up to the present time I have not seen one on the walls. It is necessary to mix some grease with the tar to prevent its drying, and should the bricks absorb it rapidly a second or third coat would be desirable.

My object in troubling you with these remarks is more to prevent your readers from using arsenic and such violent poisons in their gardens than to show the advantage of tar, as in the latter, I am aware, I am suggesting nothing new. I may mention, to show how dangerous it would be to have poisonous mixtures lying about, that a short time since I placed in my greenhouse, with the intention of killing flies, some treacle and quassia. Shortly afterwards I noticed on two or three of the Grapes some little dark spots. These I found to be the treacle, probably carried by wasps or some of the larger flies. Suppose, instead of using quassia I had employed some strong poison!—AMATEUR.

MESRS. PAUL & SON'S ROSES.—In addition to Mr. W. Paul's and Mr. Turner's Roses, as mentioned at page 146, Messrs. Paul & Son's, of the Cheshunt Nurseries, were requested by the Princess of Wales to be sent to Marlborough House.

NEW BOOK.

UTILIZATION OF MINUTE LIFE.

The Utilization of Minute Life; being Practical Studies on Insects, Crustacea, Mollusca, Worms, Polypes, Infusoria, and Sponges. By Dr. T. L. PHIPSON, F.C.S., London, &c. London: Groombridge & Sons.

The object of this interesting little volume is to give not only a correct idea of various minute animals, which either are themselves, or whose products are utilized in various arts and manufactures, but to inquire whether they "cannot be submitted to culture, and propagated more extensively by artificial means, and thereby the benefits derived from them increased." The contents of the volume are divided into chapters, devoted in succession to silk-producing insects, colour-producing insects, insects producing wax, honey, &c., insects employed as medicine and food by man, crustacea, mollusca, worms, polypes, infusoria, and sponges. We do not object to such divisions, though they might be improved, but we do complain that there is no index. Such a book without an index is almost as embarrassing as an upper chamber without a staircase.

We can only afford space for one extract, but it will enable our readers to form an estimate of the work.

"Many philosophers, from the time of Priestley and Ingenhouz to the present day, have studied the influence of light on vegetables, but few have paid attention to its action upon the animal organism. Thus, whilst Priestley, Ingenhouz, Sennebier, De Candolle, Carradori, Knight, Payer, Macaire, and some others, made manifest the action of light upon vegetable respiration, absorption, exhalation, &c.—in a word, upon the phenomena of nutrition and development in plants, Edwards and Morren were almost the only observers who studied animal life from the same point of view. Edwards showed that without light the eggs of frogs cannot be developed, and that the metamorphosis of tadpoles into frogs cannot be effected in absolute darkness.* Again: Moleschott has recently shown that the respiration of frogs is most active in the daylight, diminishing considerably during the night; and Charles Morren observed Infusoria to evolve oxygen whilst basking in the sunbeams which play upon the stagnant waters they inhabit. Later still, M. Berard took a certain quantity of eggs of the fly (*Musca Caesar*); he divided them into separate groups, and placed them under different coloured glass jars. In four or five days, the larvæ produced under the blue and violet-coloured jars were much larger and more fully developed than the others: those hatched under the green jar were the smallest. The blue and violet jars were found, therefore, to be most favourable to rapid and complete development; then came the red, yellow, and white (transparent) jars; and last of all the green.

"The larvæ developed in a given time under the influence of violet light were more than three times as large as those hatched and reared in green light.†

"The experiments are certainly very interesting in a practical point of view; for if it be true, as it appears to be, that the larger a silkworm is the more silk it will produce, it would be worth while to repeat these experiments upon silkworms, and endeavour to raise a large breed under violet glass.

"Nothing would be easier than to select a portion of some silkworm establishment for the experiment, and to furnish this section of the building with violet-coloured windows. It would, indeed, be interesting to see these violet-coloured panes become as necessary to the silk-breeders as the yellow window is essential to the photographer. In the former instance the violet would serve to allow the chemical rays of light to pass, while the other rays are excluded. In the latter, the yellow is used to cut off these chemical rays, and to let pass the remainder."

* Compare Higginbottom in "Proceedings of the Royal Society," 1862; where some experiments of Edwards are refuted.

† The effects of the sun's rays, when filtered through differently coloured glass, upon the development of infusorial life, has recently occupied Mr. Samuelson. He fitted up a box containing three compartments, covered by a pane of blue, red, and yellow glass respectively, and found that under the blue and red glass infusoria were rapidly developed, whilst under the yellow hardly any signs of life were visible. He then transferred a portion of the infusion from the yellow to the blue compartment, when infusoria very soon made their appearance.

"EYES AND NO EYES."

I BEG leave to thank you very much for the excellent article on "The Education of the Eye," which appeared in your Number of the 9th inst. I hope all the gardeners in England have read it, or will read it. You have given us various articles lately respecting the education of gardeners, but let a gardener be as well educated as he may in other points, if he has not an eye, he is worth little or nothing.

You will see one man sweep out his greenhouse, but he never thinks of removing from the plants the yellow and decayed leaves. Another man walks by a flower-bed day after day, where half a dozen weeds stare him in the face, but he never stoops down to pluck them up. When a master who has an eye in his head points out to his gardener these same weeds and withered flowers, and suggests that the greenhouse and the flower-bed would look better if such eyesores were removed, what answer does he get? "Oh! yes, sir, we shall get to them in a day or two."

The meaning is plain. Most gardeners, even when they have plenty of help, go through their work in a regular circle like a horse in a mill, and so in part they ought to do; but meanwhile they should have their eyes open, and always, every day, be doing a little here and a little there, just as things happen to be wanted. A gardener ought to manage his ground as a housemaid does her drawing-room: she makes all things clean and right every morning, and then in the afternoon walks through the room and puts it in order. This is what a gardener should do with the place he has to keep. If he does not, if he lets his pots be dirty and green, if he allows decayed leaves to hang here, and weeds to grow there, do not let him excuse himself by saying he has not time. Such matters as I speak of take little or no time. Indeed, attention to them will save time in the long run. What the man wants is, not time, but "an eye," and to give a man an eye if he has not one is the hardest thing in the world. I have taken endless trouble with men for years, but all in vain. I sincerely hope that your article may have better success.—A MAN WITH AN EYE.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE August Meeting of the Entomological Society was fully attended for the season of the year, the chair, in the absence of the President, being occupied by the Rev. Hamlet Clark, M.A., who communicated a valuable memoir on new species of Water Beetles, belonging to the genus *Hydaticus*, of Leach, from Australia, China, and the Gold Coast.

A paper was also read by W. C. Hewitson, Esq., containing descriptions of six new and beautiful exotic species of Butterflies from the northern parts of India and the island of Menado, Borneo. Another paper, by Mr. Baly, was also read, containing descriptions of new exotic species of herbivorous Beetles, belonging to the Calopepla and allied genera, preceded by some interesting observations on the geographical distribution of these insects.

Mr. Frederick Bond exhibited a specimen of *Gelechia pinguinella*, a small species of Moth, belonging to the family Tineidae, new to this country, which had been found on the trunk of a Poplar tree near London; also, *Nyctegretes Achatinella*, one of our rarest Moths, of the family Phycidae, captured by Mr. T. Brown near Yarmouth.

Mr. McLachlan exhibited a specimen of a Dragon Fly, *Libellula striolata*, from the south of France, the longitudinal veins of the wings of which, near the base, were dotted with numerous scarlet points, which proved to be minute Acari (*Gamasus Libellulae*), and it was suggested that these parasites had occupied this position in order to obtain food from the circulating fluid within the veins of the wing surrounding the central air tubes of those organs. Mr. F. Smith, however, stated that he had found Acari on the hard horny bodies of Beetles and Bees, where they could not obtain such kind of nourishment.

Mr. J. J. Weir exhibited an albino variety of *Eubolia bipunctaria*, one of the Geometridae, taken on the Southdowns.

Among the donations received since the last Meeting, were the publications of the Royal and Zoological Societies of London, the Royal Societies of Madrid, Moscow, Munich, Stettin, &c.

MR. B. S. WILLIAMS'S VICTORIA NURSERY, HOLLOWAY.

SOME three months ago our correspondent Mr. Earley directed attention to the Victoria Nursery, which Mr. Williams has formed at the foot of Highgate Hill, and we have now the pleasure of presenting our readers with a view of the interior of the simple but elegant conservatory and show-house which has been constructed under Mr. Williams's direction.

This house is 105 feet long, 45 feet wide, and 20 high to the ridge, the sides being about 10 feet in height. The frontage to the road is light and of an architectural character, there being six plate glass windows on each side of the door, separated by columns, and surmounted by ironwork of an ornamental vine-leaf pattern. As regards the general aspect of the interior, our engraving, taken from a photograph, will give the best idea.

The floor is of Portland cement, the paths being marked off by a simply moulded iron edging. The central pathway is 7½ feet wide, and another crosses it at the middle of the house; one of Pulham's terra-cotta fountains, planted with Ferns, being placed at the point of intersection. Another path 5 feet wide leads all round, between which and the glass is a slate platform.

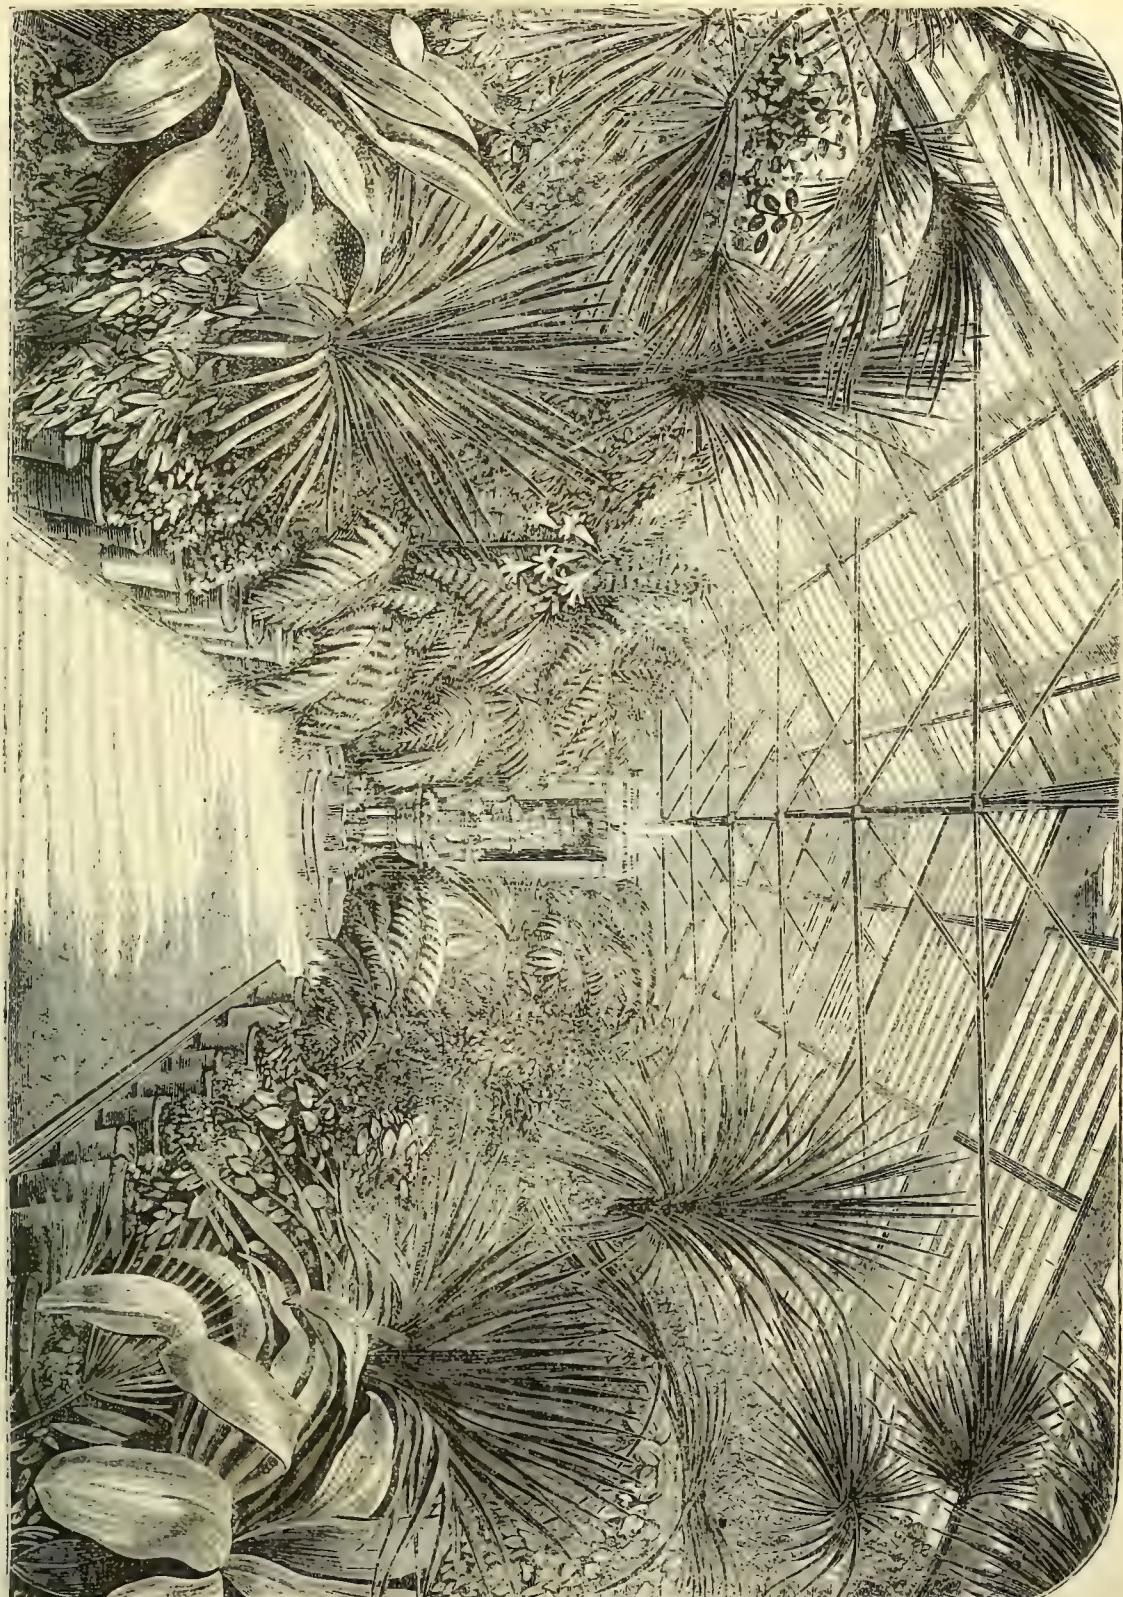

The roof, which is fixed, is supported by eighteen hollow wooden columns and trussed with iron; and ventilation is effected by hinged sashes at the ridge worked by ropes and pulleys, and by side lights opening in the same manner. For heating there are four flow and return four-inch pipes running beneath the slate shelving and nearly on the same level as the floor.

The mode of shading adopted is worthy of notice, for, unlike most conservatories, the tiffany which is employed is placed inside instead of outside the glass. Near the ridge there is a roller between every pair of rafters, on which the tiffany is wound; and attached to the lower edge of the tiffany is a rod running in guides on the rafters. By pulling a rope this rod readily descends, bringing the tiffany with it; and by means of a pulley, when the shading is no longer wanted, the whole is wound up.

We will now take a glance at the contents of the house. On each side of the central path are ranged in match pairs fine plants of *Yucca aloifolia variegata*, *Chamaerops humilis*, *Cibotium Schiedei*, and *Dracaena australis*, two handsome specimens of which, standing some 12 feet high, are conspicuous in our engraving. Then at the fountain, where the main pathway and the cross-walk intersect, are two plants of *Dicksonia antarctica* 6 feet high, one on each side; and occupying a similar position on the opposite side are large specimens of *Latania borbonica*, backed with noble specimens of *Cyathea excelsa*. Further on we come to a remarkably fine *Zamia Lehmanni*, its singular scarred stem 3 feet in circumference; *Marattia elegans*, with seven fronds 5 feet long; and noble specimens of *Cycas revoluta*, *Cyathea dealbata*, and *Yucca Boerhavi*, the last very ornamental and tropical in its aspect. At the end of the walk is *Cibotium princeps*, with fronds extending 12 feet across; and two fine trees of *Araucaria excelsa*, touching the roof, stand sentry on each side of the door of the former residence of Sir Richard Sutton, which constitutes the further extremity of the conservatory. The splendid Indian Rhododendron Nuttalli, which produced such a profusion of its immense white and yellow sweet-scented flowers, and which was a conspicuous object when the photograph was taken, is, of course, now out of flower, but it may be observed figuring prominently in our engraving. The plant was then 10 feet high and 7 feet through, and had as many as ninety flowers on it at one time.

Along the side-shelves were ranged a large collection of Agaves, Yuccas, Dasylirions, &c. Among them were the new *Agave schidigera*, the white cuticle of which appears as if torn from the thick substance of the leaf; *Yucca Stokesii* with large and showy foliage, the singular Australian Grass tree, which Mr. Williams has several times exhibited during this summer at the great metropolitan shows; and in the body of the house was *Dasylirion acrotrichum* with a flower-spike standing 8 feet high.

The other parts of the nursery are not yet completely organised, for walks of increased width are to be made,

and several glass houses to be erected. Two, each 45 feet long and 33 wide, have just been commenced, and besides

already exist. These are variously filled with New Holland plants and Ericas, softwooded plants, and a large stock of Royal Vineyard Vines and Charlotte Rothschild Pines.

THRIPS.

ONE peculiarity of the present remarkably dry season is the swarms of small black thrips which fly about in immense numbers, frequently settling upon our hands and face as we go about the garden. They infest many of the flowering plants, and, in some cases, do a great amount of mischief. Dahlias, Phloxes, Verbenas, and Geraniums, all suffer more or less from their ravages; but they seem to have a peculiar liking for flowers of a rose or pink colour, such as Saponaria calabrica, and, especially, Geraniums Rose Queen and Christine. Wherever there is a plant of either of these Geraniums, in the beds, or singly in the borders, every flower is destroyed as it opens. I have whole beds with scarcely a single bloom, to say nothing of trusses, that is perfect, while beds close by, filled with other varieties, are comparatively unhurt. The thrips find their way inside the calyx, and, under its protection, eat away the base of the petals, the remainder falling down upon the foliage. I have tried repeated applications of Gishurst compound, 2 ozs. to the gallon of water, but that produces little or no effect upon them, perhaps from the fact that they are buried in the calyx of the flower. More than once I have taken off all the flowers and burnt them, thinking the next lot that opened might be free, but the succeeding blooms shared the same fate as the others. The Saponaria suffers in just the same manner, each bloom being destroyed as soon as it opens.

I should like to know whether this state of things is general, and why flowers of this particular shade should be such an attraction to these insects, while those of a different colour, although of the same genus, are comparatively free from their attacks.—J. JONES, Manchester.

GRUBS AT THE GREENS.

WHEN I went to school there came occasionally, once a half year or so, an old gentleman to give us a lecture on chemistry. His experiments were, I am afraid, all we cared about. What was to be heard passed unheard by the majority, but what was to be seen attracted all eyes. I regret to say, also, that we delighted in taking pen and ink sketches of the Professor in various attitudes; his long nose, spectacles, and pointed chin, were attractive to the caricaturist. But what I want specially to remark upon was, the fact that on chemical-lecture days the under masters sat with the boys as learners.

Now, to day I wish to sit with the boys. I write not to inform, but to get information. My Broccoli plants and other plants of that class are attacked by a horrible grub, such as I never had the pain to be acquainted with before. I saw one day, two or three plants leaning on their sides, and looking flagged. On approaching them I found they were all but severed at the part of the stem just below the surface, on examining which stem I found it was bored like a gun. Pulling up the root I scooped away the earth with my fingers, and, lo! a little way down was the offender—a flat, yellowish green grub, curled up in a semicircle. I find all my neighbours are suffering similarly, doubtless the dry season is to blame. I saw a large bed of Lettuces reduced to five. Then, I hear that Onions, Leeks, and Carrots are also attacked. As to my battalions of Winter Greens, they look as if they were General Grant's battalions cut up by Southern cannon balls. If you please, I want to be told a remedy for my plants against these pests, for I am tired of finding them and crushing them on the path, as the cry is "Still they come." I do not care about the scientific name of my enemy, possibly it is "Yellowgreenius grubbensis," the product of "Musca tormentor gardeneri." These names will suffice for me; but I want to exterminate the foe. Lime water has been tried but has failed. Will you befriend your troubled—WILTSHIRE RECTOR?

[What heresy! "Not care about the scientific name!" Now, if you were told the scientific name you might thence comprehend the parentage of the marauders, and though there is no application known which will kill the grubs whilst it does no injury to the plants, yet there might be something sprinkled over the surface of the soil at another season of the year which would prevent the mother depositing her eggs there. However, you do not wish to know

the scientific name, and we will merely say that your "yellowgreenius grubbensis," is known to, and characteristically described by gardeners as the "Leather-coat," for a tough-skinned adversary he is. The only remedy is (without intending a pun), to grub round each plant in a bed so soon as you see that one plant in it is attacked. Such a proceeding only seems tedious, for one woman with an old dinner knife will prove the conservator of a large bed of Broccoli in a single day.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE haulm of Peas, Beans, &c., should be cleared away as soon after the crop is over as possible, and the ground manured and trenched to be in readiness for planting. *Cabbage*, the seedling plants intended to stand through the winter, to be now pricked out in nursery-beds of light soil at 5 inches apart. This will be found of great advantage, by inducing a hardy stocky growth. *Celery*, proceed with the earthing-up according to the demand. Some of the very latest crop may also be planted in rows to stand through the winter. The haulm of Peas laid by now in a dry place is a good material for covering Celery during severe frost. *Endive*, continue to make successional plantations. Some of the first planted out will now be in good condition for tying-up for blanching. *Lettuce*, a small patch of Bath Cos sown now will, if the autumn prove mild, be more valuable than that sown earlier. *Onions*, no time should be lost in storing the crops when fully dry; as the ground from which they are taken is generally used for *Cabbage*, it should be immediately trenched-up. If manure is necessary, let it be laid on the top of the trenched soil and fork it in. If, however, the ground was well manured for the *Onions* it ought to carry the *Cabbage* through, because if too much manure comes in contact with the roots in the autumn, it induces a succulent luxuriant growth, which renders the plants liable to injury from alternations of frost and thaw in the winter. *Radishes*, these may still be sown. *Spinach*, thin out the Winter, the plants to stand at least 8 inches apart, and the ground to be constantly stirred about. Occasional dustings with quicklime will also be necessary if slugs appear. *Tomatoes*, any that are likely to be late should have the leaves that are shading the fruit removed, and prevent the plants making any further growth by constant stopping.

FRUIT GARDEN.

Now that we have arrived at a season which generally matures the more important fruits usually cultivated in our gardens, it may be advisable to mention a few of the necessary precautions to be observed in the storing and gathering of fruit. Peaches and Nectarines should not be allowed to remain on the trees until they are what is termed dead ripe. A little practice will enable a person to determine the degree of ripeness at which fruit should be gathered, without resorting to the common and barbarous way of pinching. Plums should remain till perfectly ripe, the large amount of saccharine matter in the fruit acts as a preservative, and although something may be lost in bulk by their being allowed to remain on the tree, the flavour will not be deteriorated. Such as *Impératrice* and *Golden Drop*, if protected from wasps, may be kept until a very late period in the season. Apples and Pears generally fall as soon as they arrive at any degree of ripeness, that period must be anticipated, and their removal effected as soon as its approach is ascertained. After gathering, the fruit intended for keeping should be laid out in the fruit-room for a week or ten days and exposed to a free circulation of air. The fruit will be found clammy from perspiration, it should then be carefully wiped and laid out thinly in the store-room, which should be kept, as soon as the fruit is introduced, securely closed and protected from the alternations of temperature. If Apples and Pears are gathered carefully without contusion, and sorted at a proper period, so that all defective fruits may be removed, they may be preserved with very little loss, and found in a plump highly-flavoured condition throughout the winter season. When mulching has been used for Peach and Nectarine trees, it should be removed at once, for the fruit is seldom well flavoured if the roots are excluded from the action of the sun and air during the period of ripening. See that the

Strawberries in pots for forcing next season are well cared for, placing them in an open sunny situation where they will have all the light possible, and do not allow them to suffer from want of moisture at the root.

FLOWER GARDEN.

As the numerous varieties of *Verbena* are now in bloom, the best kinds should be selected for bedding out next year, also the particular habit and colour should be noted for the better arrangement of them at planting-out time. The same observation holds good in regard to new *Petunias*, *Fuchsias*, *Pelargoniums*, *Calceolarias*, &c. Give diligent attention to the propagation of bedding-out stock, and get cuttings that are sufficiently rooted potted off at once, keeping them close until they become established. Those that have been potted off some time, and are established in their pots, should be inured to exposure to the open air, stopping the shoots to keep them dwarf and stocky. *Wistaria sinensis*, *Jasmines*, and the *Virginian Creeper*, may be propagated by cuttings. *China Roses*, *Heartsease*, or the *Tree Violet*, may also be increased now. *Mignonette* for winter and spring flowering may be sown. The work of mowing and general cleaning must be well followed up.

STOVE.

As the nights become cold a little fire heat may be given, not with any intention to promote growth, but to assist in ripening the succulent wood. See that everything is free from insects, and keep the foliage of such things as *Ixoras*, &c., clean by washing with a sponge and soapy water when necessary.

GREENHOUSE AND CONSERVATORY.

Let the stock of *Begonias* have another shift if not already in pots large enough. *Lilium lancifolium* will now be in its beauty. Supply it bountifully with water, and shade the flowers from powerful sunshine to prolong their gaiety. Pay attention to *Chrysanthemums*. They must not be stopped later than this to have fine heads of bloom. A little liquid manure will assist them. Let it be applied twice a-week. *Heliotropes*, *Verbenas*, Scarlet *Pelargoniums*, and *Roses*, required for decorative purposes, should be progressively shifted, stopped, and trained. They will be found useful till a late period of the year. *Cinerarias* and Chinese *Primulas* are common plants which cannot be put aside, and which amply repay attention bestowed on their culture. The earliest-struck *Pelargoniums* should now be potted off and kept close under glass for ten days or a fortnight, and then expose them on all occasions to the weather, except during heavy rains. The older plants first cut back, which have made shoots an inch or two in length, should now be shaken out of their old soil, the roots trimmed, and repotted in smaller pots. If they can be plunged in a slight bottom heat till the roots get a start it will help them. To have a late bloom of *Fuchsias* let a portion of the stock have their young wood cut back about one-half. If these are placed in a little heat they will break again, and go on blooming till Christmas.

PITS AND FRAMES.

Make a sowing of *Nemophila insignis*, *Collinsia bicolor*, *Leptosiphon densiflorus*, and other hardy annuals for next spring. The Intermediate Stocks will require to be pricked out into pans or boxes, and afterwards potted singly in small pots, using good stiff loam; likewise the *Schizanthus* of sorts. Place them in a cool close frame till well established.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

We are still pretty much at a standstill. We had a few slight refreshing showers on Sunday, the 21st, just enough to wash the foliage and damp the surface of the dust-dry earth. We feel sure that our time of visitation will come, and as we can do no better we must patiently wait for it. On the 20th we could see rain falling heavily a few miles distant, and on the 21st, at less than two miles off, we could see it falling copiously, whilst it came to us in drops. We have long noticed that thunder clouds break on our heights and discharge their contents in the surrounding vallies. A scarcity of water in elevated positions does something to counteract the importance of an invigorating atmosphere and extended varied landscapes.

The well that supplies our mansion is nearly 300 feet in depth. From that we quietly for a time borrowed a few pailfuls a-day for syringing purposes, using it after it had stood in the sun. If we take a potful now it is pretty well as good as stealing it, as the place has been put under lock and key. With our limited geological lore we do not think the precaution will avail much, as if not a drop of water was taken from the well, it would, we believe, sink to the same level as the surrounding streams, all of which are several miles distant. We shall be agreeably disappointed if many deep wells do not become dry and require sinking in November and December, and that not so much owing to the drought of summer as to the deficient rainfall in winter and early spring. That deficiency if it occurs will be little influenced by the using or refraining from using the water in such wells now. It is vain to suppose that the water will remain at the same level in the well, because not drawn, just as water in a barrel would do, because the tap from it was keyed up. If there should be a deficiency of water in wells in winter, it is cheering to think that in all probability there will be plenty of surface water.

The parching dryness of the atmosphere has also been a peculiar feature of this summer's drought. On the principle of compensation, it has generally happened, that the drier the weather, the more was the atmosphere charged with vapour, and that vapour, independently of affording relief to the foliage of plants, even by day, was generally precipitated in copious dews in clear, starry nights. We have had, it is true, such refreshing dews, but not at all in proportion to the warmth of the day, and the clearness and cool atmosphere of the night. With a heat during the day little less than that of the tropics, and a coolness at night something in proportion, we have had nothing like their heavy dews, and that solely owing, we believe, to the dryness or deficiency of vapour in the air. This dryness has rendered the air more burning in bright sun, and more chilling in clear nights. After such a bright day as the 24th, and a clear night following, there was but little dew, and that was a crust of hoar frost at 4.30 A.M., and from water we lifted ice, not so thick as a shilling, but thicker than a sixpence. A good number of large corymbs of Scarlet *Geraniums* had their petals whitened and browned as if a hot iron had been placed near them. With all the advantages of drainage to gardens and fields, it may be possible from lessening the surface of evaporation, to render our atmosphere in the southern and eastern counties drier than may be desirable.

There is a little matter here which we would be glad to ventilate. We have a large pond between the garden and the farm, fed by rainfall from some buildings, but chiefly by drainage. For both establishments it was considered a main supply; the water, when pumped into a cistern, being conveyed in pipes to the houses in one case, and to sheds and troughs in the other. That has been quite dry since the beginning of June. It was surrounded, except for a little space at the north end, by trees and bushes, such as *Ash*, *Oak*, *Thorn*, &c., presenting not only a thicket at the sides, but the branches pretty well meeting in the centre of the pool, and affording a thickish shade in the summer months. Partly from the idea that the roots of these trees absorbed and made conduits for the water, and partly from the leaves falling and, in the course of years, tainting the otherwise clear water, it was resolved to cut down most of these trees. Now, allowing that the fallen leaves might be obnoxious when pure water was desirable, our own opinion is, that it was a mistake, so far as keeping water was concerned, to cut down these trees, as we believe that from their arresting evaporation from such a large surface of water they quite made amends for what the roots in the bank might absorb; whilst, by their removal, the whole of the moisture condensed by the foliage was lost. We have stood of a morning and heard a brisk shower of condensed moisture patter into the pool, when all outside was dry. The more pointed the leaves of the trees, so as to become sooner cooled, the more powerfully would they act as condensers of the surrounding vapour. Even in the case of a Beech tree that overhung a road, we recollect noticing, by means of shallow vessels placed below a portion of it, that in one morning it condensed and threw down not less than twelve gallons. The question to be solved, then,

is, whether such reservoirs should be shaded or exposed. As preservers and feeders, we think the trees an advantage rather than otherwise. In an agricultural point of view there can be no question of the improvement of throwing a number of small, crooked, unsightly meadows into one straight-sided field, and thus grubbing up much hedgerow bushes, and timber. This, however, may be carried to such an extent as greatly to lessen the water supply.

One of our chief jobs during the week has been cleaning and greatly enlarging a simple reservoir for surface water when it comes. This simple reservoir is placed among trees at the back of a range of sheds; a wide road separates the sheds from the west garden wall, and inside of the wall are the main houses and Melon ground. The water from the houses goes into a cement-tank, which now contains our only supply, at present just $1\frac{1}{2}$ inch of water, and which we use as carefully as if it were wine. All that falls on the Melon ground, and paths, and spaces between the pits and frames, and also on the glass of most of such pits, and on the roadway, we mean to divert into this simply-made reservoir. When much smaller it did us good service, and if we have such thunder showers and winter rains as we used to have, we know that we shall have it full before spring.

This reservoir dug out of the clay, is, for its main part, $5\frac{1}{2}$ feet deep. It is an oblong square 19 feet by 15 feet at bottom, and 25 feet by 21 feet at top, so as to give a good slope to the banks, the slope being fully 7 feet. In addition to the oblong, for convenience and to lessen the swell of the water against the sides, we have a small neck at the corner 7 feet deep, 4 feet square at bottom, and 8 feet at top, for the pipe of a common iron pump to go in, the pipe being cased in a wooden box pierced with holes to let in water, and keep out mud, of which we believe there will be little. This smaller neck has its sides tarred, and road drift thrown on, and some old slabs placed against the sides, kept in their places by cross pieces jammed in between slab and slab. These were added to secure the banks there, as previous experience told us that with the action of the pump, &c., it was the point where the swell was likely to injure the banks. We have the main banks all beaten smooth and uniform in slope, and to-day we expect to cover them all with a thin layer of tar, on which we will throw as much road drift and sand as it will take in, and then draw a clean spade over it, when it will resemble a well, and besides the digging, the whole expense will be a few shillings. The bottom, by the treading, will be watertight enough, but for neatness and ease of cleaning afterwards, we may also give that a coat of tar, and beat an inch of fine gravel into it. We do not expect ever to have much sediment, unless when there are very heavy thunder showers that will pretty well defy our cesspools.

We have tarred the sides for this reason. Previously the pool held the water well enough when it stood in it some time, but as we drew it out and the sides became exposed, the clay cracked; and then when we had a fresh supply from rain, if enough to raise the water in the reservoir a couple of feet or more, it quickly subsided through these cracks until they were fully swelled up. This was very little lessened even by a covering of turf. A little straw or branches were the best protectives. We have no fear of our tar-covered bank cracking except by frost in winter, and that will be best prevented by hanging some straw over that part not covered by the water. We may mention that the overflow of our cement tank will also find its way to this clay reservoir. In former years this tank overflowed every winter, and we were also forced to make an overflow from the reservoir, but for two years past this tank has never been nearly full.

We do not expect that for six or eight months our reservoir, coated with tar, will furnish water sweet enough for a teakettle, or, perhaps, for some plants extra tender, but for all out-door vegetables and plants in general the slight taint of the tar will be advantageous rather than otherwise.

As to getting the water, if we have anything like an average rainfall, we feel sure from the space at our command that this huge place will be full before spring. The mode of conveying water to the reservoir is as simple as possible. The road in front of the sheds is smooth and hard; and instead of being rounded in the usual way, it slopes a little from east to west, the west side next the sheds terminating in an open drain or culvert—that is, for a space 18 inches

wide the centre may be about 2 inches lower than the rest—quite sufficient to take a great flow of water to a deep cesspool, from the top of which it flows into the reservoir. The water that falls on the Melon ground is intercepted in the same way. The most of the low pits have no spouting, as that is sure to come in the way, but immediately in front the ground has been tarred and sanded, and in some cases the front wall also. The ground between the pits is lowest in the middle; and from thence by slightly hollowed open culverts, so shallow as not to be noticed unless in a heavy rain, the water from a heavy shower is conveyed to several cesspools, from which the contents are taken in one drain across underneath the road. With but little trouble, therefore, a great quantity of water may be secured and stored.

Had we obtained some of those heavy thunder showers that fell within a few miles of us, we would in this clay reservoir have had 2 or 3 feet of water all over, which of itself would have made us independent as to moisture. As it is, all that we have been able to do is to mulch and shade to keep things alive, and having for years rather prided ourselves on fine autumn Peas, we fear that this season we must soon go without. We also fear that we shall have some bolted Celery this year, for even our sewage water has been so scarce that for several weeks the Celery has been left to its fate, merely mulched with tree leaves and shaded a little with branches. As yet, however, it shows no great signs of distress.

We have lifted lots of our pricked-out vegetables, and planted them with balls, just giving each plant a homoeopathic dose. Those planted out early have done well in all the heat, with no help but frequent surface-stirring; and in the case of Cauliflower a little mulching. We shall be obliged to mulch Kidney Beans and Scarlet Runners if we wish to keep them vigorous. Unless the liquid is of an enriching nature, we are sure that much of the slight waterings given by some people does more harm than good. Even when a good watering is given the water should be soft, exposed to the sun previously and warmed, and, if possible, applied at night, or in a cloudy drizzling day. We were lately favoured with an account of a young gardener being next to turned out of his place because he was deemed so thoughtless and inconsiderate as to give a good watering to a very dry flower-bed in a cloudy drizzling day. He ought, instead, to have been commended because he did think; and from thinking made his labour and the water tell in a threefold degree to what they could have done in a clear sunny atmosphere.

As water has been our chief theme, we may as well finish with it as respects the fruit and ornamental garden. For general matters we would refer to our previous gossip for a fortnight. The dry chilly nights have caused us to alter a little our treatment of watering our Strawberry plants in pots. For reasons stated above we have, until lately, watered towards evening, that the roots might get the benefit of the liquid, instead of its being quickly evaporated in the atmosphere. Whilst the chilly nights continue we will prefer watering before breakfast time, that the pots and surface soil may be drier before night, and therefore not be excessively cooled by the combined agencies of radiation and evaporation.

From the flower garden many truths may be learned as respects watering this season. We would especially direct the attention of our young readers to Mr. Robson's article last week, and also to one some time ago in the beginning of summer. We have letters complaining that though water has been used largely, the plants refuse to grow. We have others stating that Geranium-beds, that never had any water since the beginning of June, were never better. We have in previous Numbers endeavoured to explain these anomalies. For ourselves our Geraniums were never better as yet, and after they were pretty well established, they have had no water to speak of since the beginning of June, except two showers, which just cleaned the foliage and swelled the stems. Calceolarias and Verbenas are suffering, and, we believe, even they would not have suffered much had we been able to mulch them more. Verbenas and Dahlias we have been obliged to leave to their fate. Calceolarias, even yet, with no water are very fair. The one that has suffered most, not as to killing it, but as giving us a narrow line of creamy yellow instead of a mass some 18 inches wide, is the

amplexicaulis. In a damp dripping season, it would have been magnificent. As it is, it has given us a line of yellow since the beginning of June. Could we foretell the seasons we might plant better. Calceolarias delighting in moist dripping summers, and Scarlet Geraniums rejoicing in such a season as this, so far as the south is concerned. We do not believe that deluging with water would have improved Scarlets on the whole. No doubt, if soft, warm, and rich, the individual trusses would be finer, but the foliage also would be larger. We observe that, owing to the dryness, the trusses are coming smaller. It is scarcely possible to have all advantages; but we may accommodate ourselves to circumstances if we cannot bend these circumstances to our will.—R. F.

COVENT GARDEN MARKET.—AUGUST 27.

Out-door produce is plentiful, except Cabbages, which the long drought and the recent frost have rendered very scarce. Apples, Pears, and Plums, are coming in large quantities, and Peaches and Nectarines are likewise abundant, though generally not equal in size to those sent in ordinary seasons. Of Grapes and Pine Apples there is a good supply, but Oranges and Lemons are very scarce. Imports from abroad only comprise Green Gage and other Plums, and Pears, the consignments of the latter being heavy, and realising but a low figure. The principal dessert Pears now to be had are Jargonelle, Bon Chrétien, Beurré d'Amansis, and Duchesse d'Angoulême, of which last only a few have as yet made their appearance. Filberts and Walnuts are beginning to arrive in large quantities.

TRADE CATALOGUES RECEIVED.

John Cranston, King's Acre, near Hereford.—Descriptive Catalogue of Selected Roses.

B. S. Williams, Paradise & Victoria Nurseries, Holloway.—General Bulb & Fruit Tree Catalogue.

TO CORRESPONDENTS.

We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

Books (A Constant Subscriber).—The "Fern Manual," which may be had at our office for 5s., or free by post for sixty-four postage stamps. (T. L. K.).—The "Science and Practice of Gardening," which you can have from our office by sending your address and forty postage stamps.

DYING SPECIMEN FERNS (D. N.).—The best paper for the purpose is very thick blotting-paper, which you can obtain of any stationer.

FLOWER GARDEN PLAN (S. B.).—We think your planting would do very well. Did we make a change it would be to transpose the planting of 5, 6, and 7, 8, making 5, 6, Cineraria maritima, and 7 and 8 Stella, and altering the outside ring accordingly. The reason for this would be the having light and dark colours alternately. The main features of the group are similar to those of one given in No. 157 as existing last year at Putteridge, only the inner circle of clumps are more curved, and there are four smaller and four larger clumps in the outside circle. We will mention the planting this year, as it may give you some hints. 17 is tall Geranium in the centre, fringed with Eremocarpus scaber; round the Geranium a fringe of white Pentstemons; then a broad band of light Heliotrope Triomphe de Liège, followed by a ring of Caphea strigillosa; then a band of Lobelia Paxtoni, and the outside like yours; round the dial a band of Cerastium tomentosum. In the first circle of eight clumps, each is centered with a tall dark Fuchsia, with Convolvulus major peeping through them; and four are filled up with scarlet Geraniums—say 1, 2, 5, 6; and four with Calceolarias—say 3, 4, 7, 8. Of the Geraniums, two are Boule de Feu, and two Stella, and the four are edged with Lady Plymouth Geranium. The four Calceolaria-beds consist of yellow Aurantia multiflora, with a dense margin of the dark Victory. The four smaller outside beds, alternating with the four larger ones, are each centered with a Honeysuckle, and Canary Nasturtium running through it. A chain of three links is made in the centre of the bed, a larger link round the Honeysuckle, and a smaller one at each end. The links are formed of Yellow Prince of Orange Calceolaria in one line. Inside, the links are filled with dark Calceolaria, as Crimson King, Victor Emmanuel; outside, with Lobelia speciosa, and a small band of Cerastium next the grass. The large beds have a chain of three equal links along the middle, the chain formed of Bijou Geranium. The centre link is centered with a large old plant of Tom Thumb Geranium, surrounded by Prince of Orange Calceolaria. The two end links have each a white-flowering Fuchsia in the centre, and surrounded with a dense mass of Christine Geranium. Outside the Bijou chain the bed is filled with the lilac Verbena pulchella, which beautifully softens down the whole.

WARD'S CASES (H. Bagge).—We do not know any one who keeps these cases for sale. You can have the Bijou plant case of any size you like, and can obtain particulars from the maker, Mr. Stocks, Cabinet-maker, Archer Street, Notting Hill. They are precisely on the same principle as Ward's cases. The Trichomanes radicans can be grown in a glass pan covered by a well-glass quite as well as in a case.

AMARYLLIS FORMOSISSIMA (*Jacoba* Lily).—We are not aware that this bulbous plant has been proved hardy in this country, and we do not recollect the statement by Mr. Beaton as to its hardiness. It might do planted out in the open borders in April, and would no doubt flower in May or June if the flower-scape had been formed in the previous year; but it is very questionable whether the heat of our short summer would be sufficient to induce and mature a strong growth, so as to keep the plants year after year in a blooming state. It is certainly worth a trial, but we have no experience on the subject. Deep planting of bulbs may protect them from frost, but we do not recommend such treatment, and the Amaryllis family are the last that we should try it with.

CULTURE OF PLANTS (*Ignotus*).—Only the treatment of eight plants asked for at once, any one of which if fully described would occupy at least one page! *Bougainvillea splendens* requires a stove temperature when growing, with that of a greenhouse when at rest, and a dry state of the soil, which should be turfly loam one-half, turfly peat or leaf mould half, with a liberal admixture of sand. *Medinilla magnifica*, a stove plant, requires a compost of turfly sandy peat two-thirds, turfly loam one-third, with a free admixture of silver sand. It blooms in May or June, and should then be repotted and cut back if necessary, but both operations should not be performed at the same time. Cut back after flowering, and pot when the shoots have pushed an inch or two. *Campylobotrys refulgens* needs a warm close stove, a compost of sandy turfly peat with a little loam and sand, abundant drainage, and slight watering, with a moist atmosphere, but no syringing overhead. *Hibiscus Cooperi*; soil, loam two-thirds, leaf mould one-third, with a little sand incorporated with it, and the temperature of a stove. *Eriocnema marmorea*, the same treatment as for *Campylobotrys*. *Cissus porphyrophyllus*, a stove climber, requires slight shade, abundant space, and a soil composed of peat two-thirds, loam one-third, with a little sand. *Miconia pulverulenta*, a new plant, succeeds in a compost of peat and turfly loam in equal parts, with about one-sixth of sand added. It, too, is a stove plant, and a fine one, impatient, as all plants with fine foliage are, of much syringing. *Aglaoisma commutatum*, is another of the fine-foliated plants that are all the rage just now. It is a stove plant, requiring a compost of turfly peat two-thirds, loam one-third, with a free admixture of sand, abundant drainage, a moist atmosphere, and copious waterings when growing vigorously, but about half the quantity at other times.

SEEDLING ROSE (J. Cranston).—We regret that we did not see your Rose "King's Acre" in the season, for when such beautiful flowers are produced now, after such a drought, we may well ask what must it have been then? Those you sent were very fine, globular, and of a colour much wanted—purplish rose, with the reverse of the petals light. It is a really fine flower; and if, as you say, vigorous, having withstood the season of 1860 as a seedling, it will be a valuable acquisition to our English-raised Roses.

IVY DETACHED FROM A WALL (*Old Deer*).—We advise you to try and fasten the Ivy to the wall with iron holdfasts, and if this can be done without breaking the main branches it may be allowed to remain over the winter, and then be cut in the April of the following year; but if that be impracticable we think you would do well to cut away all the stubborn branches that cannot be fastened to the wall, and to train in the weaker or smaller ones. We should do it forthwith on the score of neatness; but if you do not mind the appearance you may train the small branches to the wall now, and defer cutting away those which are strong until March, when, on their removal, a large amount of nutrient will be thrown into the small branches, which will cause them to become exceedingly vigorous in the following summer.

VINE SHOOTS DISEASED (G. E. T.).—We never saw any so badly galled. The roots we think must have descended into an ungenial subsoil. If so, the only remedy will be to lift them to within 18 inches of the surface, and to tempt them to remain there by keeping the surface mulched in summer with long stable manure. The Fern you enclosed is *Nephrolepis pectinata*.

NAME OF INSECT (J. W. Anfield).—The insect was too crushed to be certain, but we think it is only what is usually called "the Harvest Bug."

FUCHSIA FLOWER-BUDS FALLING (A Lincoln Lady).—We think the buds fall owing to the dryness of the atmosphere and defective root-action. Perhaps you have the pots standing in saucers, and the plants are thus deluged with water, causing the young fibres to rot, and it being these that feed the buds, the latter fall for lack of nourishment. Placing the plants out of doors at night will conduce to their healthy growth; but we think that alternate changes of cold and heat are not proper for a plant in a flowering state. The extreme dryness of the room, and the sudden change to the open air, are a probable cause of the falling of the buds. The plants cannot be too near the glass, but with the hot weather we have had recently it is likely that the evaporation from the leaves would be more than the supply from the roots, and the buds would then fall. The falling may have been caused by a dry state of soil, even if but for a few hours, or by the want of fresh air. The remedy will be the opposite course of treatment. (*A Perplexed Subscriber*).—From your description of the treatment there is nothing, so far as we can discover, that could affect their blooming, except it be an insufficiency of water at the root. Water every two days is too little. Ours have required watering at least once a day, and even that has been scarcely sufficient to keep them from flagging. Too much or too little water are equally injurious, and not less so is a dry atmosphere accompanied by a high temperature, and insufficient ventilation. You may enjoy the luxury of eating Grapes of your own growing by planting a couple of Vines if the tree on the south-west does not overshadow the house too much. You will not have room for more than two, and these we would have Black Hamburg; but if you wish for a White Grape, a Buckland Sweetwater may be substituted for one of the Hamburgs. In addition to the Vines, you may have a few plants, as Fuchsias, Geraniums, Primulas, Cinerarias, bulbs, and other greenhouse plants which may be placed outdoors in summer, and the house kept gay with Balsams, Celosias, Amaranthus, and a few Achimenes and Gloxinias.

COMMENCING A MARKET GARDEN (L. R.).—We fear we cannot conscientiously advise you to embark extensively in market gardening without more experience than you probably possess. If, therefore, your field be a meadow let it remain so until you can see more. You will easily find a tenant for it; and if you were to spend a year amongst the market gardens around London, you would obtain more knowledge of the subject than you could from a whole Number of our periodical, that is if you kept a sharp look out and noted everything that was going on around you. If you were determined to start at once, we would say, Begin with part of your land, say one acre, which is sufficient if you crop it with a variety of vegetables, and do all the work yourself. If you determine on this commence at once, and trench a part of it to plant with Cabbage for early spring use. The plants you must buy from some one having a good early sort, as the Enfield Market, Fulham, or Downham. During the autumn and winter you might keep on trenching, and early in spring various crops might be put in, as to which we will give you advice in future Numbers. You must bear in mind that you will have nothing to sell until the end of April or May, when your Cabbages will be ready for market. During the autumn many crops may be got in, as patches of herbs, if they be wanted. Currant, Gooseberry, and other fruit trees may be planted, and in the spring Asparagus, as also Sea-kale and Globe Artichokes, if you intend to cultivate them. We would strongly advise you to find out the wants of the district you live in, and only plant what is likely to sell; of course, when you can see a prospect of a demand for another article then by all means produce it, and be sure and grow everything well, so as to acquire a good name at first, and then we have no doubt you will succeed.

EVERGREENS ON CHALK SOIL (A Constant Reader).—Besides the Yew and Box which you mention, we have planted, and found to flourish, on a similar soil near Winchester—*Laurustinus*, all the evergreen Berberries, Portuguese Laurel, Evergreen Oak, and *Taxodium sempervirens*. The common Laurel and Rhododendrons will not succeed.

RED SPIDER ON FUCHSIAS (J. S.).—Take the plants out of the house or the insects will proceed to the other plants. Syringe them with Gishurst compound according to the directions given on the packet, and repeat the application until the insects cease to appear. Keep the air in the green-house more moist by watering the path.

NAMES OF PLANTS (L. B.).—We cannot undertake to name plants from single leaves. Your tree may be any one of some half-dozen or more with similar leaves that we know. (*Conway*).—*Linaria vulgaris*. (*A Subscriber, Herts*).—1, *Bromus macrostachyus*; 2, unnameable; 3, *Briza maxima*; 4, *Hordeum jubatum*; 5, *Pennisetum villosum*. (*D., Budleigh Salterton*).—Your plant is rightly named. It flowers in winter, when the branches are naked, and is a very acceptable addition to our few indigenous winter flowers. (*E. F.*).—*Cephalandra quinqueloba*. (*Constant Reader*).—*Gaultheria Shallon*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE AGRICULTURAL HALL POULTRY SHOW AND THE POULTRY CLUB.

MR. TUDMAN in reply to my last communication declined to answer publicly any queries put to him, but promised all the information he could give to parties communicating directly with him. Mr. Manning states that he "wrote to Mr. Tudman, asking him for the rules and regulations of the Poultry Club, with the view of becoming a member," and that the answer he received was "to the effect that the rules and regulations were available to members only." The answers to his other inquiries appear also to have been as little satisfactory, as he seems to have relinquished all ideas of membership.

A similar incident occurred to me some time since. The Club had advertised their rules to non-members at 5s. per copy, and I ordered a copy, enclosing a money order for the amount. The rules were, however, notwithstanding refused,

and the money order returned. Mr. Hughes naïvely suggests that parties desiring to have information may obtain it by paying their half guinea and becoming members, which will also put them in possession of the rules; but this savours so much of the showman, that it is difficult to believe the suggestion to have been seriously made, especially, too, as another correspondent, who wrote to Mr. Tudman, states that from his reply it appeared to him doubtful if they deserved any more members.

This, however, is not all. Another correspondent, "*A POULTRY FANCIER*," gravely assures your readers that the rules have not yet been fully compiled, and that they are nevertheless undergoing revision. This would indicate the whole affair to be a new version of the "mountain in labour," in that, after all the pangs of parturition, it has not even given birth to the "*ridiculus mus!*"

But, seriously, who can have confidence in a club under such management? Here is a code of rules promised which were to reduce poultry judging to the precision of a mathematical problem—next they are advertised for sale, but refused to persons applying for them—then the public are informed that they are to be obtained only by those who become members; and lastly, that they are not yet wholly compiled, and are nevertheless undergoing revision! And, to render the state of things more anomalous, with some rules and regulations which appeared in another Journal, Rule 10 states "that the code of rules for the guidance of judges, when made, to be published;" whilst Rule 13 requires "the judges to judge according to the rules drawn up for their guidance." So we are on the eve of a show to be held under the auspices of the Club, where the prizes are to be awarded according to rules not yet compiled. I am aware that this has been virtually denied, and that it has been asserted that the "members of the Poultry Club are not responsible for the prize lists or the getting up of shows." If this is the case the wider it is known the better, that exhibitors may not be misled by the attractive heading of the forthcoming Islington Show—"Under the patronage and management of the Poultry Club."

It is also generally understood that the Islington Committee, when applied to, declined to undertake the responsibility of the Show, having lost £400 by a previous one, and that a few of the Stewards of the Club entered into a guarantee to secure the Committee from loss.

It is time, too, that the public should know who are to be the judges; but this is another of those vexed questions, which appear to have made the confusion of affairs worse confounded. First we are informed that Mr. Hewitt is appointed; but this is now denied, notwithstanding the admission of Mr. Tudman in his letter which appeared in your impression of the 12th of July, in which he says, "Wishing to secure the services of such an upright Judge as Mr. Hewitt, I was anxious to make any sacrifice to meet his views, and the offer to waive the rules was merely a tribute to the great ability and acknowledged experience of the greatest poultry Judge in the world." In his letter to Mr. Hewitt, he says, "All I now simply ask is, Will you act as Judge for us? A large show is about to take place under the management of the Poultry Club, and we trust you will give us the benefit of your acknowledged ability." If this does not amount to an admission of Mr. Hewitt having been engaged it is difficult to find terms more express. But here is the rub—the rules, which form the backbone of the scheme, had to be relinquished ere the services of this distinguished Judge could be secured; and if Mr. Hewitt is not still under engagement, it is through the publicity of this correspondence. Nor are there any judges yet engaged, notwithstanding the contrary has been stated. Messrs. Challoner and Teebay may have been selected, but they are not yet engaged.

Under all those conflicting circumstances the prospects of the impending show (and indeed of any future show under the patronage of the Club), are anything but satisfactory; and what security can exhibitors feel under an Association which, under such circumstances, holds itself irresponsible? With all the secrecy and mystery surrounding its doings, what guarantee have exhibitors that there may not be "ear-wigging" going on within its circle? That there may be "ear-wigging" elsewhere, as Mr. Tudman complains, is not to be wondered at under the circumstances. Mr. Tudman may have in his own estimation chosen the better part of

valour, but if he wishes the Club to succeed it must be by different measures than those hitherto adopted.—AN EXHIBITOR.

YOUR correspondent Mr. Thomas Hughes, a member of the Poultry Club, objects to non-members of the Club being supplied with rules for which he has "had to pay."

He says, surely I "could afford half a guinea," and have had all the information I desired. I do not understand Mr. Hughes. If he means that the rules of the Poultry Club form a little book for which he has had to pay half a guinea, I must tell him I think it is very dear. If he intends to say that any person becomes a member of the Poultry Club who has had to pay half a guinea, I will tell him that this is very cheap, and that therefore I cannot possibly afford to become a member.

I will not judge the Club by the letter of one of its members, but I will wait for the promised information which is to appear in one of the public prints, and then see if I can afford half a guinea.—GEORGE MANNING.

CRAMP IN CHICKENS.

I SHOULD be much obliged if you would explain the cause and prescribe the treatment of a disease by which I have lost several prize Hamburgh chickens this season. The disease first attacks the wings, which become disordered as if from fighting. In three or four days they drop, sometimes one, sometimes both, in such a manner as to impede walking. Then the feet become cramped, and the toes drawn up together as if the sinews of the legs contracted. This rapidly grows worse, and in the course of eight or ten days from the commencement of the attack, the fowl is on its back and quite helpless, and in two or three days more dies. The appetite is good to the last, and in all other respects the fowls appear perfectly healthy. The disease appears when the chickens are about four months old.—RHEUMATISM.

[Your Hamburgh chickens suffer from cramp and die of it. We should expect to find your poultry-house with a stone, brick, or boarded floor—either would cause it. Should such be the case, remove it, or if you object greatly to that, cover it 6 inches deep with dry gravel. It is, however, better to remove it. If this is not the cause, you will find it is some damp spot or place they use, or else poor or insufficient food. Get some ground oats, feed on them morning and midday, and in the evening give bread and ale. This will only be necessary while they are sickly. See that they roost in a dry place.]

SULTAN FOWLS.

I NOTICE in your reply to your correspondent "IGNORAMUS" that you express a doubt as to the existence of Sultans as a pure breed. For the information of your subscriber I write to say that the original imported pen was sold to a gentleman and well-known breeder in Yorkshire, whose entire stock I recently purchased, including the first, second, and third generations from the imported pen, and I trust at some of the forthcoming chicken shows to vindicate the existence of this beautiful breed in its purity.—F. W. ZUHROEST.

ROCHDALE EXHIBITION OF POULTRY.

THIS Exhibition was held on the 24th inst., and, undoubtedly, the grounds of A. H. Rhoads, Esq. afford one of the most beautiful of sites for the purposes of such a Society. The weather, too, was of the brightest character, and the Show was numerously attended by those near at hand; we also observed on the ground a considerable number of gentry from rather distant localities. The efforts of the Committee to display the poultry to the best possible advantage were admitted by every one; and the entries being considerable as to numbers, the only drawback arose from the generality of the specimens exhibited being in the very midst of moult, so that particular details of the birds in their present condition would be unadvisable, even were the attempt carried out. Suffice it to say that, as will be seen

by reference to the prize list, a great majority of our principal poultry-breeders were represented by specimens that in a month or six weeks hence will most probably be in as perfect feather as could be desired. We cannot help, however, calling attention this year to the great deficiency of really early-hatched chickens.

SPANISH.—First, Miss E. Beldon, Bradford. Second, S. Handley, Darlington Cottage, Pendleton. Commended, S. Haslam, Belfield, near Rochdale. **Chickens.**—First, S. Robson, South Milford. Second, J. Stott, Healey, near Rochdale.

COCIN-CHINA.—First, E. Smith, Middleton. Second, Miss E. Beldon, Bradford. **Chickens.**—First, Captain H. Heaton, Lower Broughton. Second, G. Wheeler, Middleton. Commended, Miss E. Beldon.

HAMBURGH (Golden-spangled).—First, W. Travis, Little Moss, Ashton-under-Lyne. Second, Miss E. Beldon. Commended, J. Andrews, Waterhouse, Ashton. **Chickens.**—First, J. Roe, Hadfield, near Manchester. Second, F. Greenwood, Rochdale.

HAMBURGH (Silver-spangled).—First, Miss E. Beldon, Bradford. Second, J. Andrews, Waterhouse, Ashton. **Chickens.**—First, Miss E. Beldon. Second, E. Collinge, Boarshaw Clough, Middleton. Commended, R. Kay, Middleton; J. Fielding, Newchurch.

HAMBURGH (Black).—First, C. W. Brierley, Rhodes House, Middleton. Second, Miss E. Beldon, Bradford. **Chickens.**—First, R. Battersby, Heywood. Second, J. Andrews, Waterhouse, Ashton.

HAMBURGH (Golden-pencilled).—First and Second, S. Smith, Northowram, near Halifax. **Chickens.**—First, J. Fielding, Newchurch, Rossendale. Second, T. Wrigley, jun., Tonge, Middleton. Highly Commended, W. Kershaw, Heywood. Commended, J. Turner, Stand Lane, Radcliffe.

HAMBURGH (Silver-pencilled).—First, Miss E. Beldon, Bradford. Second, C. Boyd, Green Hill, Rochdale. **Chickens.**—First, Miss E. Beldon. Second, J. Platt, Dean, near Bolton. Highly Commended, W. Yates, Unsworth, Bury; J. Sheppard, Ridings, near Rochdale.

POLAND.—First, Miss E. Beldon, Bradford. Second, W. R. Duxbury, Primrose Road, Leeds. **Chickens.**—Prize, Miss E. Beldon.

BRAMHA POOTRA.—First, E. Leech, Greave, Rochdale. Second, H. Lacy, Hebden Bridge. **Chickens.**—First, T. Statter, Stand, Manchester. Second, H. Lacy.

DORKING.—First, T. Statter, Stand, Manchester. Second, E. Smith, Middleton. **Chickens.**—First, E. Smith, Middleton. Secnd, T. Statter.

GAME (Any colour).—First, T. Statter, Stand, Manchester. Second, C. W. Brierley, Rhodes House, Middleton. **Chickens.**—First, S. Cryer, Longclough, Littleborough. Second, J. Turner, Stand Lane, Radcliffe. Highly Commended, F. Bright, Cronkeyshaw, Rochdale; R. Rawstron, North Terrace.

ANY VARIETY.—First, W. Fairburn, Wardle, near Rochdale. Second, Mrs. Crossley, Underwood Yard, Bury Road. Commended, R. Leech, jun., Greave, Rochdale.

GAME COCK.—First, Miss E. Beldon, Bradford. Second, T. Stratton, Stand Hill. Highly Commended, J. Turner, Rochdale; C. W. Brierley, Rhodes House, Middleton.

BANTAM (Any variety).—First, J. W. Morris, Rochdale. Second, Miss E. Beldon. Highly Commended, C. Walker, Bradford.

GEES.—First, W. Kershaw, Heywood. Second, E. Leech, Greave, Rochdale. Highly Commended, W. R. Duxbury, Primrose Road, Leeds.

DUCKS (Aylesbury).—First and Second, E. Leech, Greave, Rochdale.

DUCKS (Rouen).—First and Second, T. Statter, Stand, Manchester. Commended, E. Leech, Greave, Rochdale.

TURKEYS.—First, C. W. Brierley, Rhodes House, Middleton. Second, E. Leech, Greave, Rochdale.

The Judges were Mr. Thomas Chaloner, of Worksop, near Chesterfield; and Mr. Edward Hewitt, of Sparkbrook, near Birmingham.

COTTINGHAM POULTRY SHOW.

THE annual Show of Poultry and Pigeons was held on the 17th instant, and many excellent specimens were shown in almost all the classes. Subjoined is the best prize list we could obtain, as unfortunately there were no printed catalogues, and it was no easy matter for the reporters to get a correct list.

SPANISH.—First, W. Cannan, Bradford. Second, S. Robson, Brotherton. **Chickens.**—First, A. Holmes, Horham. Second, G. Robson, Hull.

DORKINGS.—First, F. Key, Beverley. Second, W. Watson, Bishop Burton. **Chickens.**—First and Second, W. Watson.

COCHINS.—First, E. C. Frotter, Sutton. Second, R. Loft, Woodmansey. **Chickens.**—First, H. Adams. Second, R. Burgess.

GAME (Any other variety).—First, H. Adams. Second, R. Robson, Beverley. **Chickens.**—First, J. Hodgkinson, Hull. Second, H. Adams.

POLANDS.—First, W. Cannan. Second, J. Stephenson, Preston. **Chickens.**—First, J. M. Proctor, Hull. Second, W. Cannan.

HAMBOURGS (Golden-spangled).—First, G. Holmes, Driffield. Second, S. Campling, Cottenham. **Chickens.**—First, G. Holmes. Second, W. Cannan.

HAMBOURGS (Silver-spangled).—First, S. Campling. Second, W. Cannan. **Chickens.**—First, S. Campling. Second, W. Cannan.

HAMBOURGS (Golden-pencilled).—First, S. Campling. Second, W. Cannan. **Chickens.**—First, S. Campling. Second, W. Cannan.

HAMBOURGS (Silver-pencilled).—First, S. Campling. Second, W. Cannan. **Chickens.**—First, S. Campling. Second, W. Cannan.

BANTAMS (Gold-laced).—First, J. R. Jessop, Hull. Second, R. M. Stark, Hull. **Chickens.**—Prize, R. M. Stark.

BANTAMS (Silver-laced, Judge's Prize).—Prize, W. Cannan.

BANTAMS (Game).—First, R. M. Stark. Second, G. Holmes.

BANTAMS (Any other variety).—First, W. Cannan (Black). Second, R. M. Stark (Silver-laced). **Chickens.**—First, J. Gawan. Second, J. Brittain.

ANY OTHER DISTINCT VARIETY.—First, R. Loft. Second, W. Cannan. **Chickens.**—First, O. A. Young, Driffield. Second, J. Pares, Chertsey. **FARMYARD CROSS.**—First, T. Coverdale. Second, R. Loft. **Chickens.**—First and Second, G. Bromley, Cottingham. **SELLING CLASSE.**—First, H. Burstall, Nottingham. Second, G. Bromley. **PEA FOWLS.**—First, J. Ringrose, Cottingham. Second, B. Haworth, Hull Bank House. **GUINEA FOWLS.**—First and Second, O. A. Young. **TURKEYS.**—First, W. Cannan. Second, W. Wallace. **GEES.**—First, O. A. Young. Second, Mrs. Nicholson. **DUCKS (Aylesbury).**—First, O. A. Young. Second, T. C. Trotter. **DUCKS (Rouen).**—First and Second, O. A. Young. **DUCKS (Any other variety).**—First and Second, J. R. Jessop (East Indian and Wild). **PIGEONS.**—*Croppers.*—First, S. Robson. Second, W. Watson, Beverley. *Carrions.*—First, G. Robson. Second, H. Yardley, Birmingham. *Turbits.*—First, H. Yardley. Second, J. R. Jessop. *Trumpeters.*—First, F. Key. Second, W. B. Van Haasbergen, Newcastle. *Jacobs.*—First, J. W. Edge, Birmingham. Second, T. Ellington, Woodmansey. *Fantails.*—First, T. Ellington. Second, J. R. Jessop. *Dragoons.*—First, W. Watson. Second, T. Statters, Hull. *Tumblers.*—First, W. B. Van Haasbergen. Second, W. Watson. *Barbs.*—First, W. B. Van Haasbergen. Second, H. Yardley. *Nuns.*—First, F. Key. Second, W. Watson. *Any other variety.*—First, S. Robson (Runts). Second, G. Robson (Spots). *Tumblers (Blue Baldpate).*—Extra Prize (Given by Mr. W. A. Summers), J. W. Edge. The liberal prizes offered by this gentleman for Nuns with the usual colours reversed failed to bring a single entry, and neither Red-headed nor Yellow-headed Nuns put in an appearance, although we understand the two latter are to be seen in the neighbourhood.

F. Ferguson, Esq., was the Judge.

TONG POULTRY SHOW.

THE fourth annual Exhibition of the Tong Poultry Society took place at Dudley Hill, on the 16th inst. The entries were much more numerous than in previous years, and the poultry throughout were very good, and so were the Pigeons.

The following is the prize list:—

SPANISH (Black).—First and Second, Miss E. Beldon, Gilstead. **DORKINGS.**—First and Second, Miss E. Beldon. **COCHIN-CHINA.**—First and Second, Miss E. Beldon. **GAME.**—Prize, T. Suddick, Tong Street. **HAMBURGH (Black).**—Prize, Miss E. Beldon. **HAMBURGH (Golden-spangled).**—First, J. Greenwood, Cutler Heights. Second, Miss E. Beldon. **HAMBURGH (Silver-spangled).**—First and Second, Miss E. Beldon. **HAMBURGH (Golden-pencilled).**—First and Second, Miss E. Beldon. Highly Commended, J. Gans. **HAMBURGH (Silver-pencilled).**—First and Second, Miss E. Beldon. Highly Commended, H. Firth, Tong Street. **POLAND.**—First and Second, Miss E. Beldon. **BANTAMS (Game).**—First, Miss E. Beldon. Second, H. Firth. **BANTAMS (Any other variety).**—First and Second, Miss E. Beldon. Highly Commended and Commended, S. Rhodes. **SINGLE COCK (Any variety).**—First, Miss E. Beldon (Cochin). Second, T. Suddick (Game). **DUCKS (Rouen).**—Prize, Miss E. Beldon. **DUCKS (Aylesbury).**—First, J. Blackburn. Second, C. Holmes. **GEES.**—First and Second, G. Yates, Holm Lane. **PIGEONS.**—*Pouters.*—Prize, Miss E. Beldon. *Carriers.*—Prize, Miss E. Beldon. *Trumpeters.*—Prize, Miss E. Beldon. *Owls.*—First, Miss E. Beldon. Second, A. Field, Dudley Hill. *Barbs.*—Prize, Miss E. Beldon. *Jacobs.*—Prize, Miss E. Beldon. *Tumblers.*—First, Miss E. Beldon. Second, A. Field. *Tumblers (Almond).*—Prize and Commended, A. Field. *Antwerps.*—First and Second, A. Field. Highly Commended, A. Field.

The Judges were Mr. E. Hutton, Pudsey, Leeds; and Mr. L. Bedom, Gillington, Bradford.

SCARBOROUGH AND HACKNESS AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE Poultry Show in connection with this Society took place on the 19th inst., and the Scarborough Song Bird Society's Exhibition was held at the same time.

The following is a list of the prizes awarded:—

SPANISH.—First, W. Cannan, Bradford. Second, W. K. Duxbury, Leeds. **Chickens.**—Prize, W. Cannan. **DORKINS.**—First, J. Key, Leeds. Second, O. A. Young, Driffield. **Chickens.**—Prize, J. Key, Beverley. **COCHIN-CHINA.**—First, T. H. Barker, Hovingham. Second, O. A. Young, Driffield. **Chickens.**—Prize, T. H. Barker. Highly Commended, W. Cannan, Bradford. **GAME.**—First, R. Hardy, Ruston. Second, G. Cartwright, Seamer Lane. **Chickens.**—Prize, R. Hardy. **HAMBURGH (Golden-spangled).**—First, Mrs. T. Darrel, Ayton. Second, J. Atkinson, East Ayton. Highly Commended, R. Smith, Norton, Malton. **HAMBURGH (Silver-spangled).**—First, W. Cannan, Bradford. Second, J. Atkinson, East Ayton. **HAMBURGH (Golden-pencilled).**—First, A. Hawe, Burniston. Second, W. Cannan, Bradford. Highly Commended, O. A. Young, Driffield. **HAMBURGH (Silver-pencilled).**—First, J. Eilton, Cottingham. Second, W. Cannan, Bradford. **POLAND.**—First, W. Cannan, Bradford. Second, W. K. Duxbury, Leeds. Highly Commended, Messrs. Haynes & Hough, Bedale. **ANY DISTINCT BREED NOT PREVIOUSLY MENTIONED.**—First, O. A. Young, Driffield. Second, W. Cannan, Bradford. **Chickens.**—First, W. Cannan, Bradford. Highly Commended, R. E. Turnbull, Hackness.

BANTAMS (Black or White).—First, R. Smith, Norton, Malton. Second, Lady Londesborough. **BANTAMS (Neither Black nor White).**—First, G. Holmes, Driffield. Second, W. Cannan, Bradford. Highly Commended, O. A. Young.

GEES.—First, O. A. Young, Driffield. Second, W. Duxbury, Leeds. **Goslings.**—Prize, Mrs. Hopper, Wykeham, Grange.

DUCKS (Aylesbury).—Prize, O. A. Young, Driffield. **Ducklings.**—Prize, Mrs. G. P. Dale, Scarborough. **DUCKS (Rouen or any other Breed not Aylesbury).**—First, T. H. Barker, Hovingham. Second, J. Brain, Pickering. **Ducklings.**—Prize, Mrs. J. Darrell, Ayton.

TURKEYS.—Prize, W. Cannan, Bradford. **Poults.**—Prize, O. A. Young, Driffield.

GUINEA FOWL.—First, O. A. Young, Driffield. Second, J. Riby, Ruston.

PIGKINS.—*Croppers.*—Prize, J. R. Trennan, Helmsley. *Carriers.*—Prize, J. Dotchen, Whitby. *Trumpeters.*—Prize, J. Key, Beverley. *Fantails.*—Prize, R. Esh, Helpethorpe. *Tumblers.*—Prize, J. Dotchen, Whitby. *Barbs.*—Prize, J. Dotchen, Whitby. *Any other Variety.*—Prize, J. Hodgson. *Ornamental Waterfowl.*—Prize, Mrs. G. P. Dale Scarborough.

RABBITS (Any Breed).—Prize, W. Holmes, Driffield. Highly Commended, J. Grimshaw, Bridlington.

SONG BIRDS.—*Canary (Half-bred).*—First, R. Cross, New Queen Street.

Second, J. Oxley, Alma Parade. *Canary (Common).*—First, W. Bean, William Street. Second, R. Cross. *Canary (Marked).*—First, R. Cross. Second, J. Rainton, Dumble Street. *Canary (Crested).*—First, J. Rainton. Second, J. Oxley. *Canary (Cinnamon).*—Prize, J. Oxley. *Lizard (Golden or Silver-spangled).*—Prize, J. Oxley. *Mule (Marked).*—Prize, W. Bean. *Mule (Orange).*—Prize, R. Cross. *Best Cage of Birds.*—First, R. Cross. Second, J. Oxley.

SWEEPSTAKES.—*Canary (Yellow Belgian).*—First, W. Hogg. Second, W. Jefferson, Knapton Station. *Canary (Buff Belgian).*—Prize, W. Hogg. *Canary (Half-bred).*—Prize, W. Jefferson. *Canary (Buff Half-bred).*—First, W. Hogg. Second, J. Towell, St. Sepulchre Street. *Canary (Yellow Norwich).*—First, C. Yeoman, Long Westgate. Second, S. Smith, Falconer Square. *Canary (Common Yellow).*—First, W. Jefferson. Second, E. S. Midgley, South Cliff. *Canary (Common Buff).*—First, W. Jefferson. Second, E. S. Midgley. *Canary (Marked).*—Prize, C. Leader, St. Thomas Street. *Mule (Marked).*—First, W. Hogg. Second, W. Jefferson. *Mule (Orange).*—First, W. Wood, St. Nicholas Street. Second, J. Hattersley, Seamer Lane. *Parrot.*—First, R. Oxley. Second, D. Wright.

The Judges for Poultry were Mr. George S. Simpson, North Burton; and Mr. Richard Nesfield, Snainton.

OWSTON, ISLE OF AXHOLME, POULTRY SHOW.

THE Owston Poultry Association celebrated its anniversary on the 10th inst., and notwithstanding numerous drawbacks the Society continues to increase in usefulness and prosperity. The Judge, Mr. J. Hodgkinson, of Hull, who has officiated at this Show previously more than once, spoke highly of the improvement to be noticed in the several classes exhibited; and to show that his efforts had been appreciated elsewhere, he was, on the preceding evening, presented with a valuable gold watch and chain by the Cottingham Floral, Horticultural, and Poultry Association. He pronounced this show of poultry, &c., an excellent one, particularly noticing three pens of chickens shown by Mr. F. Sales, of Crowle—viz., Brown Red, Black Red, and Grey Game, and awarded each pen a prize as extra stock. Several specimens of English and foreign birds shown by Mr. G. E. Addey, of Epworth, elicited great admiration, and were awarded a premium. Although the number of pens was not so great the quality of the birds was superior to former exhibitions, and evinced the care in the breeding.

The following is a list of the awards:—

DORKINGS.—Prize, F. Sales.

POLANDS.—Prize, F. Sales.

GAME.—Prize, F. Sales.

BANTAMS.—Prize, W. Benson, Clarborough.

HAMBURGH.—Prize, E. Barrow, Ferry.

TURKEYS.—Prize, F. Sales, Crowle.

GEES.—Prize, Mrs. Dixon, Mellwood,

DUCKS.—Prize, Bealley, Kelfield.

GUINEA FOWLS.—Prize, F. Sales, Crowle.

DOMINIQUE FOWLS.

Not being a regular reader of the Journal I am not aware whether you have given any account of the Dominique fowl previous to that published in the Number for July 12th, and I therefore send an extract from the *American Agriculturist*, containing an account of that variety.—F. H.

"This well-known and much-neglected common fowl is supposed to be an old and distinct variety, though usually looked upon as a mere farm-yard fowl—that is, the accidental result of promiscuous crossing; but there are several forms among the barn-yard fowls, so called, that are seen to be repeated generation after generation, the counterparts of which are met with scattered here and there all over the

country. The Dominiques are distinguished by their markings and their colour, which is generally considered an indication of hardihood and fecundity. By some they are called 'Hawk-coloured fowls,' from their strong resemblance in colour to the birds of that name. In England they are usually called 'Cuckoo fowls,' from the fancied resemblance of their plumage to the feathers of the Cuckoo's breast.

"The prevailing and true colour of the Dominique fowl is a lightish ground, barred crosswise, and softly shaded with a dark slate blue. The combs vary, some being single, while others are double—most, however, are single. Feet and legs light flesh colour and yellow; bill the same as that of the legs.

"The merits of this breed recommend them to persons residing in the country, as well worthy of promotion in the poultry-yard. Whether as makers of eggs, or of meat, as sitters, or as nurses, they are valuable. We seldom see bad fowls of this variety; and, take them all in all, the writer does not hesitate in pronouncing them one of the best and most profitable, being hardy, good layers of more than medium-sized eggs, steady sitters, careful nurses; and, what is very important, the chicks are hardy, feather early, and are easy to rear. It is a perfect vexation to try to raise chicks of some of the more tender varieties, for they are continually drooping and dying. The Dominiques afford excellent quality of eggs, and flesh of a juicy, high-flavoured character—in the latter quality little inferior to the Dorking.—C. N. BEMENT."

[From this description we infer that the Dominique is only a Cuckoo Dorking, probably without the characteristic Dorking claw.]

A KNOTTY QUESTION.

At the Woodbridge County Court, on the 15th inst., an action was brought by H. Payne, of Stowmarket, solicitor's clerk, against John Dallenger and Frederick Whisstock, Secretaries of the Suffolk Poultry Society, Woodbridge, to recover the sum of 8s., under the following circumstances:—The defendants were the Secretaries of the Suffolk Poultry Society. On the 7th of May, 1864, the plaintiff entered a Dorking cockerel to be exhibited in a sweepstakes at a Show to be held at Woodbridge on the 26th and 27th of May, 1864, and paid to the defendants an entrance fee of 7s. 6d. No other entry was made for the sweepstakes, and the defendants neglected to inform the plaintiff thereof, whereby he incurred an expense of 3s. for carriage in sending his (plaintiff's) cockerel to and from the said Show; and the defendants retained 5s., part of the entrance fee. The plaintiff contended that one entry did not constitute a sweepstakes, and that, therefore, the defendants ought to have written to him, stating that fact. Mr. Dallenger, one of the defendants, pleaded the rules of the Society and the form of the entry paper as signed by the defendant, contending that the entry of the bird was for exhibition, not competition only, subject to the rules and regulations of the Society; that he was not bound to inform the plaintiff that there was only one entry, but that if he had done so he would have been guilty of a breach of trust, his duty being to take care of the interests of the Society. He contended that, under Rule 10, persons entering poultry, and failing to send it, forfeit the entry fees, and that they were entitled by the sweepstakes rule to deduct 5s. from the entry. His Honour said he saw no rule requiring the Secretaries to inform exhibitors when there was only one entry, and eventually deferred his judgment till the next court.—(*Essex Gazette.*)

PIGEONS AT NEWCASTLE-UPON-TYNE AND DARLINGTON SHOWS.

It appears from Mr. Shorthose's letter in your impression of last week, explanatory of his appointment of the Pigeon Judge at Newcastle-upon-Tyne, he concluded, "That if Mr. Botcherby was competent to judge at an important Show like that at Darlington," he could not do wrong in obtaining Mr. Botcherby's services, although as to his competency for such a task he "knew but little."

Doubtless, Mr. Shorthose did his best under the circum-

stances; but it is the misfortune of exhibitors that so little was known, and so little cared for the mistake in the Darlington appointment, thus entailing a like dissatisfaction at Newcastle.

With respect to the reversal of the prize cards in one class, perhaps Mr. Shorthose will state whether such reversal actually took place or not? If altered, it must have been by some one in authority, and it matters not by whom, the fact remains the same.

Your correspondent "J. I. D." by jumping at conclusions, for reasons apparent enough, makes the discovery from the Darlington catalogue that two Judges officiated in the Pigeon department, and although knowing "nothing whatever about Mr. Botcherby's capabilities," taking the presence of the second Judge into consideration, he "cannot think the awards were so outrageously bad."

It seems almost ungracious to dispel this illusion, but the simple fact is, the other Judge merely exists in the imagination of "J. I. D." for Mr. Botcherby officiated, as at Newcastle, *alone*; consequently, "J. I. D.'s" estimate of the decisions scarcely bears the significance he would make himself and others believe.

Then, relative to the other point—namely, "The silver cup for the best pen in the Show being awarded to an old Dun cock, a draft from the loft of one of our well-known exhibitors," "J. I. D." states he is prepared to prove that the bird was "under three years old," "and one of the best Carriers in the kingdom."

"J. I. D." has a task before him which is more likely to prove a fiction than the statements he impugns; and until such proof be forthcoming, your readers may infer that he is labouring under an hallucination, similar to that relative to his other Judge; and as his success has evidently been anything but "sour grapes" to himself, he will do well to rest on his laurels.—A FANCIER.

FOOD FOR CUCKOOS.

A CORRESPONDENT at page 142 wishes to know what description of food is best adapted for the cuckoo; and I think it may interest him to know that a friend of mine reared a young cuckoo last year, and from June to December fed it on chopped meat only. During the month of December, in consequence of alterations being made in my friend's premises, he removed the bird into a cold kitchen, where it died; and he ascribes its death entirely to the change of temperature, as it was in excellent health when removed.—W. GRIFFITHS.

I KNEW a cuckoo that was kept in a turnpike house in Monmouthshire through the winter of 1862. It was fed upon worms, bread-crumbs, and raw meat cut in small pieces. The bird was kept in a wicker basket cage. It was fond of bathing in a saucer, and when spring came was allowed to stay in the bath too long and died.—F. T. P.

WASPS VERSUS BEES—BARLEY SUGAR.

WHAT is the best plan of keeping wasps from consuming the produce of the bees? My bees are greatly teased with them this season. Although we have destroyed 160 wasps' nests within a radius of a mile, they seem now to be more plentiful than ever. How far do they travel? I have had one hive of bees entirely destroyed by them. A week since I went to look at my bees, as is my custom once or twice a-day, and I noticed that in one hive the wasps were going in and out with the bees. They seemed quite in harmony with each other. Not so the other hives, for if a wasp did present himself there was a battle, the bees generally proving victorious. I narrowed the entrances in all the hives, but it made not the least difference in the one alluded to, the wasps passed in and out just as fast as the bees. I watched them for some time, killing all the wasps I was nimble enough to get hold of, letting the bees pass unmolested by me, but it did not seem to make the least difference, for the more I killed, the more numerous they seemed to be, so I gave up the warfare.

I went again the next day, and behold there was nothing but wasps going in and out of that hive. I stayed some time

killing all I could get hold of as they were passing in and out, and at last I turned it up, and there was not a bee in it, nor any honey, and I believe the wasps were eating the comb. What had become of the bees, had the wasps killed and eaten them?

I see now that the wasps are visiting the other hives. One presents himself on the alighting-board of the hive, a bee attacks him, there is a battle, or more properly speaking a wrestle, the wasp generally is the victor, throws his antagonist off the alighting-board, and bolts into the hive. Should he meet with another bee, which is generally the case, he knocks that over, or to one side, and seems determined to go in; so I am in great fear I shall lose the whole of my apiary, unless I can stop the wasps in some way or other.

P.S.—What is barleysugar, and how is it made? I have seen it recommended for feeding bees, and I am sure I must feed mine, if the wasps let any of them live. I should have said that the most of my hives are the common straw ones.

—J. BURT, *Stapleton Gardens, Dorset.*

[We believe the defunct hive had lost its queen, and therefore, fell an easy prey to its enemies, whether wasps or robber bees, probably both. You seem to have rendered your bees almost all the aid possible by contracting their entrances, and destroying wasps' nests. We know not how far these pests may fly, but should fancy at least two miles. Try Mr. Taylor's plan of laying a piece of barleysugar across or just within the entrance of the hive, so as greatly to narrow it. "This," Mr. Taylor says, "is so attractive to the bees, that they muster at the door in greater force than the wasps durst venture to assail. As fast as the fortification is devoured it ought to be renewed, and the out-generalled enemy will retire from a hopeless contest." We shall be glad to hear if this mode of defence turns out successful. Strong stocks with narrowed entrances will probably hold their own until October, when the frosts of autumn may be expected to interpose decisively in their favour.

Give any little boy a penny in the neighbourhood of a confectioner's shop, and he will most readily show you not only what barleysugar is, but how speedily he can cause it to disappear. Instructions for making it are given in page 25, of the last edition of "Bee-Keeping for the Many."]

SELECTION OF QUEENS.

A SWARM came off from a frame-hive on the 16th of this month. Thinking that the old queen would be safer to keep than the young one so late in the season, I secured her in a tumbler whilst I removed the frames to search for the young queen. Not being able to find her, I swept all the bees off the combs, and returned the frames to the hive in which I set the old queen at liberty. The following day I found the young queen with a few hundred bees on a tree, secured her, gave the bees some honey, and they have all returned to the hive. I send you the queen, and will you tell me if I did right, and whether I gave myself unnecessary trouble in changing the queens?—A NOVICE.

[You certainly did quite right in endeavouring to preserve the old queen, which was a very fine one, and in the prime of life; but, unfortunately, your well-meant efforts have entirely failed. A post-mortem examination of the queen enclosed in your letter proves her to have been the original matron of the hive, whose untimely demise is much to be regretted.]

SMALL SWARMS FORMING GOOD STOCKS.

I READ with interest in the *Times* "A DEVONSHIRE BEE-KEEPER'S" reply to "A BEE-MASTER'S" letter which appeared in that journal. I noticed, and noted to a friend of mine, the numerous inaccuracies contained in "A BEE-MASTER'S" letter, but did not think them worth a reply or correction. Had not "A DEVONSHIRE BEE-KEEPER'S" letters appeared in your columns, I should have remained silent; but one paragraph of his letter warrants my troubling you with this communication. He says, "If any one has a swarm [of bees] consisting only of 5000 or 6000 let him not take the trouble of hiving it." And again: "A swarm consisting only of 5000 bees has, it is said, been kept through the winter

by feeding, and has done well in a magnificent honey season." He appears to doubt the truth of this statement, for he asks, "May we venture to ask for particulars?" Now, I do not question the fact in the least, for I have achieved a similar result with a third swarm, which I obtained near the end of July, 1863. I do not think there would be more than, if as many as, 4000 bees in the swarm; for when in a cluster they appeared to be of about the bulk of a three-gill jug. Soon after I obtained them the weather broke; and, doubtless you will remember that the "back end" of last year continued very wet. A friend of mine, also an old bee-keeper, told me that they were worthless. However, I was not content to lose them if they could be kept, so I began to feed them with sugar and water. The result is that this year, within twelve months after they were swarmed, I have taken 25 lbs. of honey from them, and yet have left them far more than will be sufficient to keep them through the coming winter. They are now fast filling a large bell-glass, and of this I intend to deprive them shortly. They were hived in an empty hive. They cost me 5s. for sugar. They were hived in an ordinary straw hive, but I have since driven them into a wooden hive. Now, had "A DEVONSHIRE BEE-KEEPER" given me his advice, and had I acted upon it, I should not now have had 25 lbs. of honey, 1 lb. of wax, and a splendid swarm of bees; for his advice would have been, "Do not take the trouble of hiving them."

Before I close, permit me to add that I find the best remedy for a bee-sting is to puncture the place stung till it bleeds; very little of the pain or swelling will be experienced after the part has bled a little.—A LANCASHIRE BEE-KEEPER.

[Few persons have any idea how many bees may be comprised in an apparently small cluster. Although, therefore, "A LANCASHIRE BEE-KEEPER" thinks there were not more than 4000 bees in his swarm, I hope, in the absence of more precise evidence, he will excuse my thinking that there might have been nearly double that number. It should be remembered, also, that I was combating Dr. Cumming's absurd estimate of 5000 or 6000 bees being the number of an ordinary swarm, when I pointed out by way of antithesis that so far from this statement being correct, such a swarm would scarcely be worth hiving. I am well aware that a comparatively small swarm of bees may sometimes form a good stock if liberally supplied with food; but the smallest I ever knew succeed in this way weighed 1½ lb. Casts of less weight are, of course, well worth hiving, with a view of uniting them to others; but as the attempt to form them singly into good stocks must certainly fail in the great majority of cases, a few isolated instances of success, even if proved beyond a doubt, which I do not consider has yet been done, would not invalidate the statement that in the long run such liliputian swarms are not worth hiving for this purpose.—A DEVONSHIRE BEE-KEEPER.]

OUR LETTER BOX.

PREVENTING WILD DUCKS FLYING (Château Vallon).—The only effectual way of pinioning wild fowl is to cut off the wing just above the spur. It is not a painful operation, and if the birds after the operation are turned into the water the bleeding stops, and there is no trace of the operation the next day. If you object to this, and wish only to cut feathers, cut down close to the quill as far as the first principal joint.

TURKEYS WITH SWOLLEN HEADS (M. H.).—Wash the head and face with cold water and vinegar. Feed on bread soaked in strong ale, and put camphor in the water they drink.

WHITE ELEVATIONS ON EGGS (M. C.).—The white spots on eggs are common occurrences, but are only noticed when on dark shells. It is no sign of disease. It is contrary to nature for your hens to be so broody, but as cooping for a few days usually cures them of it, we recommend you to use that remedy.

CHICKENS GASPING (J. M. A.).—From your description the gasping is incipient gapes. The only certain cure we know for it is camphor given internally in pills the size of a pea, and put in their water. Give them bread steeped in ale twice per day for three or four days.

DEATHS AMONG FOWLS (J. M. L.).—The Cochin-China hen died from the effect of the ulcerated leg, which wasted her to death; and it is probable the Polish died from fat, which very likely caused her to be egg-bound, and induced internal fever, which made her drink to excess.

CROOKS'S IMPROVED INCUBATORS.—Have any of your readers tried the above? If so, will they please report in your Journal what success they have had with them, and explain the method they adopted in using them, and how they reared the chickens hatched?—J. R. J.

MARRIOTT'S HIVES (W. G., Longton).—Marriott was a maker of bee-hives of all kinds. Those used by Mr. Piddington have Marriott's brass trade-plate upon them, and are the circular, straw, flat, wooden-topped hives with three bell-glasses and straw cap to cover them.

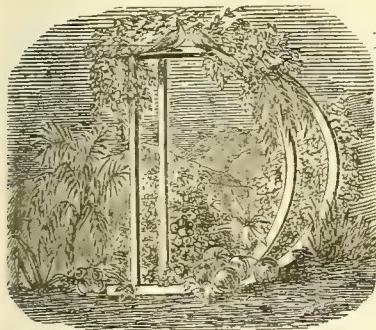

TAKING HONEY (M. C.).—We must first know what kind of hives you use before we can advise you.

WEEKLY CALENDAR.

Day of M ^{nth}	Day of Week.	SEPTEMBER 6—12, 1864.	Average Temperature near London.	Rain in last 37 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 69.1°, and its night temperature 46.5°. The greatest heat was 86° on the 12th, 1858; and the lowest cold, 30°, on the 6th, 1850. The greatest fall of rain was 1.27 inch.

CRYSTAL PALACE GARDENS, 1864.

ID you ever see a wedding without a bridegroom? Did you ever see a lady without a crinoline? Did you ever see a garden without grass? The first is a subject of natural history which we will leave the Registrar-General to answer; the second is a

phenomenon only now to be found at Vienna; but the last you may see any day at the Crystal Palace, and probably in front of your own window. Poor Mr. Gordon! Patience will do her perfect work with him this year—from the day of planting-out to this, except for a day or two, not a drop of rain, either early or late. Cold nights and hot sun and thousands of feet have done their work, and if any one has a common of good turf handy, doubtless the Directors will buy it at so much a foot to returf their lawns. Good grass seed will also be at a premium. Messrs. Greens' mowing machines have been laid up, and, well as they do their work, what is the use of them when there is no work to do? And where shall we get cuttings from for next year? There is Mr. Fish, too, patient man! I went to see Putteridge gardens four weeks ago, and glorious they looked; but Mr. Fish exclaimed directly he saw me, "I am glad you are come this week, for next week I shall not have a Calceolaria left, and I have only 6 inches of water in the tank, and not a drop will they let me have from anywhere else; for cattle must have drink, though flowers perish."

The gardens at the Crystal Palace, had the season been decent, would this year have been glorious. There are some beds, also, which, notwithstanding the dryness, are very good: we shall come to them as we walk about. Next year, they tell me, there will be a station under the Palace, and you may be hoisted up into the building like a bale of goods, and stand at once, without fatigue, with the ices and other good things on one side and the gardens on the other; but this year I must request you to enter the gardens from the old station (a very dirty station it is, by-the-by), and you have the Rose Mount before you. A walk leading up the Mount, with four round beds on the left, a heart-shaped and two round on the right, directly faces you. The heart-shaped bed on your right has for centre Cottage Maid Geranium, then two rows of Crystal Palace, edged with Flower of the Day. Of the two round beds above, the first has for centre, Pelargonium Floribunda, a good white, edged with Golden Ivy-leaf Geranium; the second, for centre, Baron Ricasoli, one of the best of poor Mr. Beaton's last productions, edged with Crimson Minimum, a great

favourite of mine, so dwarf and compact, and, like a true Nosegay, an abundant bloomer. On the opposite side of the walk, supposing you are returning downwards, is a splendid bed of Geranium Brilliant, edged with Baron Hugel; next, Mrs. Whitty, edged with Golden Chain; then a bed of Trentham Rose Geranium, edged with Purple King Verbena; and at the corner facing the heart is a bed of a seedling Tropaeolum, edged with Mangold's Variegated Geranium. Tropaeolums are not suited for dry seasons; red spider attacks the leaves, and grow they cannot.

There are six walks leading up to the Mount with beds on each side. From two to four beds occupy the spaces between the walks. Supposing you are now on the great walk encircling the base of the Mount and going towards the Palace, you have the Mount on your right. Two beds occur here between the first and second walk. The first is a full moon of bright pink. Its centre is the loveliest of all pink Geraniums—Sidonia, with two edgings; the inner of Countess of Devon, a pretty little half-bred between the Fancy Pelargonium and the sweet-scented Hybrid Perpetual section; the outer edging is Lobelia speciosa. The next bed is filled almost to overflowing with Lord Palmerston Geranium, leaving just room for an edging of Cloth of Gold. It is a pity that the whole Mount is not surrounded with beds equally attractive with these two last; but they fail in half their effect for want of the green setting of live grass.

A heart-shaped bed at the corner of the next walk has Christine for centre, two rows of Flower of the Day all round, and an edging of a seedling Lobelia of Mr. Gordon's, something like Paxtoniana, named Delicata. To this walk there are given only four beds; of the two on the right-hand side, the first is Calceolaria Prince of Orange, edged with Lady Plymouth Geranium; the second is Alma mixed with Lobelia speciosa, a salad bed. Of the two on the left-hand side of the walk, the first is Beaton's immortal Geranium Stella, edged with Geranium Pretty Polly; the second is dark Calceolaria, seedlings of Mr. Gordon's, edged with Lady Plymouth. Between this and the next walk there is one round and two heart-shaped beds; the first, the round one, is planted in alternate circles with Blackheath Beauty Geranium, Golden Chain, and Lobelia speciosa; the heart bed, where a walk branches off to the Palace, is Crystal Palace Scarlet Geranium, edged with Gnaphalium lanatum; and the other heart-shaped bed at the corner of the next walk up the Mount, where there are two Elm trees with seats underneath, has for centre Geranium Cottage Maid, two rows of Gaines' Yellow Calceolaria, edged with two rows of Christine Geranium, with a fringe of a new Lobelia. At this walk, besides the heart-shaped bed at the corner, there are two on the right hand going up, and four on the left. The two on the right hand are, first, Cloth of Gold Geranium, mixed with Lobelia Delicata (in some lights a very effective bed); second, Tropaeolum, edged with Cerastium tomentosum.

Returning down the walk, on your right you have, first, a seedling Tropaeolum, edged with Cerastium Bie-

bersteinii; second, Geranium Cloth of Gold, mixed with a seedling Lobelia of a true blue colour, but weakly in habit, raised by Mr. Gordon, called Blue King; the third bed is a dark Calceolaria, edged with a dwarf Fuchsia; the fourth has been altered from its first pattern, which did not answer, to a mixture of Geraniums for the centre, edged with variegated Coronilla. Between the walk just described and the next are three round beds and a heart-shaped one. The first is Lobelia Blue King, mixed with a Verbena which will not grow; the second, Lobelia Gordoniana, edged with Geranium Flower of the Day; the third has for centre Geranium Emily, edged with Floribunda Geranium, and a curious little Geranium which I believe goes by the name of Black Prince; not, however, to be confounded with the Hybrid Perpetual of that name. The heart at the corner has Purple Nosegay for centre, two rows of Crystal Palace Scarlet all round, and is edged with Purple King Verbena. To this walk there are two round beds on your right going up, and four on your left. The first has Geranium Comte de Morny for centre, edged with Cloth of Gold; the second, a mixture of Lilac Ivy-leaf and Verbena Melindres, edged with Golden Ivy-leaf.

Returning down this walk you have on your right four round beds; the first, another mixture to correspond with the bed opposite, of Crimson Ivy-leaf and Verbena Empress Eugénie, edged likewise with Golden Ivy-leaf; the second contains a new Geranium, a seedling of poor Beaton's, which he himself thought and wrote highly of, but which rather disappointed me—viz., Cybister, edged with Cloth of Gold; the third is Gazania splendens, edged with Alyssum; and the fourth is a bed of Heliotrope. Between this last and the next heart-shaped bed are four round beds; the first is Cerise Unique Geranium, edged with a white Verbena; the second, Verbenas, centre Great Eastern, edged with a darker kind (I dislike Verbenas put next each other); the third, Tropaeolum Triomphe de Hyères, edged with a darker Tropaeolum; and the fourth Golden Chain and Beauty of Blackheath Geraniums in alternate circles. The heart-shaped bed has Perilla for centre, two rows of Gaines's Yellow Calceolaria round it, then two rows of Crystal Palace Scarlet Geranium, two rows of Prince of Orange Calceolaria, and an edging of Tropaeolum elegans. A remarkable bed, and on the whole very telling.

We are now at the fourth walk up the Mount, on the right of which are two round beds and three on the opposite side. The first on your right going up is Cerastium tomentosum, mixed with Lobelia speciosa; the second is Geranium Lord Palmerston, edged with Baron Hugel. Returning downwards, on your right is a bed of the Hybrid Perpetual Geranium King Rufus, edged with Geranium Crimson Minimum; next stands a bed of Blue King Lobelia and Variegated Alyssum mixed; while the third, at the corner, has for centre Crimson Minimum Geranium, edged with Floribunda.

There are four beds between this and the next wall; the first is planted with dark Calceolaria, edged with Geranium Golden Chain; the second has for centre Nierembergia gracilis, edged with Nemophila prostrata; the third, Tropaeolum, edged with Variegated Alyssum; and the fourth, Prince of Orange Calceolaria, edged with Heliotrope Miss Nightingale. The heart-shaped bed at the corner is nothing particular, but going up this, the sixth walk on your right, are two round beds, the first containing a scarlet Verbena, edged with a white one; the second, a fancy mixture of variegated Geranium Prince of Orange, and a dark Verbena, edged with Golden Chain Geranium.

Turning down again you have on your right four round beds; the first is Verbena Melindres, mixed with Geranium Lady Plymouth, edged with Geranium Golden Chain; the second, Purple King Verbena, edged with a white one; the third bed is Fuchsia fulgens, edged with a white one; the fourth, Gazania splendens, edged with Arctotis reptans. We have now only three more beds, and we come to our starting-point. The first at the corner is a mixture of Geranium Dandy and Lobelia speciosa; the second is planted with one of the Hybrid Perpetual Geraniums, edged with Cineraria maritima; and the third and last with Gaines's Yellow Calceolaria, but the edging I do not remember.

At the upper part of the Rose Mount is a bed going all round outside the arches, forming a sort of collar to them. It is planted this year with a zigzag pattern of Geranium Christine, Purple King Verbena, Geranium Flower

of the Day, Calceolaria Aurea floribunda, and Lobelia Paxtoniana. It would have been very effective. As it is, except on the east side, owing to the want of rain, the plants have grown smaller and smaller every day.

The beds I now propose you to look at are those on each side of the grand central walk leading from the central basins to the upper terrace. They consist of round and long beds; the round are planted with Perilla for centre, a circle of white Pyrethrum, and then a circle of Crystal Palace Scarlet Geranium, edged with Mangles' Variegated Geranium. The long beds have a stripe of Geranium Trentham Rose down the centre, a stripe of Aurea floribunda Calceolaria on each side, then two rows of Christine Geranium, and an edging of Purple King.

The upper terrace is very gay, though not up to its usual mark. Let us begin at the west end, and we have five round beds separated by beds of evergreens. The first round bed at the west-end of the terrace has for centre Geranium St. Clair, a circle of Beaton's Nosegay Black Dwarf, a circle of Cloth of Gold Geranium, edged with Blue King Lobelia. The second bed has for centre Beaton's Nosegay Geranium Baron Ricasoli, a circle of Geranium Golden Chain, a second circle of Geranium Beauty of Blackheath, a third circle of Geranium Silver Queen, edged with Lobelia speciosa. The third bed has for centre Perilla, a circle of Centaurea candidissima, a circle of Geranium Golden Chain, edged with Lobelia speciosa. The fourth bed has for centre Centaurea candidissima, a circle of two rows of Amaranthus melancholicus ruber, another circle of Geranium Cloth of Gold, edged with a little pink-flowered Mesembryanthemum or Sedum. The fifth bed has for centre Peirilla, a circle of Centaurea gymnocarpa, a circle of Geranium Golden Chain, the whole edged with Blue Lobelia.

These five beds, as well as the five corresponding to them at the east end of the terrace, which are planted bed for bed exactly alike, are trial beds, in which new Geraniums or bedding-plants are tested, and new combinations proved. Geranium Black Dwarf is comparatively a new one, and a great beauty; very dwarf, large full trusses, and rich healthy foliage. The variegated Geranium Silver Queen was brought out by Messrs. Henderson some years ago. There are now several improvements on it, Oriana Improved being the most recent. Geranium Blackheath Beauty might be greatly improved; it is not satisfactory, though the best of the salmon colour. It is used very effectively in a bed on the Rose Mount in alternate circles with Golden Chain Geranium.

We are now at the west end of the semicircular walk which bisects the great terrace. On our right are a series of circles surrounding vases and statues: these are planted chiefly with Geraniums Trentham Rose, Crystal Palace Scarlet, and Christine, edged with Flower of the Day. You will have no difficulty in making out such well-known favourites.

On our left, however, are some novelties. Observe, there is an outer edging of Lobelia to each bed, while a string course, marked by using variegated Geranium Flower of the Day, divides each bed into three parts, and four little angles are formed by the intersection of the string course. Well, in the first bed at the corner on your left, Lobelia Paxtoniana goes all round; the two end divisions are Geranium Lucien Tisserand, the centre Hybrid Perpetual Geranium Diadematum erubescens, while the little angles are filled with Harkaway Geranium. The second bed at the two ends has Geranium Sidonia, central division a dark Calceolaria, name unknown, while the angles are Geranium Harry Hieover. These two liliput Geraniums, Harkaway and Harry Hieover, are used alternately in the angles of each bed; I shall not, therefore, repeat them in each case, but only give the two ends and centre. The third bed has at each end Tropaeolum elegans, Helen Lindsay in the centre. The fourth has Geranium Madame Vaucher at the ends, Nosegay Geranium Black Dwarf in the centre. The fifth has Prince of Orange Calceolaria at the ends, Geranium Fatinitza in the centre; and the sixth bed has for ends Shrubland Rose Petunia with a centre of Nosegay Geranium Stella. These six beds are repeated bed for bed on the opposite side of the half circle, except the one at the corner next to the grand terrace walk, which for ends has Blush Minimum Geranium, with G. Diadematum erubescens for the centre.

The chain pattern in the sunk panels is remarkable chiefly for the number of yards of Variegated Alyssum. They

looked very well from the balcony of the Palace, though perhaps by the time this appears the Calceolarias are out of bloom.

The grand terrace is gay as usual. The beds here at all events have not done badly. Mr. Vyse has plenty of water close at hand. The long beds have for centre Geranium Cottage Maid, a stripe on each side of Geranium Flower of the Day, edged with Verbena Purple King. The round beds have Geranium Christine for their centre; then a circle of Aurea floribunda Calceolaria, edged with Lobelia Paxtoniana.

On the whole, though Mr. Gordon has displayed his usual talent, and invented many new combinations of colours, the Crystal Palace Gardens this season cannot give the usual satisfaction. The want of grass, and even the dustiness of the shrubs, leaves nothing for the eye to rest upon; and though the papers speak of heavy rain on the Foresters' fête day, it came too late to do any good. To Mr. Gordon we have been indebted in former years for many bold but beautiful combinations of colour; as, for instance in 1860, when the grand terrace long beds were planted with Crystal Palace Scarlet Geranium for centre, Verbena Purple King on each side, edged with *Tropaeolum elegans*—nothing could exceed the beauty of those beds that year. Then, I think, the next season the same beds started more criticism than was pleasant at the time. What! scarlet and pink next each other! and yet those beds have been imitated by almost every lady who plants her own garden. The fact is, the effect of colour produced by flowers with the various accessories of foliage, and light and shade between the leaves, can never be judged of by the same rule as you would decorate a room or design a ribbon; and this Mr. Gordon found out, and he has gained a celebrity for good judgment and taste second to none.—F. W. ADEY.

HOUSE FOR VINES, PEACHES, AND GREENHOUSE PLANTS.

THE following is in answer to "N." and other inquirers on the same subject.

The house which you have moved from one place to another is 56 feet long, 17 feet wide, and 13 feet to the apex, there being a short hip behind of slate; the sloping roof is of fixed sashes; ventilation by boards in the back wall below the slating, and by sliding 3½-feet sashes in front. 23 Feet is to be appropriated to Peaches, and separated by a glass partition from 33 feet for Vines. It is intended to have a stage against the back wall for plants, and a raised bed inside in front, separated from the part behind by a wall 2½ feet in height, and connected with an outside border by means of arches and brickwork beneath the sill-plate on which the upright moveable sashes are placed. Heating is proposed to be effected by a tile flue along the back wall, and a four-inch pipe on a raised brick curb a couple of feet or so above the flue, returning in a chamber beneath the pathway, with a grating over it. Counsel is asked as to external, and more especially as to internal, arrangements; and if we do not follow exactly the line of your separate questions, it is that "C.," "A LOVER OF PLANTS," and "AN ADMIREER OF THE VINE," may be answered also at the same time, as they with you desire no more heat than will just keep plants safe and mature the fruit without forcing.

First, then, as respects the roof, which is in front of three divisions of sashes, there is no objection whatever to its being fixed; but as, independently of the shade of the rafters, the sash-bars are not more than 5 inches apart, and the glass in very small squares, we certainly should not have contributed to the shade in dull weather by having a short hipped roof at the back formed of slate. In a very cold exposed place such a roof on the north side might be justifiable on the score of protection, but on no other consideration, as to make that slate roof secure would, we think, cost rather more than a fixed roof of wood and glass. For such a roof, and glass 5 inches across, from 2 to 2½-inch sash-bars would be sufficient, and without any rafters, so as to harmonise with the glass in front; and we think that, independently of the appearance and the additional light thus given to fruit and pot plants, the expense would be less than the secure slated roof.

Secondly. The proposed ventilation will be ample without having any of the roof-sashes to move; and this of itself is a great matter of economy in labour and expense, as sliding sashes on the roof are always attended with liability to smashes and crashes.

Thirdly. You propose the inside border to be 7½ feet wide and the outside much the same; and for a house 17 feet in width we do not think that is too much. But as you evidently wish to limit the width of these borders you may with propriety make them 12 or 18 inches narrower both inside and outside if it serves any peculiar purpose, such as having more room for a stage behind, as both Vines and Peaches will thrive in narrow spaces if they are well fed from the surface. We would not, therefore, altogether object to a border of 10 feet; but if there was no objection to doing so, if we curtailed the inside to 4 or 5 feet instead of 7½ feet, we would widen the outside proportionally, so as to make it some 14 or 15 feet altogether. Ten feet altogether, or even less, would do if there were any particular object to serve and rich top-dressings were given; if not, it would be well to have from 14 to 15 feet in width altogether.

Fourthly. It would not be wise to make up a deficiency in narrowness by depth. If at all in a damp neighbourhood it would be well not to sink the border much below the ground level. We presume from your drawing that outside and inside you propose your border altogether to be 5 feet in depth, something like half being above the ground level and half below it. We would advise making it little more than 3½ feet; and of that, besides the drain, taking 15 inches for open rubble at the bottom and 27 inches for soil. This would secure the soil for the roots being entirely or nearly so above the ground level. The inside border should not slope from front to back, but if not level should slope from back to front, and, instead of being lower, should be an inch or two higher than the outside border. No greater error can be perpetrated than planting trees in a low border inside, and expecting the roots to find their way through arches into a border a foot or 18 inches higher outside.

Fifthly. No better plan for security can be found than building the front wall on arches. In many cases the top of the arch is made too low to be fully serviceable. In your case the inside and outside soil seems to rise some 15 or 18 inches above the top of the arch, and roots must descend that depth before they can get out. We would like the crown of the arch to be within a few inches of the surface—in fact, for combining economy and suitability, we would have no arches at all, as you show no brickwork outside the house; but we would have piers of the necessary height, 4 feet apart, as you have them, and on these piers we would place a sill of iron, or of stout wood lined with galvanised plate iron or lead beneath, and pack the soil, inside and outside, up to it. When the soil sunk a little there, we would just add a little more, to prevent any air entering there. This would suit the roots of Vines and Peaches much better than having the crowns of arches sunk much beneath the surface-level. The only objections are the necessity for protecting once or twice a-year, and the greater facility given for the entrance of vermin, as rats and mice; but even the arches will not prevent that if the vermin are not looked after. We caught a mole the other day in the viney, where he was burrowing famously, but we can hardly conceive how he could have got in, except by burrowing beneath the foundations. Like thieves, vermin are not easily kept out when they are resolved to go in.

Sixthly. As to heating, the furnace and boiler are well placed, provided you need them both, as the top of the boiler will be lower than the level of the floor. We cannot say, however, that we approve of your mode of heating, as, in a house 17 feet wide, the heating power will be against the back wall of the house, the return single four-inch hot-water pipe only being placed in the middle of the house, and that sunk underneath a grating. There seems to be no necessity for sinking such a pipe at all. The heating would be far more effective if you took the flow and return across one end, and placed them side by side, some 30 inches from the upright front sashes, and 2 or 3 inches above the level of the inside border. Small piers there, every 9 feet or so, according to the length of the pipes, would cost no more than the wall on which the pipe rests close to the back wall, and you would escape all sinking of the pipes along the

floor, and the attendant grating. We would leave the flue as you propose, close to the back wall; and when you put on a fire it will enable you to give air by the wooden ventilators on the north side more freely. You speak of a twelve-inch tile flue. Is it to be covered by tiles of that width, or is it to be made of earthenware pipes some 12 inches in diameter? If the latter, the first 6 feet of the flue from the furnace should be built of bricks in the usual way, and at the end of that, and the other end of the house, there should be square places of a foot left, so that the flue could be cleaned without moving the round pipes. Portland cement is the best material for fixing such pipes, so as to keep them smoke-tight. The next best is fine lime, putty, and sharp sand.

Seventhly. If these two divisions were to be heated separately, it would be best to place the boiler between them, and take the pipes right and left, to be worked together or independently of each other. If the same flue and pipes are to heat both divisions, without any valve or other stoppage—that is, when you heat one house you must also heat the other—then it will be best to have the stokehole, flue, and boiler placed at the extreme end of the vinery. The flue and the flow-pipe there will always be warmer than at the other end; and Vines, when in a state of rest, will bear more heat than Peaches will do in a similar condition. You may safely keep a temperature of from 40° to 45° from fire heat in your vinery all the winter without prematurely exciting your Vines. You could hardly do the same thing long in a Peach-house, if the temperature from fire heat went much above from 37° to 43° by fire heat. In the vinery, therefore, you could keep in winter plants needing the most heat; and the temperature in the Peach-house you could keep lower by giving more air, and use it for hardier plants. For instance: you could keep Camellias, Geraniums, &c., in the vinery; Verbenas, Calceolarias, &c., in the Peach-house, and yet bring forward the buds in neither house much before their usual time.

Lastly. If the Vines are thus allowed to break naturally, most greenhouse and bedding plants may be kept in it from the time the Vines are pruned until the fresh leaves begin to impart too much shade, when a few things that delight in shade—as Ferns and Begonias, might be grown on the stage in summer, and tender annuals if the stems of the Vines are 3 to 4 feet apart. Similar treatment, except a lower temperature, may be adopted in the Peach-house until the bloom is set, and before the foliage is much expanded. If the trellis for the Peach trees extends all over the roof, up to the top of the back wall, then you will grow nothing well on your stage in summer except what loves the shade; but as soon as the leaves are off the trees in the autumn, you may fill your house with plants until the fresh leaves of the following year make it too shady. One of the best modes for combining the useful and the ornamental in a Peach-house, with the roof covered by the trees, that we have met with, was not having any stage, but covering the back wall with Camellias, and setting plants on boards on the floor in the winter. From November to April the wall was a beautiful sight. The shade in summer just suited the Camellias, and the leaves of the Peaches were gradually thinned in the end of summer to secure the ripening of the buds. It would be a bad policy to have many plants in either division when the fruit was ripening.

The stage may come far enough forward to secure from 30 to 36 inches for a pathway between it and the raised bed in front, and a moveable trellis might also be laid across that bed, so that every part of the interior could be a greenhouse in winter. This, with a little care, need interfere nothing with the health or the fertility of the fruit trees.—R. F.

THE MUSCAT GRAPES.

THE question of the difference between the several varieties of Muscat Grapes has at length been settled by the Fruit Committee of the Royal Horticultural Society on Tuesday last. For many years there has been a great diversity of opinion among Grape-growers as to the characters of the various forms of the Muscat of Alexandria; and by way of ascertaining and determining wherein these differences lay, the Fruit Committee obtained from the most authentic sources the following varieties, which were all

planted in the same house, set apart exclusively for that purpose:—Muscat of Alexandria, Muscat Escholata, Barnes' Muscat, Tottenham Park Muscat, Denbies Muscat, Charlesworth Tokay, Tynningham Muscat, Passe Muscat, Bowood Muscat, and Canon Hall Muscat. The last has always been allowed to be distinct from the others, and is at once known by its very large and almost round or roundish oval berries. After having grown these varieties under the same conditions in a Muscat viney, and fruited them for two years past, the Committee after very careful comparison came to the conclusion that Muscat of Alexandria, Muscat Escholata, Barnes' Muscat, Tottenham Park Muscat, Denbies Muscat, and Charlesworth Tokay, are all the same variety under these different names; and that Bowood Muscat, Tynningham Muscat, and Passe Muscat, differ from the others in being much better setters, but that these three bear a close resemblance to each other. Thus this vexed question of so long standing is settled in a way and through a process that can leave no farther doubt on the subject.

MY ORCHARD-HOUSE—No. 8.

AFTER a two-months drought this island was suddenly visited by a violent storm of wind from the north-east, accompanied by heavy rain, on Monday the 22nd ult. Many visitors, during this the season, had occasion to remember this date, as special excursion trips had been organised by sea and by land. About three hundred (among whom was this Journal's correspondent), had started early on board a small steamer for Serk, eight miles distant. The morning was overcast, and rain clouds were massing themselves gradually in the eastern sky, but no one anticipated the storm of wind and rain which obliged us, together with another strong party of excursionists from Jersey, to seek shelter all over the island, and finally to re-embark, from an open beach, in crowded boats under a drenching sheet of rain. Huddled together on the open deck, unable to move hand or foot, the violent lurchings of the steamer (whose only safety lay in its splendid pilotage), produced a succession of ludicrous episodes, such as are only to be met with in "pleasure trips." Many of the female excursionists had already been laid prostrate on the beach after the journey out, and on their return their sufferings were great indeed. I do not think we were sufficiently thankful, at that dismal period, for the heavy rain, under which the very waves appeared to smoke. The island pastures, however, burnt to a pale yellow, seemed to rejoice under the welcome downpour, which was truly valuable after so long a drought; and our tanks became completely filled during the night. I do not remember this as having ever occurred in one night before.

The violent gale increased during the night, and the next morning the ground was strewed with leaves, and, alas! many a fine Pear and Apple. At such times one is apt to reflect on what is really the best form for a standard fruit tree to assume. That form which best obviates the risk of the boughs clashing together, is not always the one most favourable to admit the sun's rays equally over the tree. In these stormy isles we are not agreed on this point. Some are strenuous advocates of the pyramidal form both for Pears and Apples, and it certainly seems the best calculated to prevent the lateral branches from rubbing together. Observe a bush tree trained in that beautiful shape "*en goblet*" in a gale of wind. See how the branches intermingle as they sway in the blast, rubbing away shoots and fruit; but what an admirable plan to admit light, warmth, and air to all parts alike! Supports, ties, wires, have all their objections.

In the orchard-house all was calm and fair on my return. The ventilators to windward had been closed, those to leeward were left open, and only a grateful feeling of shelter and pervading moisture met me after so much exposure. This was one of many moments when the protection afforded by glass structures to such valuable fruit as Peaches and Nectarines, then in the very height of their season, was fully demonstrated. Not only so, but it was inexpressibly delightful to find oneself thus able to pace along the planked path (a plan I strongly recommend to amateurs), heedless of the raging wind and cold rain outside of the house. All the beautiful fruit still hanging on the trees seemed to welcome their master back.

There is a point of view from which we should sometimes survey our orchard-houses. It is the shelter they give us, in addition to the fruit, which is so valuable. Avoiding as much as possible the midday sun, in the early morning and late evening, on a calm summer moonlight night, or on a wet and windy day in autumn—where is there a healthier or more agreeable lounge? New and rare fruits develop themselves under our eyes, we watch their various forms and different colours with always a new pleasure, and when at last we gather them, and sit in solemn judgment on their merits, there are few purer amusements in this world, and not many obtainable at so easy a rate. An amateur in ten years sees and knows actually more about the habits of these first-rate fruits than his ancestors did about ordinary specimens in a century. He has them all present, side by side, growing under precisely the same conditions, and so can readily compare them. The cultivation in pots enables him to multiply them, and to fruit them sooner.

The back wall of our house, 125 feet long, is planted with trees trained *en cordon*, an excellent plan, and which must eventually supersede large fan-trained trees under glass. These trees are planted at intervals of 3 feet, and trained as diagonal cordons at an angle of 45°. The shoots are pinched in much as those on the potted trees are—that is, closely spurred, and they produce well. But their best recommendation is that by this means the wall is clothed much sooner, the trees are kept more in hand, become sooner fruitful, and a greater variety of sorts is obtainable. We begin one end of our wall with an early July Peach, and end it with a November Peach. For about four months that wall absolutely shines with splendid Nectarines and Peaches of rare and delicate habit. For that period I am able daily to place a dish on the table such as few could match. Some fine new orchard-houses in both islands are organised on this system. In one, in particular, which is worked by the only gardener in Guernsey who knows anything about orchard-houses, in this, the first year of bearing, about 320 splendid fruit were grown. In Jersey a noble house now building, in the form of a T, which I have had the pleasure of organising, is also on this system, and I have no doubt will be equal to most good houses even in England.

The difficulty in every case has been to find gardeners willing and able to manage these new structures. When beautifully finished, and stocked with trees in a bearing state, incredible errors continually occur. This is the true cause of failure. From what I have seen I am ready to believe any amount of mistake; but the system itself is sound and practicable. No doubt we have much to learn still, but we shall learn it. One thing I myself have found out, which some years ago seemed out of the question, and that is, that orchard-houses must not be narrow. When trees become of a certain size they are difficult to manage. All previous arrangements are upset, and expensive changes occur. Therefore, let us build our houses of a good width at the first. The amount of fruit that is wasted from inability to gather it without knocking down the produce of surrounding trees is very great. To prune a few summer shoots costs at such times a dozen Peaches. As all that falls is valueless, even for home consumption, this evil requires a strong remedy. Again: narrow houses are subject to sudden draughts, which shake down many a fine fruit; these houses are also more liable to attacks of red spider. The trees which are in untidy corners are the first attacked; then if, as during the last month, tanks fail, and fierce gleams of sun fall on leaves near the glass, that which is at all attacked by the red spider is sure to dry up and wither. The tree has then to make new leaves, and cannot do much with these for next year's crop.

We have gradually left off syringing, as, without more care than can be expected of a servant, the force of the water loosens the fruit more or less. Watering at the roots is still of great value, though not so much so as during the time the fruit was swelling. Apricot trees after fruiting require far less water; indeed, their leaves never droop now. The second crop of Figs remains small, too small for success. Irregularity of watering is the cause, as "R. F." says, and he is always right.

The growth of our orchard-house trees has been chequered this year. The early shoots had a hard battle for life with successive attacks of green fly, and the later ones are ripe,

but feeble. August shoots are more vigorous, but no dependence can be placed on these for fruit even here. It is probable that these if left would carry us as far as the blossoming process, or even the stoning, but no further; so, if not of a fit colour, these are to be shortened-in in October. The long drought and heat, however, has been generally favourable to all fruit trees.—T. COLLINGS BRÉHAUT, Richmonde House, Guernsey.'

ORCHIDS AND GRAPES.

We some time ago, in speaking of Mr. Warner's cool Orchid-growing, remarked that this was conducted in an ordinary viney, under Vines which are trained up the rafters; and we remarked at the time that upon such a system not only could the Orchids be grown with perfect success, but an excellent crop of Grapes could be obtained, which would go far in reducing the expense of the fuel required to keep out the frost during winter.

As an evidence of the truth of this, we received from Mr. Warner the other day a bunch of Black Hamburg Grapes, which in size and colour was in fine condition. It was a fine tapering bunch, well shouldered, and weighing 1 lb. 5 ozs. The berries were large, the bunch having been judiciously thinned at the right time. The colour was quite black, and the flavour excellent. With such an example before us none need despair of growing Orchids and Grapes in the same house. In a note which accompanied it Mr. Warner says:—

"I send you a bunch of Grapes from one of the houses you saw when at Broomfield. Brazil Orchids, Guatemala Orchids, and Indian Orchids, such as *Dendrobium nobile*, have been grown and bloomed well in this house."

"You will know from the colour of the Grapes that abundance of air must have been given. The roots of the Vines are confined in a brick pit inside the house on a clay subsoil. If a good well-drained border could be given them the bunches and size of the berries would be much larger."

"WATER, WATER EVERYWHERE!"

WHAT a blessing to live in a well-watered country! Hertfordshire for the greater part is a county remarkable for its pretty undulations, the valleys teeming with springs and small perennial streams. The district to the east of Hertford to Sawbridgeworth, the extreme eastern point of the county which there joins Essex, is highly favoured by springs in the little valleys, often on the surface, and always at a small depth beneath it.

The years 1825, 6, and I think 7, as far as I recollect, approximated to this season and the last. Water became scarce, and I had a new well 8 feet in diameter dug in a sandpit. On reaching a depth of 24 feet a beautiful spring was found, which rapidly rose so as to stand 8 feet deep of water. It has continued to this day to furnish abundance, and has never failed, although from ten to fifteen thousand gallons of water have been pumped daily since the beginning of May, with a pump worked by a pony, into a large elevated tank which supplies several others at a lower elevation.

Last season I somehow instinctively anticipated a dry summer this year, and fearing that one well might fail—in fact, I was alarmed on thinking of the consequences of water failing—I selected a site at the foot of a hill some five or six hundred yards from the other well, and had another dug of the same diameter. On reaching the depth of 15 feet the water rushed up through the sand and stood 10 feet in depth. My original well has once or twice required one or two hours' rest in the middle of the day, but the water has soon flowed in rapidly, and now stands at 5 feet; in my new well it stands at 7 feet. They both seem inexhaustible. I have been tempted to write a few lines about the water from these wells because I observe Mr. Robson gives directions respecting the use of well water. Our water is full of carbonate of lime, so much so, that the stems of orchard-house trees syringed with it become at the end of the summer quite white. It is, therefore, what is called hard to a certain extent; still there must be some quality in it favourable to vegetation, for when exposed to the sun for thirty,

six hours, the second day a miniature forest of confervæ is seen springing from the bottom of the tank, looking so delicate and feathery that no fernery can equal it. The oddest thing about this well water is, that owing to the enormous quantity required hourly in hot weather, it is used without being exposed to the air, and yet it gives most extraordinary health and vigour to the many thousands of Vines and trees in pots it is given to. This is so against all rule that I am tempted to write it to show for the thousandth time, "There is no rule without an exception." I may add, that our surface springs in our little valleys are still running freely, making us truly grateful for "water, water everywhere!"—T. R.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 30TH.

FRUIT COMMITTEE.—A meeting of the Fruit Committee of the Royal Horticultural Society was held at Chiswick on Tuesday last, George F. Wilson, Esq., in the chair. The object of the meeting was to examine the collection of Muscat Grapes which has been planted in a house devoted exclusively to their cultivation. The result of the observations of the Committee will be found in another paragraph of our present Number. It is quite evident that there are but three distinct forms of white Muscats, the white Muscat of Alexandria, the Bowood, to which Tynningham and Passe Muscat are very similar, and the Canon Hall.

Mr. Veitch, of Chelsea, exhibited one very large and two smaller bunches of Muscat Champion, or as it was formerly called, Champion Hamburg Muscat, a name quite inapplicable, seeing it has no relation to the true Muscats, except that it has a Frontignan flavour. The name will, therefore, henceforth be Muscat Champion, from its being raised from Champion Hamburg crossed by Canon Hall Muscat. The berries were large and well grown, and the colour was better than when it had been shown on former occasions, but it was still deficient of the true black which it is, no doubt, capable of receiving when better cultivated. In regard to flavour it maintained the high opinion the Committee formerly expressed upon it.

In the house containing the collection of Muscats, there is a Vine of Trovèren Frontignan, producing fine bunches and large round berries, the flavour of which is very rich and vinous. The Committee recommended this variety as one of first-rate quality.

The Committee then proceeded to the examination of the collection of Plums grown on pyramid trees, and among those recommended as first-rate dessert sorts were Angelina Burdett, Belgian Purple, Reine Claude Violette, Jefferson, Prince Engelbert, and Denniston's Superb.

AN ORCHARD-HOUSE EXPERIENCE.

I HAVE for some time past wished to communicate to your readers my experiences of orchard-house culture. My not being a professional will be an objection in the eyes of some people, my being but an amateur will have weight with others. I am but a young hand at any kind of gardening. Until the summer before last I had never grown a Peach, and until 1860 I had not a foot of garden ground. I have had everything to learn, and when a man gets beyond fifty it is not always easy to acquire; at the same time I had no old theories or prejudices to get over.

Last March two years I bought four trees in pots, and the Peach tree produced me four handsome fruit. I was delighted, and having seen Mr. Rivers's book on orchard-houses, I determined to try my hand at that mode of culture. In the autumn of 1862 I went to Sawbridgeworth, and saw Mr. Rivers's houses and trees, and purchased some of the latter. Last summer (1863) I had some very fine fruit, and in the winter I built an orchard-house.

This spring my trees were very handsome while in bloom, and the fruit set on all kinds very freely. Peaches, Nectarines, and Apricots, of course, I had to thin out again and again. In June I showed six trees at the Isle of Wight Horticultural Society's Show at Ryde. They were much admired, being clean, and loaded with fruit. One of the

Peach trees, Padley's Early Purple, bore four dozen, and I was reminded by a friend who is clever in his profession, that the fruit would be small, that my trees were overstocked, &c. I thought so too, but replied we shall see. That tree ripened three and a half dozen of Peaches, which sold at 6s. per dozen, and the other half dozen were larger than my friend produced in his house.

The season has now passed. I have gathered sixty dozen of the several kinds of Peaches, Nectarines, and Apricots. All my trees are in pots. Every tree is clean, and the fruit-buds well developed. I have not a single bad tree, and more, I have not used smoke or sulphur during the whole summer. I commenced gathering in the middle of July. Peaches, home and foreign, are as plentiful as Apples just now; but the trade will give me 1s. 6d. per dozen more for mine than for the best out-door brought to them.

My trees are young, but they have ripened one dozen and a half each on an average, and all fine fruit, many weighing 7 and 8 ozs.

At the Isle of Wight Horticultural Society's Show, held on the 17th ult., I exhibited twelve Peaches—viz., four Grosse Mignon, four Early Crawford, and four Noblesse. The largest of the twelve was an Early Crawford, it weighed 9 ozs., and measured 10½ inches in circumference. I also showed twelve Galande, weighing collectively 3 lbs. 12 ozs., and very handsome they were. Everybody said they never saw the like, and I was glad to get out of the way. This may appear egotistical, but it is, nevertheless, true.

Many of your readers do not believe in pot culture. I have seen some miserable failures, but I think I have succeeded in producing quantity and quality. I have a few Barringtons left that will weigh 7 or 8 ozs.

I have sometimes thought that both Mr. Rivers and Mr. Pearson were disposed to exceed the possibilities of the system of pot culture, but I have hitherto had no difficulties, and have realised all and more than I expected.

I have found it necessary to work every day, to watch and tend; but the results have afforded pleasure and profit. Not only do my trees afford recreation and amusement to myself, but to a large circle of friends, and to many strangers who happen to hear of my pets.

With your permission I may at some future time have a word to say to amateurs, and any who purpose to try for themselves. Should any of your readers be visiting Ryde, I shall be happy to show my house and trees. Mr. Redman, fruiterer, opposite the pier gate, Ryde, would direct to my residence.—C. COLENTUTT, *Homelands, Ryde, Isle of Wight.*

ACER LOBELII.

ME. NEWTON having in a late Number of THE JOURNAL OF HORTICULTURE drawn attention to that fine American tree Acer macrophyllum, allow me also to describe another fine Maple, Acer Lobelii (Tenore), which, although introduced into England about the same time as Acer macrophyllum, is still very rarely to be seen in pleasure grounds, and almost unknown, except in a few of the leading nurseries.

The Acer Lobelii was first brought into notice and critically described as a distinct species about half a century ago, by Professor Tenore, of Naples, in his "Flora Neapolitana." More recently Mr. George Don, in his edition of "Miller's Dictionary of Gardening and Botany," by some oversight not easily accounted for, makes Acer Lobelii and platanoïdes the same species; while Mr. Loudon, in his great work the "Arboretum Britannicum," puts it down as a variety of Acer platanoïdes, but with a remark that "it is one of the most beautiful Acers in cultivation." No two species of Acer, however, can be more distinct or dissimilar in habit than Acer Lobelii and platanoïdes, for Acer Lobelii has an upright-growing head, rather thinly furnished with branches and branchlets, and glossy pea-green shoots, striped somewhat in the manner of those of Acer striatum, or the Snake-barked Maple of America. The shoots are also more remotely clad with leaves, which are seldom more than 3 or 4 inches broad, but thick in texture, glaucous green in colour, and bluntly lobed; while those of the Norway Maple (platanoïdes) are dark green, thin in texture, acutely and distinctly five-lobed, and 6 inches broad. Again, the Norway

Maple only forms a medium-sized tree, with a dense, leafy, spreading, round, bushy head, full of irregularly extended branches and small spray of a dark brown colour when matured; while the Acer Lobelii, on its native mountains in Naples, forms a large erect tree, with not very many branches or much spray, but with rather stout, erect, straight, glossy, pea-green shoots, more or less streaked with white. The leaves are very slightly heart-shaped at the base, quite smooth, thick in texture, shining above, and of a glaucous green colour, with the lateral lobes of the leaf less developed and abruptly pointed.

The Acer Lobelii is said to have been introduced by Lord Coventry, and first planted at Croome, his lordship's seat near Worcester, where, according to Mr. Loudon, the finest specimen of the tree in England was to be seen in 1839, it being then 20 feet high, and in some years it bore seeds.

The tree is perfectly hardy, of rapid growth, and one which certainly deserves to be planted in all pleasure grounds or parks, on account of its stately appearance and cheerful aspect. It was first introduced into England in the year 1826, according to Mr. Sweet.—GEORGE GORDON, A.L.S.

RED SPIDER ON VINES—PRUNING FILBERTS. CALCEOLARIAS DYING OFF.

I HAVE at the back of my viney some Peach and Nectarine trees, which are much infested with red spider. Although the crop has been gathered for more than a fortnight I have been afraid to syringe, or use any means to destroy the insect, as my Grapes are now pretty well ripe. I now perceive that it has commenced its attacks on the leaves of my Vines, as likewise on some Capsicums which I have growing in pots in the same house. The latter I have dipped in Gishurst compound at the rate of 1 oz. to a gallon of water, but should be glad to be advised by you what to do to my Vines and Peaches. As the Grapes are now ripe, I am afraid to syringe them with the mixture.

How should Filberts be pruned to keep them dwarf?

My Calceolaria Kayi keeps dying off, even plants that have been in and flowered all the summer before. I have a bed of amplexicaulis by the side of them, of which I have not lost a plant. Could you tell me the cause?—NORTH DEVON.

[Your case is an instance of the great care that is requisite when Vines, Peaches, &c., are grown in the same house. You may be thankful that the Grapes were almost ripe before the spider from the Peach trees commenced upon them, as that will prevent the flavour being much injured. You can now do little except in the way of palliatives, unless you resolve to go to the trouble of washing every leaf with soap and water, or such a decoction as you name of Gishurst compound.

In the first case we would clear out all the Capsicums, syringe the back wall with Gishurst just high enough up to be sure that not a drop fell on the Vines. Then we would paint every open place on the north wall with a paint of soft soap, water, and flowers of sulphur, and shut up the house early in the afternoon when the sun was still brisk upon it. Then, if there are hot-water pipes, we would coat them over with sulphur and lime, and put a brisk fire on in the evening, and keep the house shut for several nights, giving air, however, early in the morning. These means will act as checks and palliatives.

If you try the second plan, it would be well to remove all unnecessary laterals, and then carefully sponge every leaf, without allowing a drop to touch the bunches. You must rely for completely getting rid of the enemy, on thorough cleaning after the Grapes are gathered and the Vines are pruned, such as syringing the whole house, glass, wood-work, and Vines with warm soap water, washing all with the same with a brush or cloth, not omitting the Vines, painting the latter with clay and sulphur, removing 2 or 3 inches of soil inside the house, watering with water at 160°, and fresh surfacing with new soil, after the walls, &c., have been limewashed. Then, at least the top of the back wall should be painted with sulphur.

In a dull day you could put a fire on and keep the house not quite close, but with only a little air on at the back. We can hardly hold out hopes of your being able to do more than keep the enemy in check until your crop is gathered.

To keep Filberts dwarf and in a good bearing state, you should treat them very much as you would a Gooseberry bush, as they generally bear best on short, stumpy young wood.

It is difficult to tell you why your Calceolaria Kayi keeps dying, whilst amplexicaulis keep well on. The free-flowering at the early part of the season might have exhausted the Kayi, and more especially if the roots had been at all cramped before turning them out. Some of our Calceolarias are also going, but that is solely owing to the drought; as though the stems have had three sprinklings from showers, the roots have had no moisture for more than two months, all the rain at any time not wetting the dusty earth more than the eighth of an inch deep. We presume that you have not had to complain of dryness, because amplexicaulis is the first to suffer from that; and we can suggest, therefore, no other cause but very free early blooming, early cramping of the roots, or a soil deficient in nutriment.]

GRUBS AT THE GREENS.—No. 2.

MANY thanks for your reply to my grubby question in last week's Journal, but as it is only a partial answer, the better half withheld, I humbly ask for the rest. The charge of "heresy" is a serious one against a clergyman, and "The Chaplain," to boot; so that the sooner I recant the better, as it appears that upon the knowledge of the scientific name depends a thorough cure. Pray what is it? Such an appellation does not resemble Butler's account of

"A rhetorician's rules,
Which serve him but to name his tools."

As even troublesome insects refuse to die unless learned cognomens are given to them.

This reminds me of an anecdote of a physician who wrote a prescription (oh, the heretic!) in plain English. The patient died. The apothecary declared that "of course Mr. Dash died, as the doctor did not write his prescription in Latin." Vulgar "Leather-coat" shall die by an old dinner-knife, but in his prior scientific stage he shall die by whatever sprinkling process you kindly state. I ask on public as well as private grounds, for if next year the grubs increase, the family grub in many a house will painfully decrease. The benefits of a right belief are always great, so I am no longer a heretic, but in this, as on every other point, an orthodox—WILTSIRE RECTOR.

P.S.—I fear I do not always write plainly, thus I wrote in my last contribution on this subject, "fat yellowish green grub," not flat.

[Our indignation is calmed, and we shall at once surprise our correspondent by informing him that the parent of his grubby marauders is no other than the "Daddy Long-Legs, *Tipula pratinus*. The females are now depositing their eggs in the soil, and this is prevented by sprinkling a mixture of soot and gas-lime over the surface of the ground where Cabbageworts or Lettuces are to be planted.]

THE TRIAL BEDDING PLANTS AT CHISWICK.

SOME time ago there appeared in your Journal some very clever little articles on mechanics as applied to gardening purposes. I forgot whether there was an article on the wedge, but if not it was certainly an omission; and I am going now to show you what a useful instrument the wedge is, especially the thin end of it.

In the "Proceedings" of the Royal Horticultural Society for August, September, and October, 1864, there appeared this notice—"Show of Trial Flowering Plants and Fruits at Chiswick, with promenade." Very attractive information to me, particularly as a certain garden ghost some months ago had hinted the difficulty of arriving at a satisfactory knowledge of the vast numbers of bedding plants alluded to by your correspondents, and advertised in your columns.

At Chiswick I arrived after a very hazardous journey by rail from London, and a dreadfully hot walk from the station to the Gardens. Do you know what a sell is? If ever a poor parson was sold, I was on that same Saturday the 27th of August, 1864. "Trial beds"! Now we shall see these Geraniums, Verbenas, &c. "Where are they?" "There

they are, sir?" "What! those little beds with five plants only to each?" "Yes, sir." "And how long have they been planted?" "About five weeks." "But there is no bloom, and some of the beds are not half filled!" "Only five plants of each kind allowed, sir." There was the Roi d'Italie, pretty little Lady Cowper, and coquettish Waltham Pet, a Velvet Cushion, my old friend Lord Palmerston, and defiant Stella. "But how bad you do look all of you! What's the matter?" No answer came; but when I returned home my ghost, a little after dark, whispered consolation, "Never mind, you have got the thin end of the wedge in."—F. W. ADEY, *The Cell.*

HEATING A GREENHOUSE.

I HAVE a greenhouse 24 feet long, 12 feet wide, span-roof, running from south to north. I am about to erect a Cucumber and propagating-house 12 feet square, to join my greenhouse at the north end, and I shall be obliged if you will answer the following questions about heating it.

1st. Will a conical boiler without brickwork answer the same purpose as a saddle boiler?

2nd. Will a round four-inch pipe answer the same purpose as an open one for bottom heat?

3rd. Will a flow and return pipe almost in the centre of my greenhouse be sufficient to keep the frost out? The above to work from the Cucumber-house.—W. F. W., Norfolk.

[1. The conical boiler without brickwork will answer the same purpose as respects heating as a saddle-back with brickwork, perhaps more so; but in a Cucumber-house, if the boiler is inside of the house, it would be desirable to have the feeding aperture and ash-pit door outside, for reasons lately given in answers to correspondents. If the boiler is to be fed inside great care must be used in lighting and clearing away ashes. As respects the latter, if sufficiently wetted there need be no difficulty. If the boiler stands outside of the house there will be loss of heat from its sides, but this might be prevented in a great measure by a wooden case slipped over it, at say 9 or 12 inches distance, the inside of the case being made of a white colour by painting or lime wash.

2. The round four-inch pipe will answer the same purpose for bottom heat as an open one; and if the heat is drier than you like, you can easily make it as moist as desirable, either by evaporating-pans, or throwing water among the clinkers, &c., in which the pipes are packed.

3. A flow and return pipe along the centre of the greenhouse will be effectual in keeping out frost just in proportion to the height of the house and the surface of glass exposed. If the ridge is above 8 or 9 feet from the floor, the sides of the house would scarcely be safe in severe frost, unless means were taken to secure a brisk motion of the internal air. As the pipes are to come from the Cucumber-house at the north end of the span, we would prefer you taking a pipe all round except at that end, placing the pipe not more than 15 inches from the side walls. If the house is lofty, and you have glass at the sides as well as the roof, this would be barely sufficient to keep out severe frost. But for the first expense we would advise more piping, as fuel is saved, and the health of the plants better secured, by never having the pipes very hot.—R. F.]

REPOTTING PEACH TREES.

THE best time for potting Peach trees is as soon as the fruit is gathered—*i. e.*, if the roots are in a healthy condition and growing in suitable soil, in which case do not disturb the old ball, but merely use a larger-sized pot, and make the fresh soil pretty solid with a blunt stick. If the roots are not in a good state defer the potting till the tree shows signs of shedding its foliage, then shake the roots free from the old earth, and repot the plants in more suitable soil. Never repot all your trees in one year, as there is always a slight risk of losing the crop of fruit the year following. Peaches appear to bear better when the pots are filled with roots. Potted early, the risk is very small, as the trees at once make fresh roots. After the fruit is set, and as big as horse

beans, take two parts of horse-droppings and one of malt dust, and place an inch or two of the mixture on the surface of the soil, and renew it when the fruit is half grown. When the malt dust is mixed with manure it should be used at once, as if it remains in a heap it quickly ferments, and produces a very disagreeable smell.

[The above is in answer to the queries of a correspondent whose letter has been mislaid.]

FOUR DEGREES OF FROST, AUGUST 25TH.

SUCH is a fact! In the morning everything out of doors had the appearance of a winter's morning. Many plants were frozen hard and stiff. The Dahlias are black and quite done for. Dwarf Kidney Beans and Scarlet Runners are very much cut up, but not quite killed. The Perilla has suffered much, and Love-lies-bleeding is very much injured. The Perilla is certainly the tenderest of our bedding plants, as ours was very much disfigured by the frost we had here on the 1st of June—viz., 4°. The wind has been north for some days past.

On the 24th the thermometer was down to freezing-point, and on the 25th 4° below it, on the 26th 1° below. It is now, about 7 P.M., the 27th, and there is every appearance of a sharp frost to night.

Has any weather prophet foretold this frost, or the weather in general of the past summer? Everything here is suffering, especially the pastures, for want of rain. We have been obliged to water thousands of Rhododendrons to keep them alive, or many must have died. I am told that Potatoes that were healthy and green before the frost are now black and laying down flat. I never saw nor heard of such a frost in the month of August before.—HENRY COOMBS, *The Gardens, Chetwynd Park, Newport, Shropshire.*

P.S.—I have waited till this morning's post to report upon the night's frost, and I find the thermometer indicates 4°. Last night I covered our Azaleas to protect them, as they showed the effects of the previous frost at the points of the shoots.—H. C., August 27th.

ON the morning of the 25th, the thermometer in the neighbourhood of London indicated 2° below freezing; and at Malton, in Yorkshire, we learn from the *Times* that there was ice the thickness of paper on three mornings of the same week, and that Dahlias were frost-bitten in low situations.

LESSONS TAUGHT BY THE PRESENT DRY SEASON.

FROM the present dry season may be drawn some useful lessons, and the value of these will be greatly enhanced if they are carefully noted now and acted upon judiciously hereafter.

I am the more desirous to draw the attention of your readers to this subject, because I have noticed in various places some of the finest displays this season that the eye could rest upon, although this is a year of marked and unusual dryness. This, then, must be one useful lesson which will serve to teach us that, in spite of a scorching sun by day and a frosty air at night, there are ways and means to secure a floral display.

We shall gain another point by considering how this is brought about, and it is chiefly by a good supply of water about twice a-week—not a mere dribbling from the rose of a water-pot, or a gentle bath from the hydropult, but a thorough wetting through the soil to at least the depth of 6 or 8 inches. How this is to be accomplished may be learned at Kew or Hampton Court. There the beds are not raised, but, on the contrary, instead of sloping from the centre to the outside, they rather slope to the centre, but only just sufficiently to secure every drop of water which falls upon the bed from being wasted. I am aware that an objection can be raised to this form of a bed in a retentive soil should a wet season set in, but this is to be immediately overruled by what ought to be a general practice—namely, deep trenching, the effect of which has never been so clearly demonstrated as in the present season.

As all have not had an opportunity of seeing the effect of this year's drought upon those public gardens, it is with pleasure that I record my humble testimony of the splendid condition of the gardens at the Crystal Palace, at Kew, and at Hampton Court. Their condition demonstrates the ability of those upon whom the management devolves.

One more lesson to be learned there I will bring under notice, and that is the absence with one exception (*Purple King*), of the Verbena as a bedding plant. I must not be understood to say that it is altogether banished from the flower garden, but a visitor at the Crystal Palace or at Kew cannot fail to notice that it is not so much used there as in times gone by. With me the Verbena is an especial favourite, therefore it must not be inferred that I make this comment purposely to lower it in the estimation of others; but my own observations justify me in saying, that near the metropolis the Verbena is often a failure, and as too many to their sorrow will tell us, it is usually so infested with thrips that it is more often than not a source of much disappointment.—J. C. CLARKE, Wimbledon.

BEDDING GERANIUMS.

(Continued from page 167.)

THE modes of managing bedding Geraniums being endless, I shall only treat of one more, and that is how to dispense with potting in the spring treatment of autumn-struck cuttings. With this object in view they should remain in the cutting-boxes until the beginning or middle of April, and a pit or frame filled with ashes or any kind of rough material to within 1 foot of the glass, or failing that, a turf pit to be covered with some old lights, should be in readiness to receive the plants. We then provide, or rather have at hand before we require it, some sphagnum, but if that cannot be procured, the moss found abundantly in some woods will answer admirably. Having a heap of compost before us, another of sphagnum or moss on one side, the box containing the plants on the other, and some matting cut into two-feet lengths, wetted, and hung up in a convenient place so as to be easily reached, we then take a lump of moss, draw it out so as to be the width of both hands every way, and lay it on the potting-bench on a piece of the matting. We next place a little soil on the moss, and then, having taken the plant out of the box, place it exactly in the centre of the moss bed, and put a little more soil round it. We then close the moss neatly round it, and bring the strip of matting over the top, by the stem of the plant, down again under the ball, I will call it, and up again, twisting and turning it about until both ends are just long enough to tie, when we fasten them with a knot that will draw the closer the more the moss swells after watering. We have then a Geranium wrapped in a moss coat, just as nursery-men wrap the roots of their choice shrubs for travelling, with this difference, that we put a little soil within the parcel in addition to that adhering to the roots.

Each plant when mossed is placed in a riddle, and when this is filled the whole are taken to a frame, or pit, and we pack them closely together, and spread about half an inch of fine soil over the moss between the plants. In this way we go on, watering them after the surfacing of soil till we have the frame full.

After the plants are placed in the pit nothing is required but to keep the frame close for ten days, protecting from sun by day and frost by night, and afterwards to give abundance of light, air, and water when necessary, with frequent sprinklings overhead. By the last week in May or first week in June they will be all that can be desired, the moss being one mass of white roots, and they may then be planted in the beds. The matting is, of course, rotten by this time, yet the plants move with a splendid ball, and the roots are not matted by running against the inside of a pot but present innumerable mouths ready to lay hold of the new soil without deviating to the right or left, whilst the roots of plants under pot treatment have to change their course, which they sometimes do tardily, as the sickly foliage too plainly testifies.

As to old plants, which are preferable to young, from their blooming earlier, besides being larger and more generally effective, I will now offer a few remarks on preserving them through the winter.

Most of us desire to prolong the beauty of the flower garden to the latest possible period; but care should be taken lest this be not overdone, especially when the plants employed are required for another year's ornamentation. Sooner or later in October we must prepare for frost; but as no set time can be given, it is better to take up the plants a few days too soon than wait until they are hung with crystal drops, and their fleshy leaves have a glassy aspect. It is too late then, for, cover them as you please, the stems will rot when placed in heat. The plants may, it is true, be saved for a time by being protected at night by hoops and mats, or canvass, taking off the covering during the day; but to do well they should be taken up and potted, or otherwise placed in safety, before the occurrence of frosts of sufficient intensity to injure them. I have found on a mean of the last two decades, that the 10th of October is the latest period at which Geraniums can be trusted outside with safety.

Presuming the plants to be planted out in the bed, we take them up with as much root as possible, not that a large root is desired, but when taken up carelessly we are apt to split the stem leaving a ragged fracture which admits wet, ending in the decay of the stem and the loss of the plant. It is also undesirable to split the top by careless and rough handling, for being very succulent the branches are easily split off at the points where they spring from the stem. In short, care should be taken to injure them as little as possible. Choose a dry day for taking up, and this done and all being in readiness for potting, we have to distinguish between variegated, tender, and rather small-growing kinds, and those of strong and vigorous habit. After this, we trim the roots in the first instance, cutting them in with a sharp knife so that a year-old plant may pass easily into a 32-sized pot if a small grower, or into a 24 if strong, proportioning the size to the size of the plant. The roots of all may be cut in to within 3 inches of the root-stem for plants that are not required large; but where large plants are desired it is not necessary to reduce the roots so much, but to proportion the reduction of the root to the size of the pot which the plant requires. After reducing the roots, which must be done in proportion to the size of the head to be left, it becomes necessary to cut in the latter. This is done by removing the old shoots and thinning out those remaining, so that they may stand clear of one another. We take away the old branches because they seldom put out a profusion of shoots, and those which are produced by them are weak, and as such undesirable. The young shoots left, on the other hand, produce numerous shoots, and for that reason are preferable to old shoots. They, therefore, require the same treatment as to cutting-in as Pelargoniums after blooming, distributing the shoots, and shortening them so that an even-headed or well-shaped plant may be produced in the following season. The shoots left, having been cut in to within 3 or 4 inches of the old stem, will have few if any leaves upon them, but this is of no moment (though I confess that I like them with a few leaves); and the plants should then be potted in any light good loam with a little sand intermixed. The soil should be in a moderately moist condition in order to obviate the necessity of giving water for some time. They are then to be placed in a house from which frost and damp are excluded, it being immaterial whether they are in the light or dark for a month or six weeks, by which time they will have pushed and will require light and water to sustain their vitality. Probably the young shoots will have a blanched appearance, but they will become green on exposure to light. During winter the plants will merely require frost to be excluded, and but little water will be needed. In February or March they will be growing freely, and must have more water; and in April if room can be spared, they may be potted, and afterwards treated the same as the cuttings potted in the spring. This treatment, it must be borne in mind, is only suitable for the stronger-growing Scarlets or others of free growth; most of the Variegated, and some of the less vigorous kinds, requiring a different mode of treatment, which I shall notice presently.

Some think potting old plants in autumn a waste of room, considering it merely necessary to pack them closely in poor earth in boxes, cutting away all the leaves and the large disproportionate heads, without reducing the roots

so much as for potted plants. Some place the boxes so filled with plants under shelves and stages in houses, or in cellars, and sometimes, but rarely, in houses where light and air can be afforded. When placed under stages one-half the plants perish by the drip of the plants above them. They are liable to wither in a dry cellar, and to damp-off in a wet one; and boxes in a house of any kind, unless made neatly and well painted, are eyesores. I have hitherto considered that there are conveniences at hand to do without these makeshifts, and that any one interested in a garden can derive pleasure from seeing the places where the supply of plants is kept to furnish the flower garden in summer.—G. ABBEY.

(To be continued.)

CULTIVATION OF THE MELON.

(Continued from page 153.)

HEATING by means of hot-water tanks is an admirable means of supplying bottom heat to Melons. Fig. 9 is the

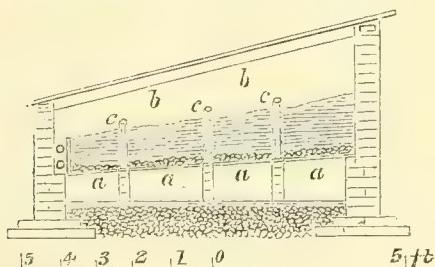

Fig. 9.

section of a pit well adapted for the Melon or Cucumber. *a, a, a, a.* Are compartments of a cemented tank containing about 6 inches deep of water, separated from each other by cemented brick walls one brick thick. This tank is covered with slates, which are laid without mortar on the division and side walls of the pit. Where there is a rather large hole between the slates advantage is taken to place an ordinary three-inch drain-pipe with one end over it, or a still better plan is to place these drain-tiles over holes made by taking the corner off a slate where it rests on the division-wall, and 2 feet apart. A few inches of rubble placed on the slates, and a sod grass side downwards upon it, will prevent soil getting down to openings between the slates; and whilst allowing the superfluous water of the soil to pass away, will also prevent the steam from the tank rising too much through the rubble into the soil, and making it sour or sodden, at the same time the advantages of a moist bottom heat are secured. The drain-pipes standing on end pass through the soil into the above space, *b, b,* and through

front. The ground plan, *A*, shows the circulation of the water, which enters the tank at *a*, and makes its exit for the boiler at *b*.

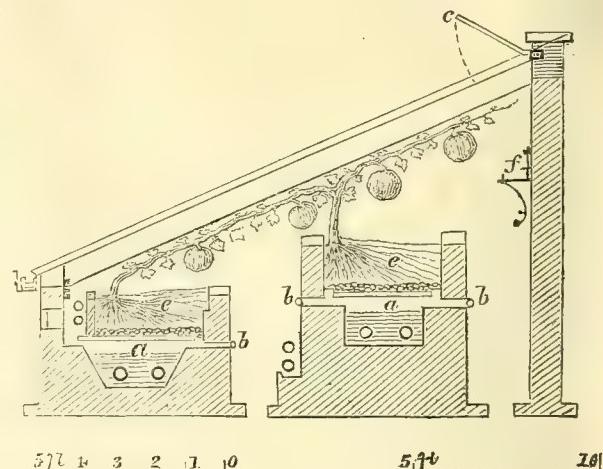

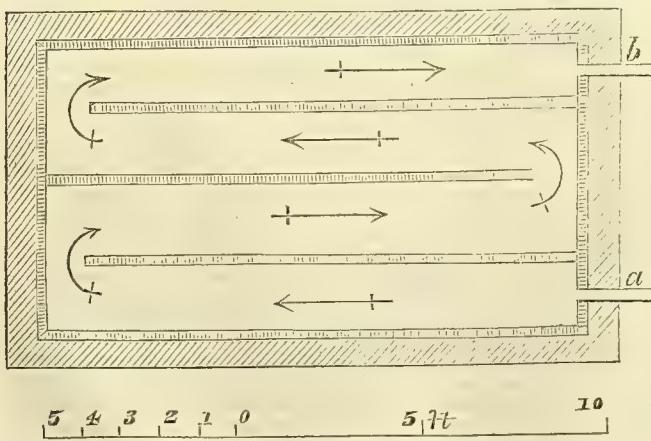

Fig. 10.

Fig. 10 is a lean-to house about 12 feet wide inside. The pipes for bottom heat are in a tank, *a, a*, which is about three parts full of water. The tank is covered with flags or slates, but so placed that an opening 2 inches wide is left between them and the walls on which they rest. This allows the steam to rise; and openings being left, or a piece of 1½-inch pipe let through the walls of the pits, one end communicating with the tank and the other with the house, the atmosphere can be made moist, and when not wanted the pipe may be covered with a cap at *b, b, b*. A moist heat and an increased temperature is therefore obtained. The house is ventilated at top, *c*, and in front by means of boards hung in the centre, and which can be opened much or little at pleasure. The air entering there is warmed by the hot-water pipes before it reaches the plants. *e, e.* Are spaces for soil over the tanks. There are two pits and two sets of plants as shown, one occupying the half of the house in front, and the other the upper part, and there is a shelf for plants at the back, *f*.

Fig. 11 is a section of a pit useful for growing almost any kind of plant. Like the preceding, the pipes for bottom heat are in a tank of water, *a*; but they might be kept dry in a chamber, or be surrounded with rubble. In front is an open cavity in the wall, and by means of a wooden ventilator air is admitted at *b*, becoming heated before it reaches the plants. The small lights are made to open by lifting

Plan A.

them rises a nice moist heat, which can readily be kept down by placing a flat piece of slate over the ends of the pipes, *c, c, c.* In addition to the heat ascending by the drain-pipes, top heat is furnished by two four-inch hot-water pipes in

up with a crank, &c. There is space for soil at *c* over the tank, a shelf at back for plants, and a walk at back for convenience. The Melons are trained to a trellis.—G. ABBEY.

(To be continued.)

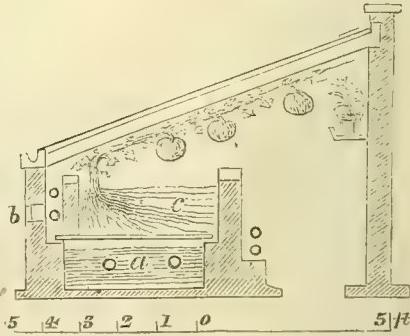

Fig. 11.

AN ELEGANT MULCHING FOR ROSES.

In a full south aspect in front of my house I have several choice Roses, which are trained on wirework (galvanised). Notwithstanding copious and continued waterings, they have all suffered from the extreme heat of the sun, except two, which had the Musk plant growing on the surface of the soil. This appears to have acted as a most beneficial mulching; in the watering given to the Roses the Musk has luxuriated, and the Roses have remained free from the attacks of the aphid or red spider, and rewarded me with rich blooms, while their companions unmusked have struggled unsuccessfully with their insect enemies, and have disfigured rather than ornamented the front of my house.—T. S.

[Is the smell of Musk offensive to insects?]

PACKING ORCHIDS FOR IMPORTATION.

Can any of your correspondents, who are in the habit of importing Orchids, inform me what is the best mode of packing the Aerides, Vandæ, &c., from India, in closed cases. A friend offers to collect for me, but glazed or Wardian cases are not available. If packed in charcoal dust would they not do well?—ORCHIDOPHILUS.

[Knowing several parties who are desirous of the same information, we insert this inquiry prominently, and shall be obliged by any information on the subject.—EDS. J. OF H.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

SUCH ground as is now becoming vacant should be trenched-up as roughly as possible, manure being applied if necessary. This should always be done as soon as the crops are off, whether the ground is wanted again immediately or not, as it is an absolute loss of fertilising properties to allow it to lie unturned. Gravel walks must come in now and then for a share of attention in weeding, rolling, &c. *Cabbage*, plant the principal crop of spring *Cabbage* on ground well manured as previously directed. The East Ham is a good variety for standing over the winter, it is not so apt to run in spring as most others. Prick out into beds a few inches apart, a large quantity of *Cabbage* plants which have just expanded their first two rough leaves. They will be required in spring. *Cauliflower*, young seedlings must not be allowed to stand too thick in the seed-bed. The thinnings may be pricked out thinly, and they will make good stocky plants. The watering of *Cauliflower*, *Broccoli*, and *Celery* must be diligently followed up, for it was never more necessary; near London we have not had a good soaking of rain for many months. Where deep trenching is practised its effect is very perceptible in the luxuriant growth of these vegetables. *Endive*, the July sowing may now be pricked out on a warm border, and as the early plantation attains a proper size the plants should be tied for blanching. *Lettuce*, make the last sowing for the season of Brown Cos and Hardy Green on raised beds of light soil, where they may remain till spring and be planted out to succeed those that are transplanted this autumn under walls and similar situations. *Scarlet Runners*, the large pods should be picked clean. These often give over bearing prematurely through the exhaustion occasioned by suffering the pods to go to seed. *Spinach*, see that it is properly thinned and the surface stirred.

FRUIT GARDEN.

Fig trees out of doors should be liberally supplied with water, if no rain falls, to enable them to swell off the late fruit. Give a final nailing to all wall trees, that there may be nothing to obstruct the perfect maturation of the wood. Vines out of doors should have every shoot of useless wood removed, and the branches laid in close to the wall. It is a somewhat nice point to know when to gather the respective fruits, some being best at one stage of the ripening process, and some at another. As a general rule fruits of a precocious character and which ripen rather rapidly, and those also possessing some aroma, should be gathered somewhat underripe; whilst those which ripen with difficulty, which are long

in colouring, or which are scentless should remain much longer on the trees.

FLOWER GARDEN.

Neapolitan Violets which were parted and planted out in spring should now be carefully taken up with good balls and removed to a frame or pit for flowering during winter. The soil most suitable for them is well rotted turf; but sweepings of roads or any light soil will answer. Sweet Peas, Dahlias, and other plants requiring tying up should now be attended to before they are destroyed by winds. Climbers on walls should again be pruned and nailed if they require it. Mow, sweep, and clean grass lawns: hoe and rake borders during this fine weather, and destroy all weeds before rainy weather sets in. Still continue to propagate showy and choice herbaceous plants by cuttings and division of the roots, and seedlings of late-sown perennials may still be pricked out with advantage. Pot off a goodly number of the different varieties of Brompton, Giant, Queen and Intermediate Stocks. Continue to plant out Pinks, Clove Carnations, and rooted cuttings of hardy herbaceous plants into nursery-beds. See that plants already established in beds are kept in a state of health and vigour by stirring the surface of the soil. Look now and then at the late-budded Roses and loosen the ligatures. Chrysanthemums out of doors should be carefully staked; if against a wall, where they thrive better, they should be trained while the succulent shoots will bend. Put in three or four cuttings in a 48-sized pot for blooming late.

STOVE.

Winter-flowering things should now receive extra attention, as also those succession flowers which have been retarded. Nothing but a light situation will be suitable after this period. Those who are compelled to grow such stock in the shade of late vineeries or other forcing-houses must rest contented to endure a partial failure. Let the Begonia family be duly estimated in this respect. The *Euphorbia jacquiniae-flora*, if propagated early and frequently pinched back, will now be dense bushes. They look best three in a pot. Of course, such plants as the winter *Gesneras*, *Achimenes*, &c., will not be forgotten.

GREENHOUSE AND CONSERVATORY.

Although many persons may hesitate in the work of introducing the house plants while the promise of a late summer is before them, nevertheless it is dangerous to trust anything to the weather at this period of the year. Cloudless days are very delightful, but it not unfrequently happens that they are succeeded by clear nipping frosts at night: therefore the work of taking in plants should proceed uninterruptedly. Let the condition of each be examined, and defects in the soil or drainage of the pots be at once remedied. Clear off moss, remove insects, and replace stakes. The ordinary precautions for obtaining a supply of common flowering plants throughout the winter months should be progressively continued, *Mignonette* sown, *Hyacinths*, *Tulips*, and other bulbs potted and plunged—about equal portions of good loam and decayed leaf mould, with silver sand, will be the best soil for these if for forcing; but well-decomposed cowdung must be substituted for the leaf soil when the bulbs are intended for late flowering. After potting them, place them on a dry bottom, and cover the pots 2 or 3 inches deep with old tan or ashes, preserving them at the same time as much as possible from heavy rains. Under this treatment they will fill their pots with roots, and be in readiness for forcing when wanted. Pinks for forcing must be encouraged, and *Cinerarias* duly attended to. Roses in pots should occupy a fair share of attention. Young plants may yet receive a shift, and manure water may be applied to plants in activity. Where valuable stove plants have to be kept in the conservatory while in bloom, they will require careful management to prevent their being injured by damp; and they must not be overwatered at the root, as stove plants are soon injured in a low temperature if kept too wet. Give air freely on bright days, but if the house contains many stove plants it will be advisable to shut up early in the afternoon, so as to retain a little warmth for the night, and in the event of wet cloudy weather setting in, it will probably be found necessary to use a little fire heat to dispel damp and preserve blossoms of tender things, and this should be seen to before handsome specimens are disfigured.

or ruined for the season. Keep everything as clean and neat as possible, removing decayed leaves and flowers, &c., immediately they are perceived.

PITS AND FRAMES.

If previous directions have been attended to, the propagation of next season's bedding stock will by this time be well advanced, and where, from the pressure of other work or any cause, this is not the case, every possible dispatch must be used while the weather is favourable for such work. Continue to put in cuttings of new and scarce plants. A close frame without artificial heat will answer to keep them in at present.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

REMOVED the dried-up haulm of Peas and Beans, unless where we wished them to remain as a shade to undercrops. We have had a skiff of a shower or two on Wednesday which refreshed the foliage, but did nothing to moisten the ground. We have trenched-up a piece where Peas had been grown, and though stiff soil we found it very dry for 18 inches in depth. We have turned out lots of winter stuff with balls, giving a little sewage water round each plant, and then firming well and covering with the dry earth. They will have the chance of rains, and must be watered when we can obtain it. It is difficult to make people attend to these little matters even as respects planting. The above mode costs a little more trouble than putting the plants in in the usual way, and then soaking them well from the surface, but a pint of water would do more good in the one case than three pints in the other. In the first case, the moisture is retained immediately about the roots and the soil is not cooled by evaporation. In the second case, the plants are checked by a diminished temperature, and the water you give soon mounts up into the arid atmosphere. Planted Lettuces, Endive, &c., in a similar way. Pricked out the most forward Cabbages for the winter that they may be lifted and turned out with balls as soon as the ground is ready. Watered a succession-sowing in the seed-leaf, strewed them with ashes, and shaded to keep out the heat. We are glad we planted a lot of Lettuces close to the foot of the north side of a wall. They are succeeding those under the shade of Apple trees. Unable as we have been to water, none but sown Lettuces could stand any time in the open garden.

Raised and spread out a portion of the Onion crop—a good crop notwithstanding the drought. We hear much said about housing them securely. If kept dry they will stand any amount of cold. We have never seen them keep better than when tied up in strings and hung up in an open shed. No frost seemed to injure them so long as they were kept dry; but if rain or snow blew in on them and melted, and a sudden frost came, they were apt to be a little injured. We often wish we could use them with impunity, but the use of one will taint all our wearing apparel for a week. We have known several very strong old men who attributed their strength after they had seen seventy years and done much hard work, to the free use of Onions. We have seen some of these men slice off raw, with the greatest gusto, some three or four large Onions along with their bread and cold pork for dinner, and declare it was a dinner fit for a Prince. As for that, we have no doubt that the hungry ploughboy who, swinging on a gate, slices off his cold bacon and bread, whilst his team are having their lunch, eats with a relish that the rich man rarely enjoys when partaking of the most richly-seasoned dishes. We have long been convinced that a good hot raw Onion is a capital thing for labourers who work out of doors, and who rarely have a good hot dinner. Good people should think of that before they show that they are annoyed by the Onion odour which generally accompanies their use. We have known cottagers troubled as to where they could house their Onions. Let them be assured that all that is wanted is to keep them dry, then no frost will injure them.

From Celery we removed the shading of branches, and we are surprised how well, on the whole, it has done without watering—not a great deal behind some good Celery we lately saw that had been soaked once a-week. We cleaned

all that had been put out—pretty well enough for our use—by removing every bit of sucker, and then placing a little earth close to the stem. We are behind our usual time in earthing-up, and have only done a part of one bed. Our kind, the White Incomparable, if each head is tied after clearing away the suckers, needs but little earthing-up. We have a small bed, thick together, well blanched for soups, and for an occasional bit of cheese; but good heads will need something like three weeks. But for scarcity of water we would have had it in the beginning of this month, or much earlier. We have just managed to give our four large beds a fair watering with sewage, keeping it off the leaves, and will follow with about an inch of fine soil to keep the moisture in. It will soon fly off through the foliage, however, and that will necessitate shading, if the heavens do not give us a good watering. We will plant out a little more with good balls so soon as dripping weather comes. For want of wet, though we gave a little water to the drills before sowing, we seem to wait a long time for Spinach and Turnips coming up.

No weather could be better for hoeing, to keep the surface open, and to kill all sorts of weeds. We use the words "all sorts" advisedly; for, if not all, the greater portion of the worst weeds—those worst to conquer—may be thoroughly eradicated by a persistent use of the Dutch hoe. "At them, always at them!" however, must be the motto. Keep this motto in view, and many weeds whose roots are difficult to eradicate will succumb, the roots decaying when the top is prevented giving them the benefit of any reciprocal action. We have proved repeatedly that Nettles may be destroyed, not by digging up their roots, but by continually cutting off the tops when not more than an inch or two in height.

There can be no worse weed to destroy than the large white-flowering Bindweed, that soon threads the ground with its cart-rope-like underground stems, and the smallest portion of which will grow. We once had a corner thoroughly overgrown with it. Take up a spadeful of earth, and there would be fully half a spadeful of these roots, called here by a term anything but pleasant to ears polite. We let it alone for a bit, then used a scythe over it, removed what was cut to the burning-heap, placed a foot of short grass over all, and let it remain six weeks. On digging it up in the winter not a root was visible, though openings in the soil, of the size of tobacco-pipe stalks, told clearly where they had been. There were some Roses and other plants round this corner, and there enough was left for a future stock.

The above was a summary way of eradicating this troublesome customer, which from occupying a foot would soon if left alone occupy a whole garden. We have several times proved that this intruder can be equally successfully disposed off, if there is constant war between it and the Dutch hoe—that is, if it is cut, and cut, and cut again as soon as it puts out a modest shoot of from 1 to 2 inches in length. This cutting continually at the top seems thoroughly to paralyse and kill the large roots, full of vitality as they otherwise are.

We lately saw a fine old garden in this neighbourhood, and not a vestige of this weed to be seen anywhere in its seven acres. We knew that for years the garden was overrun with it, for it had been pretty well left to take care of itself, as all the keeping it had was merely a pretence, owing to a deficiency of labour power, though the man who superintended it wrought so hard from "early morn to dewy eve," that when one shook hands with him you might well fancy you held a rough iron file in yours. Well, we are glad to see that the fine old place looks now as if it meant to take its right position; but among all the improvements wrought by the present superintendent, nothing pleased us more than the seeming absence of this pest, which threatened to monopolise the whole place. The good man and accomplished gardener did not mind telling us as a secret how he conquered this enemy, forgetting, no doubt, our inability to keep anything of the sort; and the pith of the secret, and consequent remedy, was just this—keep cutting it up with the hoe whenever it shows itself above ground; if the weather is sunny all the better. This quite corresponds with what we, too, have experienced, and numbers may be thankful to know that this pest, the *Convolvulus sepium* of Willdenow, we believe, and the *Calystegia sepium* of other authors, may be quite destroyed, and by a less troublesome

process than digging and forking over and over to discover every bit of its white stringy roots.

We have not quite the same amount of experience with another trailing, flesh or pink-flowering little Bindweed—the *Convolvulus arvensis*, which produces long knotted roots; but from what little we have tried we feel convinced that, too, could be eradicated by constantly cutting off the top as soon as it appears above the ground. This seems to grow more rapidly after cutting than the large-flowering white *Convolvulus* above referred to, and to delight as much in dry loose soils as the white strong-growing one does in soils that are moist, close, and rich.

The continuous cutting of this trailing *Convolvulus arvensis* is of all the more importance, as the smaller roots are traced with more difficulty than the larger white roots of *Sepium*. The latter, though ruinous to a gardener, is a beautiful object with its snow-white blossoms on wild hedges and woodland scenery when in company of the *Clematis* and *Honeysuckle*, and some authors say that the roots may be used instead of scammony, as a stimulating cathartic. The less we see of such a plant in the garden, however, it will be the better for us. Some years ago we were presented with a hardy kind with white flowers as large as a saucer, and beautiful it looked; but though placed against a wall, and the root confined to a large pot, the shoots soon layered themselves, made bushels of large roots, larger than *Sepium*, and threatened to monopolise the whole wall and border, until we saw the necessity of destroying it, or carefully watching it.

Gathered a nice lot of ripe Tomatoes that had been trained against the back wall of an earth-pit. Ridge Cucumbers and Gherkins were planted in front of them, and after having gathered a number for pickling we were forced to let the leaves of the Cucumbers become like tinder for want of the ability to water them. Most of our Vegetable Marrows are going off from the same cause, though it is no great loss, as, after this month, they are rather cold matters to have much to do with, unless treated something in the way that flint soup must be to make it at all agreeable. Gathered also a lot of ripe *Chilis* and *Capsicums* for Cayenne. We used to wonder how *Chilis* were most in request for that purpose, as, so far as strength is concerned, there seems little difference between them and the generality of *Capsicums*. We think, however, the reason might be that, bulk for bulk, there is more outside skin in the *Chilis* than in the generality of *Capsicums*, and also that on the whole it is firmer. In most private establishments we believe that the Cayenne is made from the skins dried and pounded. We think that the seeds are hotter and stronger than the outside covering; but they are seldom used, or other colours of *Capsicums* except the red, as that would interfere with the red colour of the Cayenne. Why should not all be ground together, or the seeds and their outer integument kept separate? So long as Cayenne must be red there will be adulterations, just as pickles must be green, and, therefore, to a certain extent poisoned. The purchaser in such matters is pretty well as much to blame as the manufacturer, who makes to sell, and therefore must please the tastes and even the prejudices of the buyers. Would some friend tell us if there is any reason, except colour, why the seeds of the *Capsicum* tribe should not be ground into pepper?

Owing to a press of other matters and a scarcity of material, we deferred from day to day, and, therefore, rather long, making up a piece of a *Mushroom-bed* in our open shed. To make the matter worse, we mixed rather more of fresh droppings with some old dung than we ought to have done when haste was the object, as the mixture heated too much to enable us to spawn it quickly. In all such matters instead of mixing, it is better when quick work is wanted, to build in separate layers of old and new must be used. A fine heat may be obtained and lasting from using old and new tan in layers; but an excessive and fiery heat may easily be had from mixing them together, a matter of some importance to those who use tan for bottom heat. Owing to the reasons stated above, we were some three weeks without *Mushrooms*, but as our superintendent of the kitchen had preserved some buttons the want was not much felt. The first piece has now for some weeks been in excellent bearing, and the *Mushrooms* are firm and fleshy, independently of the heat, which we attribute to the shady place and a free current of air over the bed. The second piece is spawned,

earthened, beaten down, and a little hay sprinkled over it to prevent its cracking, and we have just put in dung for a small third piece, the droppings being rather fresh and mixed with turf soil. We have also made a good number of bricks for spawn, as described last season, and set it in an airy place to dry before spawning. The bricks this year are only about $1\frac{1}{2}$ inch thick, as we found such better every way as respects finishing than thicker ones. These we will spawn when dry enough. Previously *Mushrooms* were such an everyday affair that we made a good deal if not the most of our spawn; but for a few beds it will always be best to purchase from one of the commercial establishments which pride themselves on sending out a first-rate article. No doubt the spawn is often blamed, and the materials are blamed when the blame ought to rest chiefly on our inattention. Whatever the materials are, it is our part to vary our treatment according as we find them; and at their earliest stages *Mushroom-beds* need looking at once or twice a-day to see that all is right. Trial sticks are easily felt, and there should be plenty of them.

Our *Mushroom-house* we have had all cleared out, leaving no woodlice if we could help it. Then two days running we burnt sulphur in the house, so that by shutting up every cranny no living thing would have the chance to survive. When the house had stood open a few days to get rid of the fumes of the sulphur, the walls, &c., were all limewashed, to fill up all holes and places of refuge, and when we can obtain some material during the month we will begin making our first bed. We previously stated that we found small beds in succession the best for a continuous supply when the material is at no time abundant.

Fruit and ornamental department much the same as in previous weeks.—R. F.

COVENT GARDEN MARKET.—SEPTEMBER 5.

The supply of out-door fruit is very plentiful, but the size is not equal to what it is in ordinary seasons. Of "rough" Apples and Pears, such as are hawked about the streets, immense quantities come in, and the prices realised are almost nominal. Importations of French Pears are likewise heavy. The best dessert Pears consist of Jargonelle, Williams's Bon Chrétien, Duchesse d'Angoulême, Béurré d'Amanlis, and Louise Bonne de Jersey, of hothouse fruit, Grapes, Peaches, and Plums are abundant, but the supply of Pine Apples is shorter. Very good Figs are now coming in from Jersey. Kentish Cobs have made their appearance, and bid fair to be of good quality, judging from the samples which have arrived. They bring from 60s. to 65s. per 100 lbs. Good vegetables are very scarce, owing to the late drought, and realise high prices. The Potato market is heavy, and the quality is good.

TRADE CATALOGUES RECEIVED.

Sutton & Sons, Reading.—Autumn Catalogue of Imported Flower Roots, Geraniums, Carnations, Fruit Trees, and Seeds for Early Sowing.

E. Verdier, fils aîné, Horticulteur, 3 Rue Dunois, Boulevard, de la Gare d'Ivry, Paris.—*Trade Catalogue of Gladioli and other Bulbs.—Trade Catalogue of Tree and Herbaceous Paeonies, &c.*

TO CORRESPONDENTS.

** Many questions must remain unanswered until next week.

EMIGRATION TO NEW ZEALAND.—“E. W.” would be obliged by any information relative to emigration to New Zealand, and especially whether it is desirable for a gardener.

LOW WAGES (S. R., Kent).—Gardeners' wages, like all others, are regulated by the relative amounts of demand and supply. No combination can compel a master to give 20s. if he can obtain as skilled a workman for 16s.; and he would be able to do so because no combinations can be general. Strikes and unions always end in great privations to the workman, and in his succumbing at last.

BUNSEN'S BURNERS.—“G. S.” will be obliged by our correspondent “A. W. W.” (June 7th), stating where Bunsen's burners are to be obtained, and their price.

YORK FLOWER SHOW (C. Kennaway).—We cannot criticise in any way the statement made by our contemporary.

MASSING COLOURS (Mrs. Osborne).—There is no practical book upon the subject. Many relative papers have been published in this Journal, and we are always ready to criticise and suggest alterations in modes of planting submitted to us for the purpose. We cannot furnish details, we can only point out defects.

CENTAUREA CANDIDISSIMA SERD (*Irish Lady*).—It will grow from seed, and that most freely, but the difficulty is to procure the seed. We do not know of whom it may be procured, in fact we rather think it is not yet in the trade. When you obtain seed we shall be most happy to tell you when and how to sow it to produce plants.

FUNGS IN TAN (*Orchidophilus*).—The fungus complained of is perfectly harmless, though unsightly. It may be destroyed by moving the surface of the tan briskly with a piece of wood whilst it is in its frothy state. Salt will also kill it, and injure the roots of everything it comes in contact with; but nothing is so destructive to the fungus as quicklime.

FEAR SPORES—HAMPTON COURT VINE—WORM ON THE VINE (*Ruby*).—The fronds may be rubbed between the hands over the pot until they become so much dust, and then laid on the surface. It is the dust which the spore-cases contain that produces the plants, and if a quantity of that dust (which is the spores) fall on the soil, it is sufficient without picking off the large brown specks, which as likely do not as do contain spores. The Hampton Court will do well in a cool viney, and so will any of the Hamburghs, except the Muscat and Golden Hamburghs. The Hampton Court is certainly a good variety of Hamburgh, but we consider the Victoria, and Pope's Hamburgh superior to it. We have in the press a book on the Vine, which will be published shortly, and it is likely to suit you. We are obliged by the Nasturtium seeds, which we fear are not sufficiently ripened to germinate if they do we will let you know about this time next year what we think of it.

GRAFTING AZALEAS (W. H.).—We cannot advise you to graft Azaleas in September, but the operation may be performed at that time if the stock be growing, otherwise it is doubtful whether the graft will take or not. The grafts should be inserted in the strong healthy parts of the stem, their age is immaterial if only they be clean and free in growth.

BUDDED MANETTI STOCKS (*Country Curate*).—The bud should not be covered with soil, for the moss is sufficient to keep the stock moist and cause the sap to flow into the bud. You have done quite right to shorten the shoots of the stock, but they must not be stopped too closely, otherwise the bud will be forced into growth, perhaps, late in the autumn, which is a drawback rather than a gain. In spring, after the bud has grown, cover the stock with soil a few inches higher than the bud, this will probably cause roots to be emitted from that part, and you will have a plant fed by the stock, with the advantage of being on its own roots as well. You may take up the stocks budded with tender kinds of Roses, pot them, and winter in a cold frame, or protect the buds in winter from the severity of the weather by wrapping some hay loosely round them.

GRAPES SHRIVELLING (S. R.).—The Black and Grizzly Frontignans are about the tenderest of Grapes. Neither of them will bear heavy cropping without being liable either to shrivel or shank; and for both the soil should have more calcareous matter, as old lime rubbish, bricks, and lumps of stone, than would be requisite for other kinds. In such a season as we have had in the south, watering the borders would be an advantage. In damp summers such Grapes and Chasselas Musqué would be better if the borders were covered with sashes to keep them dry. The Frontignans in pots would have been benefited by weak manure waterings when the fruit was swelling, but as it is now ripening the manure waterings could do little good. If the crop is heavy removing a few bunches might help to keep the rest from withering away.

APRICOT TREES IN POTS (T. L.).—Not only does Mr. Rivers produce an abundance of fine and well-ripened Apricots in pots without these having their bottoms knocked out, but we have so grown them ourselves.

KONIGA MARITIMA (J. A.).—This is the same as Alyssum maritimum and Glyce maritima. The plant is now generally allowed to form the genus Koniga.

FLORIST AND POMOLOGIST (G. K.).—The Autumn Nellis will be described under Graham's Autumn Nellis, it being the desire of the raiser that his name should be associated with it. The Editors would be too glad to adopt the course you desire, but it is not a remunerative one, and they do not see their way to any alteration in the price. If those whose interest it was to have supported the experiment the Editors so liberally attempted had done their duty, the plan need not have been relinquished.

NAMES OF FRUIT (J. M. Sadler).—1, Louise Bonne of Jersey; 2, Croft Castle; 3, Gansel's Bergamot; 4, Ne Plus Meuris. (*P. J. M.*).—1, Ambrosia; 2, 4, 8, 9, 15, Beurré Diel; 3, 6, 16, Uvedale's St. Germain; 5, Poire Figue; 10, Napoleon; 12, Easter Beurré; 13, Norfolk Beating; 17, Ne Plus Meuris.

JACOBÆA LILY HARDY (*Jacobæa Lily*).—You are quite right in your statement that Mr. Beaton, at page 130, vol. i., of *THE COTTAGE GARDENER*, affirms that this Lily “Is found to be quite hardy in England if planted in front of a greenhouse, or in dry earth everywhere, if planted 6 inches below the surface;” but he goes on to say that it never flowers unless taken up in autumn. We really do not perceive what information you require more than Mr. Beaton has recorded.

CLOTH OF GOLD GERANIUM FAILING (*A Constant Reader*).—We grow this Geranium, and find it rather more tender than Tom Thumb or Trentham Scarlet. It is a fine plant for an edging to beds, and has an excellent effect in chain and ribbon-borders. We think that in your case something very obnoxious to the roots is present in the soil in rather large quantity, or the leaves would not wither and die off as you represent. This Geranium likes a rather dry light soil, but in other respects its treatment does not differ from that of bedding Geraniums generally, except in its requiring to be taken up and potted a fortnight earlier in autumn, for cold rains make sad havoc among the foliage; and it ought not to be planted out so soon in summer by ten days or a fortnight.

MAKING A FRUIT GARDEN—PROTECTING FRUIT TREES (H. C.).—We agree with your plan so far as regards planting the wall 100 feet long and 10 feet high with Peach and Nectarine trees, and we know of no reason why you should not plant some part of the space with the other fruits named; but we do not approve of your plan of having a fixed frame of iron wire netting to protect them from birds. Recently we had an inquiry whether these contrivances would answer for protecting the blossoms of fruit trees from frost in spring and the fruit from the attacks of birds. We are glad to have an opportunity of disabusing our readers of such an idea, and to observe that the birds and fruit of the Peach and Nectarine are rarely if ever, preyed upon by the feathered tribe; that wire netting affords no protection to the bloom from spring frosts; that birds do not devour the buds of Strawberries and Raspberries, and consequently the netting is of no use for them at any period except when the fruit is ripening; that from the time of the fruit being ripe to that of the leaves falling birds do not prey on the buds of Cherry trees, Currants, and Gooseberries—the wire netting is consequently of no value at that time, but obstructs much of the sun's light and heat, so necessary to the perfecting of the wood and maturing of the fruit-buds, on which depend next year's prospects; lastly, that half-inch wire netting fixed over fruit trees will obstruct one-sixth of the sun's light and heat, and whilst it will not prevent the attacks of insects it will effectively shut out their natural enemies the birds. Had we such a space of 32 feet in width and so good a wall, we would in the first place examine the soil, and if it was drained of superfluous water, and of a moderately stiff nature, we would merely trench the ground two spits deep. If not drained we would run one drain up the middle of the space at a depth of 4 feet; and if sandy, light, and poor we would add some stiff loam, give a good dressing of cow-dung, and through trenching it we would tread it firm. We would then plant Peach and Nectarine trees 20 feet apart, the first tree 10 feet from one end, and the remainder 20 feet apart, so that five trees would be necessary. These may be 1 Royal George, 1 Grosse Mignonne, 1 Noblesse, and 1 Early York Peach, and 1 Elrige or 1 Violette Hâtive Nectarine. The produce when the trees were in full bearing would be about 1000 Peaches and Nectarines. The most suitable material to protect the bloom from frost is woollen netting with quarter-inch meshes. This may be purchased at about 8d. per yard; but if you do not mind the expense, the best thing that could be done would be to cover the wall with glass. Having a good back wall, you would only need upright posts in front, which should be left 4 feet out of the ground, and be covered with three-quarter-inch deals, the uppermost but one being hung on hinges for ventilation. The sashes would be 20 inches apart—that is, the rafters, for we would dispense with the sash system altogether, leaving a space at top 2 feet wide, which would be fitted with a glazed frame to open the full length of the house by lifting up. Glazed and fitted up in every way as a lean-to house 15 feet wide, 10 feet high at back, and 4 feet in front, an admirable fruit-house might be constructed. Peaches and Nectarines might occupy the back wall, 6 feet from which you might have a row of Peaches and Nectarines in pots, or planted out 4 feet apart, and trained as pyramids; 3 feet from these towards the front there might be a row of Plums as bushes, and 3 feet from these again a row of Cherries, planted in quincunx fashion. A house of this kind would be far preferable to a wire cage. With but ordinary management it would afford some very fine fruit, whilst if well managed it would be profitable as well as afford a delightful occupation. If you do not approve of this, which would not cost much more than a useless wire cage, we would plant the Peach trees as before stated, and 4 feet from the wall mark out a bed 4 feet wide, and plant it with Eclipse Strawberries. We would then leave a two-feet alley, and have another bed 4 feet wide, and in this plant La Constante and Keens' Seedling Strawberries; then another four-feet bed with a two-feet alley between it and its neighbour, and in this plant a row of pyramidal Cherries 6 feet apart, and two rows of British Queen Strawberries. 3 Feet from the edge of this bed we would plant a row of Fastol Raspberries 3 feet apart, and 4 feet from it a row of Black Currants and Red Currants, which would leave space in front for one row of Gooseberries ultimately, but two to begin with. Now, for protecting the Strawberries nothing surpasses ordinary netting, such as herring-nets, which may be purchased for a mere trifle per yard; but for the Cherries, Raspberries, Currants, and Gooseberries wire netting is better. We advise you to employ nets of any kind but sparingly, and never except when absolutely necessary, and then they should be made moveable; and it is for you to decide whether flexible netting would not be much more handy and also more economical than wire netting. In conclusion we would say, presuming you to have the house, you would plant a row of Raspberries in the ground in front of the house, 4 feet from it; at a like distance from these a row of Black and Red Currants; 3 feet farther off a row of Gooseberries; and in front of all, three rows of Strawberries, the first 3 feet from the Gooseberries, and the other 4 feet from the first. We have no doubt but that either of these arrangements would afford you a quantity of ripe fruit.

PINK LOBELIA (*E. L. W.*).—Kermesina Lobelia is as dwarf and compact as speciosa, but when raised from seed, the seedlings vary in habit and shade. We have pretty well decided on not using it freely for one reason—there is no means of keeping birds from it when young, unless stringing it or netting it over. As soon as the pink flowers showed away went flower and plant too, unless firmly fastened. When the plants are fully established the birds do not touch them. They served us with this Lobelia exactly as they did with young seedlings of Beet.

AQUATICS IN POTS (Rugby).—You may grow some in pots or pans without holes in them, or these closed up, if you place a few inches of stiff loam at the bottom. We have grown many kinds in pans, 1 foot 6 inches wide and 1 foot deep, without any holes of course at the bottom, this and the outside being glazed. At the bottom we placed from 4 to 6 inches of stiff loam two-thirds, and spongy boggy peat one-third, and in this compost we put in the plants, one or more in each according to the size, making them secure with a few stones upon the roots, or fastening them with pegs. Sufficient water was then added to allow of the leaves floating, or just covering them if of erect habit, adding more water as growth advanced until the pan was full to the brim. Aquatics require a light and airy situation, and the temperature necessary for the species. Rain water is the most suitable for them, though hard water will do if exposed to the atmosphere some time prior to using it. You name Pontederas, of which Pontederia cordata and *P. angustifolia* are all but if not quite hardy, but they do well in a greenhouse temperature; *P. azurea*, from Jamaica, requires a warm greenhouse; and *P. lanceolata* a temperature of at least 45° in winter to do well; *P. crassipes*, from Guiana, requires the heat of a warm stove; and *P. dilatata* the ordinary heat of a stove; *Thalia dealbata*, from South Carolina, does well in a warm greenhouse. In addition to these you may have *Richardia ethiopica maculata*, a fine-leaved kind, and the species; *Peltandra virginiana*, the majestic *Papyrus elegans*, the Two-spined Water Caltrops (*Trapa bispinosa*), which is a biennial; the Two-horned (*T. bicornis*), a perennial from China; *Sagittaria graminea*, *S. Doniana*, and *S. lancifolia*.

INSECTS, DESTROYING (Y. G. C.).—Syringing the foliage of the Dianthus with tobacco water made by pouring a gallon of boiling water on an ounce of shag tobacco will free them of the aphis, but it may be necessary to repeat the dose. Water freely at the roots with weak liquid manure, which may be made by dissolving 2 ozs. of guano in a gallon of rain water, and this with frequent sprinklings of water overhead should enable your plants to outgrow the enemy. As the seeds of the Kaulfussia did not come up they must have been bad or sown too deeply. Insects had nothing to do with destroying them. Give the ground a dressing of quicklime in the spring, or in the autumn if the ground be then dug, and another dressing of soot in the spring, which should be mixed with the soil or forked-in, and this will improve the soil and render it distasteful to worms and grubs.

FLOWER-GARDEN PLAN (J. W. Boyd).—We have no fault whatever to find with the proposed plan of the flower garden in front of the range of houses. Such a plan would look best with slate, stone, or Box edgings, and gravel between. There scarcely seems room enough for grass between the beds. Well planted, the pair of similar groups, of five clumps each, would look well. We cannot say so much for the proposed arrangement on the south and lower level of lawn. Why should the Wellingtonia be placed in the centre of the diamond in the middle? and what beauty can there be in the four acute-angled triangles round it? As the Pinus tribe flourish so well with you, suppose that you place the Wellingtonia on the open lawn, and two Araucarias and two Deodars in the four corners, so as to give them room to grow, and then have a couple of ovals or circles for the Sikkim Rhododendrons. The roundness of their outline will contrast favourably with the acute angles on the upper terrace, but which there are quite at home. Were the inner platform made into a flower garden, we would have a different style from that adopted on the upper platform. We are pleased to hear of the health of the Vines, Araucarias, Rhododendrons, &c. The only explanation which we can offer as to your not finding flower-garden plans at the pages you mention, is that you must have taken up the wrong volume. The references are quite correct as applied to Vol. VI., to which they belong.

WALL TREES INFESTED WITH INSECTS (S. T.).—Any time after the leaves have fallen up to the middle of February undo the trees from the wall, and if the mortar be much perished point up the nail-holes; and when this is done paint the wall from top to bottom with half a peck of lime, an equal quantity of soot, and 2 lbs. of sulphur vivum, made into the consistency of thick paint by a sufficiency of urine heated to boiling point. This solution well rubbed into every hole and crevice of the wall will be a dish that few insects like. In addition to this the trees should be dressed with a solution of sulphur vivum 2 lbs., soft soap 2 lbs., and 1 lb. of the strongest shag tobacco. Boil the tobacco in water for an hour and let it stand until cool, then strain, and dissolve the soft soap in it, and add the sulphur and sufficient hot water to make it five gallons at a temperature of 180°. With this paint every shoot and stem, rubbing it well into every hole and crevice of the bark and joints of the wood, being careful not to dislodge the fruit-buds. The wash should be applied with a brush, and in winter before the buds begin to swell. An effectual mode of exterminating ants is to mix arsenic with sugar and water to the consistency of treacle, or equal quantities of honey and arsenic, either of which the ants greedily devour; but care must be taken that no animal have access to it. Guano will drive them away, and lime water will dislodge them. See remarks on this subject in Nos. 178 and 179.

NAMES OF PLANTS (A. M.).—Your "Thistle" is not a Thistle, but *Tragopogon pratensis*, or yellow Goat's-beard. The other plant is *Helianthemum vulgare*, common Rock-rose or Dwarf Cistus. (*Alpha, Acton*).—1, *Polygonum vulgare cambricum*; 2, *Lastrea dilatata*. (*E. F.*).—1, *Spiranthes autumnalis*; 2, *Asplenium trichomanes*; 3, *Doodia caudata*; 4, *Onychium surratum*; 5, *Doodia media*. (*M. D., Richmond*).—Your plant is not a true Bignonia, but belongs to the allied genus *Pithecoctonium*. As far as we can make out it is an undescribed species, but we will endeavour to ascertain more about it. The flowering of the Ailanthus is not an uncommon event.

judges fully bears that out. The Club, we know, has many enemies, but I am pleased to say treble the number of friends; and, as a member of it, I fearlessly assert its sole object is "a fair field, and that the best birds may win." Its rules, with which so much fault is found, I admit are not faultless; but, then, my principle is not to cry the whole thing down, but join, and then remedy the fault. Poultry shows are surely few enough (at least, of this stamp), and keep getting less, so that, instead of opposing, it should be the earnest desire of all exhibitors to work together to establish such Shows as these on a sound and firm basis. I fearlessly maintain a more suitable building, or a better manager than Mr. Douglas (if his equal), cannot be found.

As regards the appointment of Judges, I, for one—and I never heard but the one opinion—consider it far better the Judges' names should not be published, or that even they should be selected so long in advance. Three gentlemen will be at Islington of well-acknowledged repute, and who have the confidence of exhibitors in general. They were once large and most successful breeders, though now retiring from the arena as exhibitors.

"AN EXHIBITOR" seems hard put to, to find fault when he wants to know who guarantees the payment of the prizes. Have the former Shows broken faith with their supporters? I challenge "AN EXHIBITOR" to prove anything at all against them; and I doubt not, if there be many of his class, which I do not for one moment suspect there are, the whole of the money would be lodged in some bank, or the Editors' hands.

In conclusion, I would fain urge exhibitors to pull together and support such Shows, and not condemn anything without a trial. I trust to see such a gathering that has never before been witnessed in the metropolis.—A STEWARD.

DEWSBURY POULTRY AND PIGEON EXHIBITION.

YEAR by year this Show has risen in public estimation, and without a doubt the meeting just held has been the most successful of any. This is a matter of congratulation, but at the same time it is the just reward of the efforts made by the directing Committee; and with care it is probable that the Dewsbury future shows will stand high in the ranks of our poultry exhibitions.

There is one little comment to be made on the arrangements. The pens might be improved; and as the wirework is fast becoming imperfect, we would suggest in future shows either to renew it altogether, or to provide new wire folding-pens. These would soon give a return of the first outlay if lent out to neighbouring shows on hire, or even, in fact, by the advantages they would afford to the Dewsbury Show alone, if laid by from year to year. August 31st, the day of the Show, was one of those eccentric vicissitudes of weather for which our fatherland is so proverbial. At the earliest dawn everything promised most favourably. About six o'clock A.M. a scudding shower caused a little anxiety, but it was so transient that all fears were soon banished by a temporary sunshine. At eight, however, the most gloomy apprehensions were hopelessly indulged in by the reputedly weatherwise. It rained for an hour incessantly, and so violently that the workmen employed could not possibly go on, and every one deplored the now apparent certainty of complete failure. Every object as far as the eye could reach was completely drenched, and as an aged agriculturist observed in our hearing, "this is a glorious rain for our turnips and pasture lands, but it's certainly settled the Show." We, as did all others, rejoiced to find his prophecy unfulfilled, for between nine and ten a good sharp breeze arose, the sun shone with redoubled power, the roads and grass were soon equally dry, matters progressed rapidly, and though the Show was a little delayed, the event proved that, nothing daunted, one continuous throng of visitors filled the grounds from midday to nightfall.

As to the quality of the Poultry and Pigeons all were exceedingly good, but the old birds did not show to the advantage they will do when they have attained full feather. We purpose, therefore, confining our remarks to a few only of the principal pens that had somewhat renewed their plumage. In Cockins Miss Beldon exhibited some first-rate

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE AGRICULTURAL HALL SHOW AND THE POULTRY CLUB.

I DID not intend to enter into the above controversy, but the letter of "AN EXHIBITOR" demands some notice, so I trust you will allow me a short space in your columns.

What the motive can be for attacking the Show I cannot conceive. I believe the Show to be got up on the most impartial principle, and the fact of asking the Club to select

Buffs both old and young; and the same was equally the case with the White Cochins shown by Mr. Dawson, of Hopton, Mirfield. Among the many excellent chickens shown we must briefly allude to both the Golden and Silver-spangled *Hamburgs* of Miss Beldon, for they are such as augur many triumphs yet to come. Mr. Dyson's Black Red Game chickens (pen 60), were equally praiseworthy—in fact, as good as any yet shown this year, and very early ones. The Game sweeps for single cocks were as nearly a failure as could well be imagined, two of the so-called "sweepstakes" containing only a single entry, and the third having but two birds in competition. The great uncertainty of getting up a competition by the sweepstakes arrangements brings them day by day into greater public disfavour. If not more freely supported, as a matter of course, Committees of poultry shows have no alternative save to abandon them altogether; for to call a bird a "winner" when there are none to dispute his title, and again to win only his own entry fee back, deducting expenses (as enforced by the schedules issued for these classes), is ill-calculated to increase the popularity of such "sweepstakes." Before concluding our remarks on the poultry we cannot forbear a brief allusion to the class in which a "Committee's silver cup" was given for the best pen of poultry (any breed) in the Exhibition, but to be specially entered at increased fees for this class, though still enjoying the privilege of competing in their respective classes also; or exhibitors could enter singly for this cup only. A very spirited and capital competition of twelve first-rate pens ensued, embracing many of the principal prize-winners in the previous arbitrations. Mr. Cannan, of Bradford, was the winner with a beautiful pen of *Spanish* chickens, but very closely pressed by nearly the whole of the twelve competitors. As a single cup was only to be awarded, and these prize birds had still to take their places in their original positions after the cup was awarded, no high commendation was recorded in this special class, as it would have only led to many misapprehensions if found attached to pens already boasting a first or second prize in their own variety, otherwise every one was well deserving of this especial recognition of good quality.

The Pigeons were good, but the very heavy gale of wind was much against them; the Carriers evidently becoming almost blinded by its effects. This variety of Pigeon, when confined within its power, suffers seriously from continuous wind; so much so as sometimes to be permanently injured.

COCHIN-CHINA.—First, Miss E. Beldon, Bingley. Second, W. Dawson, Hopton. *Chickens.*—First, Miss E. Beldon. Second, W. Dawson. Highly Commended, R. Wade, Halifax.

SPANISH.—First, Miss E. Beldon. Second, W. Cannan, Bradford. Highly Commended, R. J. Wood, Manchester. *Chickens.*—First, W. Cannan. Second, J. Vickerman, Chickenley. Commended, E. Brown, Sheffield.

DORKING.—First, Miss E. Beldon. Second, E. Leach, Rochdale. *Chickens.*—Prize, E. Leach.

HAMBURG (Golden-spangled).—First, Miss E. Beldon. Second, W. Cannan, Bradford. *Chickens.*—First, Miss E. Beldon. Second, H. Carter, Holmfirth.

HAMBURG (Silver-spangled).—First, Miss E. Beldon, Bingley. Second, W. Cannan, Bradford. *Chickens.*—First, W. Cannan. Second, Miss E. Beldon.

HAMBURG (Golden-pencilled).—First, J. Sunderland, Coley, Halifax. Second, Miss E. Beldon. *Chickens.*—Prize, Miss E. Beldon.

HAMBURG (Silver-pencilled).—First, Miss E. Beldon. Second, W. Cannan. *Chickens.*—Prize, Miss E. Beldon.

POLAND (Gold or Silver-spangled).—First and Second, Miss E. Beldon. *Chickens.*—First and Second, W. Newsome, Bingley.

POLAND (Any other variety).—First, W. Newsome. Second, Miss E. Beldon. *Chickens.*—Prize, W. Newsome.

GAME (Black-breasted and other Reds).—First, E. Beldon, Bingley. Second, H. Snowden, Bradford. *Chickens.*—First, T. Dyson, Halifax. Second, J. Fell, Adwalton. Highly Commended, J. D. Newsome, Batley; J. Mason, Staincliffe; J. Vickerman, Chickenley. Commended, J. Sunderland, Coley, Halifax.

GAME (Duckwings and other Greys and Blues).—First, Miss E. Beldon, Bingley. Second, J. Fell. *Chickens.*—First, J. Fell. Second, H. Snowden. Commended, T. Vickerman.

GAME (White and Piles).—First, J. Sunderland. Second, H. C. Mason, Drighlington. *Chickens.*—Prize, W. Whiteley, Liversedge.

GAME (Black and Brassy-winged, except Greys).—First, Miss E. Beldon, Bingley. Second, J. Oldroyd, Dewsbury Moor. *Chickens.*—First and Second, J. D. Newsome, Batley.

BANTAMS (Gold and Silver-laced).—First, W. Cannan, Bradford. Second, Miss E. Beldon.

BANTAMS (Black and Silver-laced).—First, C. A. Ridgway. Second, W. Cannan.

BANTAMS (White and Silver-laced).—First and Second, S. Schofield, Heckmondwike.

BANTAMS (Game).—First, C. Lister, Mirfield. Second, W. T. Entwistle.

ANY BREED NOT MENTIONED.—First, J. D. Newsome, Batley. Second, C. Lister, Mirfield. Highly Commended, Miss E. Beldon, Bingley; W. K. Duxbury, Leeds. Commended, E. Leach, Roohdale. *Chickens.*—First, H. Lacy, Hebden Bridge. Second, Miss E. Beldon, Bingley.

DUCKS (White).—First, E. Leach, Rochdale. Second, Miss E. Beldon, Bingley.

DUCKS (Rouen).—First, E. Leach, Rochdale. Second, J. D. Newsome, Batley.

GESE.—First and Second, W. K. Duxbury, Leeds.

SWEEPSTAKE COCK (Any Colour).—Prize, H. G. Mason, Drighlington.

SWEEPSTAKE GAME COCKEREL.—First, H. C. Mason. Second, T. Vickerman, Chickenley.

SWEEPSTAKE GAME BANTAM COCK (Any Colour).—Prize, Wallis & Oldroyd, Dewsby.

PIGEONS.

POWTER.—*Cock.*—First, H. Brown, Sheffield. Second, Miss E. Beldon, Bingley. *Hen.*—First, H. Snowden. Second, Miss E. Beldon.

CARRIERS.—*Cock.*—First, J. Firth, jun., Dewsbury. Second, J. W. Edge, Birmingham. *Hen.*—First, J. Firth, jun. Second, Miss E. Beldon, Bingley.

TUMBLERS (Almond).—Prize, H. Snowden.

TUMBLERS (Any other variety).—First, H. Snowden, Bradford. Second, H. Yardley, Birmingham. Highly Commended, Miss E. Beldon, Bingley.

TRIBITS.—First, H. Yardley. Second, Miss E. Beldon. Commended, H. Brown, Sheffield.

JACOBINS.—First, Miss E. Beldon, Bingley. Second, H. Yardley, Birmingham.

TRUMPETERS.—First, Miss E. Beldon. Second, F. Key, Beverley.

OWLS.—First, J. W. Edge. Second, Miss E. Beldon. Highly Commended, H. Brown, Sheffield.

BARS.—First, J. Firth, jun., Dewsbury. Second, Miss E. Beldon, Bingley. Commended, J. Firth, jun.; H. Yardley, Birmingham.

FANTAILS.—First, J. Firth, jun., Dewsbury. Second, J. W. Edge, Birmingham.

NUNS.—Prize, J. W. Edge, Birmingham.

CORONAS.—First and Second, J. Vickerman, Chickenley. Commended, Wallis & Oldroyd, Dewsby.

ANY OTHER VARIETY.—First, H. Yardley, Birmingham. Second, Miss E. Beldon.

RABBITS.—*Lop-eared.*—First, W. H. Firth. Second, J. W. Nutter, Dewsby. *For Colour.*—First, C. A. Ridgway. Second, J. Squires, Rothwell.

For Weight.—Prize, T. Smith, Dewsbury Moor.

SILVER CUT FOR BEST PEN IN THE EXHIBITION.—W. Cannan (Spanish Chickens).

JUDGES.—Mr. Thompson, of Saint Ann's, near Halifax; and Mr. Hewitt, of Sparkbrook, near Birmingham.

HALIFAX AND CALDER VALE POULTRY SHOW.

THE twenty-sixth annual Exhibition took place on Saturday the 27th ultimo, in Clare Hall Park, Halifax, which had been kindly lent for the occasion by Joshua Appleyard, Esq. The day was beautifully fine, and the attendance of visitors very great, the Park being densely crowded in every part. The arrangements were admirable in every respect. Poultry numbered 383, and Pigeons 137 pens.

Spanish were good classes, Messrs. Cannan, Rodbard, and Beldon each exhibiting specimens of great merit. The first-prize chickens, we thought, should scarcely have been so high in the list, for, although good, the second-prize pen contained a superior cockerel and a good pullet.

Dorkings did not show to advantage; the prize pens were of average quality in adults, while the chickens contained some good birds.

In *Cochins* Miss Beldon, Captain Heaton, and Mr. Stretch took the prizes for Buffs with capital pens—indeed, seldom have such really good birds competed at an agricultural show. In Any other variety of *Cochins* first prizes were awarded to Partridge, Whites taking second.

Brahmas numbered twenty pens, ten in each class, and Mr. Lacy outdistanced competition in both classes with splendid dark-coloured pens.

For the best *Game Cock* or *Cockerel* Mr. Fletcher had the silver cup, value five guineas, with a magnificent Brown Red cock well shown, Black Reds taking second and third, a splendid Brown Red and a Duckwing receiving high commendation. The first-prize single *Game cockerel* shown by Mr. Dyson, a Black Red, deserved his position, though we fancied him too much cramped in foot. In Black Red Game Mr. Brierley's first-prize pen in old birds was good; and Mr. Crosland's first-prize chickens were very promising, while the second contained a bad-footed cockerel. In Brown Reds Mr. Aykroyd took first with a capital pen, the hen being unusually good. The chickens of the same colour were a wretched lot. The cockerel in the first-prize pen was duck-clawed, and poor in every respect. Old Duckwings were in force though much out of feather, the first and second pens being most noticeable. In chickens of the same colour Mr. Aykroyd's first-prize pen was splendid—the pullet of unusual

excellence, the cockerel capital in colour and shape, though requiring more development—a better pen we have seldom seen. In Any other Game, good Blacks were first in the old class.

In Polands White-crested Blacks, shown naturally, were first, Silver second. In chickens Silvers were first; the other two prizes being awarded to White-crested Blacks, the third-prize pen being excellent, and should have taken a higher grade.

Hamburgs were numerous and good, this district being noted for these varieties, the Golden-spangled and Silver-spangled deserving especial mention. Miss Beldon had a large proportion of the prizes with pens wonderful in condition, and of great merit.

Any other distinct breed brought out Mr. Dawson's beautiful Sultans in old birds. In chickens Andalusian took first.

The prize Game Bantams were capital; and the Laced and Other variety class contained many good pens.

Mrs. Seamons added another triumph to her list in Aylesbury Ducks. The Rouen were, however, superior in quality, the first and second pens more especially.

Geese and Turkeys were an average lot.

The following is the prize list:—

SPANISH.—First, W. Cannan, Bradford. Second, J. R. Rodbard, Wrington, Bristol. Third, Miss E. Beldon, Bingley. *Chickens.*—First, J. R. Rodbard. Second, W. Cannan. Third, Miss E. Beldon.

DORKING.—First, W. Gaman, Thornton-le-Moors. Second, Miss E. Beldon, Bingley. Third, C. W. Brierley, Middleton. *Chickens.*—First, C. W. Brierley. Second and Third, Rev. J. F. Newton, Kirby-in-Cleveland. Highly Commended, Miss E. Beldon.

COCHIN-CHINA (Cinnamon or Buff).—First, Miss E. Beldon. Second, E. Smith, Middleton. Third, T. Stretch, Ormskirk. *Chickens.*—First, Capt. Heaton, Manchester. Second, T. Stretch. Third, Miss E. Beldon. Highly Commended, C. E. Ridsdale, Skircoat; C. T. Bishop, Lenton, Nottingham.

COCHIN-CHINA (Any other variety).—First, T. Stretch (Partridge). Second, W. Dawson, Mirfield (White). Third, W. Bowley, Cirencester. *Chickens.*—First, T. Stretch (Partridge). Second, W. Dawson (White). Third, R. Wade, Halifax.

BRAHMA POOTRA.—First and Second, H. Lacy, Hebden Bridge. Third, Mrs. Seamons, Aylesbury. *Chickens.*—First, Second, and Highly Commended, H. Lacy. Third, T. Pomfret, Preston. Highly Commended, Mrs. Seamons.

GAME COCK OR COCKEREL (Any colour).—Cup, J. Fletcher, Manchester. Second, W. Boyes, Beverley. Third, T. Bottomley, Shelf. Highly Commended, Miss E. Beldon; H. Adams, Beverley.

GAME COCKEREL (Any colour).—First, T. Dyson, Halifax. Second, H. C. Mason, Leeds. Third, G. Noble, Dewsbyr.

GAME (Black-breasted Reds).—First, C. W. Brierley, Middleton. Second, J. Sunderland, jun., Coley Hall. Third, J. Firth, Ellen's Grove. *Chickens.*—First, J. Crossland, jun., Wakefield. Second and Third, T. Dyson, Halifax. Commended, J. Firth.

GAME (Brown-breasted and other Reds).—First, E. Aykroyd, Bradford. Second, W. Gaman, Thornton-le-Moors. Third, Miss E. Beldon. *Chickens.*—First, J. Firth. Second, J. Crossland, jun. Third, R. Hemingway, Shelf.

GAME (Duckwing, Grey, and Blue).—First, D. Crossley, Haley Hill. Second, E. Aykroyd, Bradford. Third, W. Bentley, Cleckheaton. Highly Commended, C. W. Brierley, Middleton. *Chickens.*—First, E. Aykroyd. Second, H. Snowdon, Horton. Third, G. Hartley, Leeds.

GAME (Any other variety).—First, Miss E. Beldon. Second, J. Hanson, Hipperholme. Third, Master D. Edwards, Fixby Park. *Chickens.*—First not awarded. Second, G. Noble, Dewsbyr. Third, B. Taylor, Heckmondwike.

POLAND.—First, H. Carter, Holmfirth. Second and Highly Commended, Miss E. Beldon. Third, J. Smith, Keighley. *Chickens.*—First, Miss E. Beldon. Second, H. Carter. Third, J. Smith.

HAMBURG (Golden-pencilled).—First, R. Hemingway, Shelf. Second, S. Smith, Northowram. Third, J. Hollings, Horton Bank Top. *Chickens.*—First, S. Smith. Second, R. Hemingway. Third, Miss E. Beldon.

HAMBURG (Silver-pencilled).—First and Second, Miss E. Beldon. Third, J. Sunderland, jun. *Chickens.*—First and Third, W. Maude, Bingley. Second, Miss E. Beldon. Highly Commended, J. Stell, Keighley.

HAMBURG (Golden-spangled).—First, Miss E. Beldon. Second, W. Cannan, Bradford. Third, Mrs. H. Sharp. Highly Commended, C. Cowburn, Leeds.

HAMBURGS (Any other variety).—First and Second, Miss E. Beldon. Third, C. Pease, Darlington. *Chickens.*—First, J. Hargreaves, Skipton. Second, Miss E. Beldon. Third, S. Briggs, Holywell Green.

ANY OTHER DISTINCT BREED EXCEPT BANTAMS.—First, W. Dawson, Mirfield (The Sultan's Fowls). Second, C. W. Brierley. Third, C. Lister, Mirfield (Silkie). *Chickens.*—First, W. Barber, Ovenden (Andalusian). Second, M. Smith, Ainalies (Malays). Third, C. Lister (Silkie).

BANTAMS (Game).—First, G. Noble, Staincliffe, Dewsbyr. Second, J. Crosland, jun., Wakefield. Third, R. M. Stark, 6, Claremont Terrace, Hull.

BANTAMS (Gold or Silver-laced Sebright).—First and Third, Miss E. Beldon. Second, W. Cannan.

BANTAMS (Any other variety).—First, W. Cannan. Second, G. Noble. Third, S. Schofield, Heckmondwike.

DUCKS (Aylesbury).—First and Second, Mrs. Seamons, Hartwell, Aylesbury. Third, F. M. Hindle, Bury New Road, Haslingden.

DUCKS (Rouen).—First and Second, S. Briggs. Third, G. Noble.

DUCKS (Any other variety).—First, S. Briggs (Wild). Second, J. Oates, Pelton. Third, J. R. Jessop, Beverley Road, Hull Wild.

GEESSE.—First, W. K. Duxbury, 9, Primrose Road, Leeds. Second and Third, H. Edwards, M.P., Pye Nest (Canadian Geese).

TURKEYS.—First, C. W. Brierley. Second, Hon. Lady Hawke, Womersley Park, Pontefract. Third, W. Cannan.

SELLING CLASS (Any Breed).—First, Miss E. Beldon. Second, W. Smith, Beech Hill. Third, S. Briggs (Golden-pencilled Hamburgs).

PIGEONS.

In the Pigeon department the classes were well filled. Powters were good. In cocks a fine Blue was first; and in hens a lengthy White, rather short in leg, took a similar position. Mr. Eden's highly commended White cock should have had a step higher. In Carriers Mr. Eden had it all his own way, for, with the exception of a highly commended Black hen, there was nothing approaching the prize birds in either of the classes. The first Almonds, and first and second Black Mottled Tumblers were capital. Blue Beards and Black Balds had first and second in the class allotted to them. In Owls fine Whites took the prizes. In Turbits Silvers in beautiful condition were first; Reds, too coarse, were second; a good pair of Yellows were commended. Good Red Jacobins took first and second in the class for that variety. Fantails were not so good as we have seen. In Bars the first went to capital Blacks, the cock being defective in the colour of the eye, otherwise good in every other point, and accompanied by a fine hen—Yellows were second. Dragons were numerous, the first-prize pen of Blues was not equal to the highly commended pen of the same colour. Trumpeters were not so perfect as are generally shown at Halifax. The mottled cock in the first-prize pen was Mr. Shaw's famous old bird, accompanied by a poor hen. In Any other breed Blue Shields were first, and Satinettes second. In the selling class Black-headed Nuns were first, and Turbits second.

POWTERS AND CROPPERS.—**Cocks.**—First, S. Briggs. Second and Highly Commended, P. Eden, Cross Lane, Salford. Highly Commended, C. J. Samuels, Manchester. **Hens.**—First, H. Snowdon, Horton. Second, W. Smith. Highly Commended, E. Beldon, Gilstead, Bingley.

CARRIERS.—**Cocks.**—First and Second, P. Eden. Highly Commended, J. Firth, jun., Dewsbyr; B. Conderstone, Littlebrough. Commended, S. Briggs. **Hens.**—First and Second, P. Eden. Highly Commended, E. Beldon. **TUMBLERS (Almond).**—First and Second, P. Eden. Commended, H. Snowdon.

TUMBLERS (Mottled).—First and Second, P. Eden. Commended, S. Briggs.

BALDS OR BEARDS.—First, H. Yardley, Birmingham. Second, S. Briggs.

OWLS.—First and Second, P. Eden. Third, H. Yardley. Highly Commeded, J. W. Edge, Birmingham.

TURBITS.—First and Commended, S. Briggs. Second, J. Wade, Bradshaw Lane. Highly Commended, H. Yardley.

JACOBINS.—First and Second, S. Briggs.

FANTAILS.—First, S. Briggs. Second, H. Yardley.

BARBS.—First, W. B. Van Hansbergen, Newcastle-on-Tyne. Second and Highly Commended, P. Eden.

DRAGONS.—First, W. Smith. Second, S. Briggs. Highly Commended, S. Briggs.

WADSWORTH.—First, W. Smith; W. Gaukroger, Halifax; and C. J. Samuels.

TRUMPETERS.—First and Second, S. Briggs.

MAGPIES.—First, H. Yardley. Second, S. Briggs.

ANY OTHER BREED.—First, S. Briggs. Second and Commended H. Yardley. Highly Commended, P. Eden and C. E. Ridsdale, Skircoat.

SELLING CLASS.—First, H. Sunshall, Gedney. Second, W. Massey, Gedney.

JUDGES.—For **Poultry.**—Mr. Joseph Hindson, Liverpool; and Mr. Richard Teebay, of Fulwood, Preston. **Pigeons.**—Mr. H. Weir, London; and Mr. J. W. Thompson, Southwark, Halifax.

DEANE AGRICULTURAL SOCIETY'S POULTRY SHOW.

This Society held their first Show on Wednesday the 31st of August, in a field near the church. The rain fell very heavily in the early part of the day, but the weather afterwards cleared up, and was very fine, and the number of visitors was consequently large. The pens of poultry were not very numerous, but there were some very good birds.

The Spanish headed the list, but only one pen was sent. The Dorking were in very bad feather, dark birds being first, and Silver Grey second. The show of Game cocks was not very good; and in the class for cock and two hens, Brown Red took first, and Black Reds second. In the Cochin class there were only two pens, Buffs taking first, and Partridge second. In the Golden-pencilled there were some very good birds; the first-prize cockerel was beautiful. The Silver-pencilled were not so good. In Golden-spangled only three pens were entered; but in the Silver-spangled class there were some splendid birds, particularly the pullets in the first-prize pen. In Polands Blacks were first, and Silver

second. In the Any variety class only two pens were shown; the first-prize pen, belonging to Mr. Leach, of Rochdale, was very good. Of Game Bantams there was a large entry, but the quality was not very good. In Any variety of Bantams Silver-laced took the first prize, and Blacks second.

Of Aylesbury Ducks only two pens were shown. Mr. Leach had a very nice pen, their beaks being very good. There was a very large entry of Rouens, and it was a very good class; and in the Any variety class Carolina Ducks took first, and Call Ducks second. Three very nice pens of Geese were shown. The following are the awards:—

SPANISH.—Prize, S. Tyldesby, Farnworth.

DORKINGS.—First, S. Farrington, Astley. Second, F. Charlton.

GAME COCK.—First, J. Turner. Second, S. Farrington.

GAME COCK AND TWO HENS.—First, C. P. Ackers. Second, J. Turner, Radcliffe.

COCHIN-CHINA.—First, J. Wood, Brinscall Hall. Second, H. Wheeler, Middleton.

HAMBURGS (Golden-pencilled).—First, J. Haselden. Second, T. Wrigby, Middleton.

HAMBURGS (Silver-pencilled).—First, E. Crompton. Second, J. Platt, Deane.

HAMBURGS (Golden-spangled).—First, N. Marlor, Denton. Second, G. Whittaker.

HAMBURGS (Silver-spangled).—First, M. Isherwood, Redcliffe. Second, J. Fielding.

POLANDS.—First and Second, S. Farrington.

ANY VARIETY.—First, E. Leech (Brahma). Second, F. Bullock, Chowbent (Brahma).

GAME BANTAMS.—First, J. W. Morris, Rochdale. Second, J. Fletcher, Stoneclough.

ANY VARIETY BANTAMS.—First, S. Farrington. Second, J. Eckersby, Hyton.

DUCKS (Aylesbury).—First, E. Leech, Rochdale. Second, A. Bowden, Westhoughton.

DUCKS (Rouen).—First, J. Nelson. Second, T. Wakefield.

DUCKS (Any other variety).—First, J. Eckersby. Second, C. P. Ackers, Bickershaw.

GESE.—First, E. Leech. Second, L. Walls.

TURKEYS.—Second, E. Leech. First withheld.

EXTRA STOCK.—First, T. Bromlow, (Pigeons). Second, W. Markland, Deane.

The Judges were Mr. Richard Teebay, Preston; Mr. Elijah Smith, Middleton.

WIRRAL FARMERS' CLUB AUTUMN POULTRY AND PIGEON SHOW.

THIS Show was held in the Birkenhead Park on the 30th of August. The site selected was exceedingly well adapted for the purpose, being on the rising ground on the west side of the lower park. There was also a flower show, which added materially to the attractions of the general Exhibition.

DORKINGS.—First, Miss Davis. Second, W. Copple, Prescot.

SPANISH.—First, G. Garlick, Rock Ferry. Second, R. Davies, Chester.

GAME.—First, J. Foden, New Ferry. Second, J. Ferren, Birkenhead.

HAMBURGS.—Prize, G. Garlick.

ANY OTHER BREED.—Prize, F. Kelshaw, Great Crosby.

ANY BREED.—Prize, G. Garlick.

BANTAMS.—Prize, G. Maples, Wavertree.

COCHIN CHINAS.—First and Second, T. Stretch, Ormskirk.

DUCKS (Aylesbury).—Prize, W. Innman, Upton.

DUCKS (Rouen).—First, T. Stretch. Second, A. Woods, Sefton.

GESE (Grey).—Prize, Lady Cust, Leiston Castle.

GESE (White).—Prize, Miss F. H. Congreve, Burton.

TURKEYS.—First, Miss Davies. Second and Highly Commended, W. Davies, Lower Bebbington.

PIGEONS.—*Carriers.*—First and Second, W. Stalker, Liverpool. *Pouters.*

—First and Second, D. Thwaite, Rock Ferry. *Almonds.*—First, W. Stalker.

Second, H. Yardley, Birmingham. *Fantails.*—First, D. Thwaite. Second, H. Yardley. *Jacobins.*—First, T. D. Walker, Hoylake. Second, D. Thwaite. *Blue Rocks.*—First and Second, D. Thwaite.

The Judges for Poultry and Pigeons were Mr. Hindson, of Liverpool; and Mr. Woolley, of Bunbury near Tarporley.

DUDLEY HILL POULTRY SHOW.

THE second annual Show of the Dudley Hill Floral, Horticultural, and Poultry Society, was held at Dudley Hill, on Saturday the 27th of August. The day was fine and the visitors numerous; and there is every reason to believe that the usefulness of the Society is becoming apparent to all the inhabitants of the locality; and doubtless another year will witness an augmentation of the prize list.

There were twenty-one classes for poultry, and thirteen for Pigeons, but the latter were not well supported with entries, though in poultry there were a good number of pens comprising some very good birds. Mr. Cannan took a large

amount of the prize money, and showed well in most of the classes.

In Game Mr. Hodgson showed some very good pens; and in Game Bantams Mr. Tetley had a splendid pen of Furnace. We noticed some pens that had their legs very neatly done over with green colouring.

In Geese there was a beautiful pen of Spanish.

SPANISH.—Prize, W. Cannan, Bradford.

DORKINGS.—First, H. Firth. Second, W. Cannan.

GAME (Black-breasted and other Red).—First, J. Hodgson, Bradford.

Second, T. Sudwick, Dudley Hill.

GAME (Duckwings).—First, J. Hodgson. Second, T. Sudwick.

HAMBURGS (Golden-spangled).—First, J. Greenwood, Dudley Hill.

Second, W. Cannan. Highly Commended, J. Greenwood.

HAMBURGS (Silver-spangled).—Prize, W. Cannan.

HAMBURGS (Golden-pencilled).—First, J. Driver, Allerton. Second, W. Cannan. Highly Commended, J. Gomer.

HAMBURGS (Silver-pencilled).—First, W. Cannan. Second, J. Driver.

POLANDS.—First, W. Cannan. Second, T. Sudwick.

GAME BANTAMS.—First, E. Tetley. Second, H. Firth.

BANTAMS (Other variety).—First, W. Cannan. Second, J. Gomer.

COCK (Any variety).—First, W. Cannan. Second, J. Hodgson. Highly Commended, T. Sudwick.

GESE (English).—Prize, —Yates

GESE (Other varieties).—Prize, —Yates

DUCKS (Aylesbury).—First, W. Cannan. Second, —Yates

DUCKS (ROUEN).—First, W. Cannan. Second, —Dolby.

PIGEONS.—*Tumblers (Short).*—Prize, A. Field. (*Almond.*)—First, A. Field. Second, —Holmes. *Turbits.*—Prize, A. Field. *Antwerp.*—First, Second, and Highly Commended, A. Field. *Owls.*—First, A. Field. Second, —Waddington.

JUDGES.—Mr. E. Hutton, Pudsey; Mr. J. Beedon, Girlington; and Mr. J. Parkinson, Bradford.

PUDSEY POULTRY SHOW.

THE first Exhibition of Poultry and Pigeons, in connection with the Pudsey Floral Society, took place on Tuesday, August the 30th. The day was fortunately very fine, and the Show was well patronised, the press of visitors becoming so great in the evening that it was very difficult to obtain a fair view of the specimens exhibited.

The entries were very numerous, pens being shown by the best Yorkshire and Lancashire exhibitors, though some of the latter did not put in an appearance.

The class for Spanish contained a most excellent pen of chickens, which will doubtless stand high at many more shows. Cochins and Brahma Pootras were not as good as might have been expected. Most of the Game shown were in bad feather, but otherwise good. Of Golden-spangled Hamburgs there were pens not to be easily beaten; and the Silvers were also very good. Golden-pencilled Hamburgs were a good class, and an extra second prize was awarded for them. In Silver-pencilled Mr. Sharpe exhibited a pen containing a cockerel of rare quality; and the Black Hamburgs were both numerous and good. Of Game Bantams there were some excellent specimens; but the class for Black and White contained birds that, for the most part, were suffering from the moult. In Bantams the Any other variety class was the most interesting. The first prize went to a neat little pen of Cochins, the second to a perfect pen of Silver-laced, and the third to Silkkies. Polands were first-rate.

Aylesbury Ducks were very fine, but the variety class for Ducks was much better. The first prize went to a perfect pen of tame-bred Wild, and the second to East Indian.

In single cocks the first, second, and fourth prizes fell to Game, the third to Brahma Pootra, and the fifth to Spanish.

Of Pigeons there were fifty-one entries, comprising excellent specimens from the lofts of Messrs. Clarkson, Edge, Hughes, Yardley, Cowburn, Haansbergen, and Jessop. The birds were well fed and watered during the day, and all were despatched to their homes the same night.

The pens used on the occasion were Turner's, of Sheffield.

SPANISH (Black).—First and Second, W. Cannan, Bradford. Third, W. R. Duxbury, Leeds.

COCHIN AND BRAHMA POOTRA.—First, W. Cannan. Second and Third, C. Lister, Mirfield.

GAME (Black-breasted or other Reds).—First, J. Sunderland, Coley Hall, Halifax. Second, J. Hodgson. Third, F. Spencer, Pudsey.

GAME (Other varieties).—First, J. Hodgson. Second, J. Sunderland. Third, C. Lister.

HAMBURG (Gold-spangled).—First, W. Cannan. Second and Third, C. Cowburn, Leeds. Highly Commended, J. Greenwood.

HAMBURG (Silver-spangled).—First and Second, W. Cannan. Third, C. Cowburn.

HAMBURG (Gold-pencilled).—First, W. Cannan. Second, J. H. Sharpe, Bradford. Extra Second, W. Harker, Cottingley. Third, G. Wilson, Pudsey.

HAMBURGH (Silver-spangled).—First, W. Cannan. Second, W. Mand, Bingley. Third, J. H. Sharpe.

HAMBURGH (Black, White, Buff, or Cuckoo).—First, W. R. Duxbury. Second, W. Cannan. Third, W. Harker.

BANTAMS (Game).—First, C. Lister. Second, J. Newsome, Batley. Third, W. F. Entwistle, Otley.

BANTAMS (Black or White).—First, W. Cannan. Second and Third, C. Lister.

BANTAMS (Other varieties).—First, J. Newsome. Second, W. Cannan. Third, C. Lister.

POLAND.—First, W. Cannan. Second, D. Illingworth. Third, W. R. Duxbury.

DUCKS (Roman).—First, J. Harrison, Beeston. Second, W. R. Duxbury. Third, J. Newsome.

DUCKS (Aylesbury).—First, W. Cannan. Second, W. Jackson, Pudsey. Third, W. R. Duxbury.

DUCKS (Any other variety).—First and Second, J. R. Jessop, Hull (Wild and Black). Third, J. Oates, Halifax (Black).

SINGLE COCK.—First, H. C. Mason (Game). Second, J. Fell & Son (Game). Third, Lady Hawke (Brahma). Fourth, J. Sunderland (Game). Fifth, W. Cannan (Spanish).

PIGEONS.—Carriers.—First, J. Clarkson, Pudsey. Second, H. Yardley, Birmingham. Pouters.—First and Second, W. Hughes, Leeds. Dragons.—First, H. Yardley. Second, C. Cowburn. Owls.—First, J. W. Edge, Birmingham. Second, W. Hughes. Antwerp (Long).—First, J. W. Edge. Second, T. Ingram. (Short).—First, H. Yardley. Second, C. Cowburn. Turbits.—First, J. R. Jessop, Hull. Second, W. Hughes. Turbits (Long).—First, C. Cowburn. Second, W. Hughes. (Short).—First, W. Hughes. Second, H. Yardley. Fantails.—First, J. W. Edge. Second, W. Hughes. Other varieties.—First, J. W. Edge. Second, T. Sagan, Leeds.

Mr. Thos. Dodds, Ovenden, Halifax, officiated as Judge.

POCKLINGTON SHOW OF POULTRY, PIGEONS, AND CANARIES.

FOR many years past the town of Pocklington has enjoyed a reputation for one of the best local shows in the kingdom. No effort that can be made to promote its success is ever neglected by the Committee of management; and the townsmen of Pocklington show, also, every possible inclination to support it by all the means in their power; and this year it has in a pecuniary point of view been a most successful meeting. The weather, too, has been as fine as could be desired.

Game were first on the list, and almost every bird in the mould; Mr. H. Adams' Duckwings and Piles were about the best in the Show, but they appeared to be used up for this season. In Red Game the judgment did not meet the approval of certain parties, but at the Dewsbury Show next day, the first-prize Pocklington pen was again placed first by one of the best Judges in England (Mr. Hewitt). The first-prize Game chickens were very good, and it will be seen that they again took first at Dewsbury. They were Black-breasted Reds. The prize pens of Spanish were very good, and shown in splendid condition. Dorkings were a moderate class; both first-prize pens were worthy of their position. The show of Cochins was one of the best ever seen at a local exhibition, almost every pen in the classes was highly commended. The first pens were gems; the cock in the first-prize pen took the cup for the best pen in the Show. Mr. Beldon's Hamburgs took first prizes in all the classes, they were first-class birds and won with ease. There was a nice show of Bantams, and the prize birds would win at almost any show.

The Ducks and Geese shown by Mr. Young, of Driffield, were far ahead of all others in their classes.

Pigeons were very good, but not easy to judge, as they were in baskets not open at the sides, consequently it was difficult to form a just idea of what the birds were like. It would be a great improvement if the Committee would engage Mr. Turner's pens both for Poultry and Pigeons, as under the present system the fowls cannot be seen or judged to advantage.

The following is the prize list:—

GAME (Black-breasted and other Reds).—First, H. Beldon, Bingley. Second, H. M. Julian, Hull. Highly Commended, H. Adams, Beverley.

GAME (Duckwing and other Greys).—First and Second, H. Adams.

GAME (Any other variety).—First and Second, H. Adams. Chickens.—First, T. Dyson, Halifax. Second, Master J. Charlton, Manningham. Highly Commended, H. Adams; H. M. Julian.

SPANISH.—First, H. Beldon. Second, S. Robson, Brotherton. Chickens.—First, H. Beldon. Second, S. Robson.

DORKING.—First, M. Hunter. Second, W. Watson, Bishop Burton. Chickens.—First, M. Hunter. Second, W. Watson.

COCHIN-CHINA (Buff or Cinnamon).—First, Master J. Charlton. Second, C. T. Bishop, Lenton, near Nottingham. Highly Commended, T. H. Barker, Hovingham. Commended, R. Carling.

COCHIN-CHINA (Any other variety).—First and Second, J. Bell, Thirsk. Highly Commended, G. Hair, Bingley; R. White.

COCHIN-CHINA CHICKENS.—First, H. Beldon. Second, T. H. Barker. Highly Commended, Bown & Briggs, Harrogate; T. H. Barker.

HAMBURGS (Golden-spangled).—First, H. Beldon. Second, S. Camping, Cottingham.

HAMBURGS (Silver-spangled).—First, H. Beldon. Second, S. Camping. Chickens.—First, H. Beldon. Second, S. Camping.

HAMBURGS (Gold or Silver-pencilled).—First, H. Beldon. Second, O. A. Young. Chickens.—First, H. Beldon. Second, G. Pears.

POLISH.—First, H. Beldon. Second, O. A. Young.

BANTAMS (Game).—First, R. M. Stark, Hull. Second, G. Holmes. Highly Commended, W. Lawrence, Eaglescliffe.

BANTAMS (Gold or Silver-laced).—First, H. Beldon. Second, J. R. Jessop. Highly Commended, R. M. Stark.

BANTAMS (Any other variety).—First, R. M. Stark. Second, J. Gawan.

DUCKS (Aylesbury).—First and Second, O. A. Young.

DUCKS (Rouen).—First, R. J. Wood. Second, T. H. Barker. Comended, O. A. Young.

DUCKS (Any other variety).—First and Second, J. R. Jessop.

GEES.—First, O. A. Young. Second, J. Metcalf, Pocklington.

TURKEYS.—Prize, W. Dorser, Warter.

GUINEA FOWLS.—First and Second, O. A. Young.

PIGEONS.—Pouters or Croppers.—First, H. Beldon. Second, S. Robson.

Tumblers.—First, H. Beldon. Second, J. R. Jessop. Bars.—First, W. B. Van Haasbergen. Second, H. Beldon. Highly Commended, H. Yardley.

Jacobins.—First, H. Yardley. Second, S. Robson. Fantails.—First, J. R. Jessop. Second, T. Ellington. Highly Commended, T. Reynolds.

Trumpeters.—First, W. B. Van Haasbergen. Second, F. Key. Highly Commended, H. Yardley. Owls.—First, H. Beldon. Second, H. Yardley. Commeded, J. W. Edge. Turbits.—First, J. R. Jessop. Second, H. Beldon.

Carriers.—First, S. Robson. Second, W. B. Van Haasbergen. Any other variety.—First, S. Robson. Second, W. B. Van Haasbergen.

EXTRA STOCK.—First, Master Eldridge. Highly Commended, Major Hill.

JUDGES.—Mr. John Crossland, jun., Wakefield; and Mr. A Cattley, York.

PIGEONS AT THE DARLINGTON SHOW.

IN your last I see another letter from "A FANCIER" containing the information that Mr. Botcherby was the only Judge at Darlington, and charging me with jumping at conclusions. In reply to this I can only say, that I took the catalogue as my authority, thinking, naturally enough, that as it was printed and sent out by the authority of the Committee, its statements might be relied upon.

He also seems to think that I shall have some difficulty in verifying the statements made in my last respecting the cup bird. He does not say whether it is the age or the quality of the bird which he disputes. The age is not, I suppose, a matter of much consequence; but for all that, if required, I am quite in a position to prove my statement of his age to be correct; and with regard to the quality, the facts that he appears in the prize list wherever exhibited, and that he was bred by Mr. Eden, from the Dun cock with which he has taken first prize at Birmingham for the last two years, are, I think, sufficiently conclusive.—J. I. D.

RECOLLECTIONS OF AN OLD FANCIER—No. 3.

RABBITS.

IT is terribly hot even here on this hill. There is a dryness of the air and earth such as I never remember to have felt before. Ponds in the village are as dry as turnpike roads, springs are no longer running, well after well is failing, and an elastic springy lawn is a thing of the past. There is another evidence of the heat which is new to me, it is that the shadow of one of the finest Elms in England gives little alleviation to our misery. A tree is now too thin a shade, nothing but a block of building, (e.g., on the east side of a house of an afternoon) is thick enough to protect from the blazing, broiling heat.

It is just such weather as is described by Tennyson in his "Mariana in the South."

"With one black shadow at its feet,
The house through all the level shines;
Close-latticed to the brooding heat,
And silent in its dusty vines:
Nor bird would sing, nor lamb would bleat,
Nor any cloud would cross the vault,
But day increased from heat to heat."

If I read these lines on Christmas day I should feel hot. But if it is oppressive here on this hill, what must it be in Bath, that lovely yet hot city, built as it is, on the inside of a circlet of hills, teacup-shaped. I turn my telescope and bring the Bath hills near to me, and I almost fancy I hear the good citizens frying. My friends the working gardeners

tell me that last week labouring within high-walled gardens was something terrible to bear. What must this heat be in Fleet Street? even here it induces great idleness. Luther tells a tale of a lazy monk too idle to say his prayers, and who was accustomed to repeat the alphabet, and then add, "Take, O Lord, these letters and put them together even as thou wilt." Let us hope that he did this only in the dog days—I am fond of finding excuses for every one. Now, I feel inclined instead of writing, to repeat the letters, and ask the good genius that presides over "our Journal," to put them together as he will, but in vain,

"If you want a thing done you must do it yourself, John,"

says Longfellow.

Now, if I could imagine any one (well there might be some dear schoolboy fond of pets), who was kind enough to relish, and remember with pleasure two former papers by "WILTSHIRE RECTOR," entitled "Recollections of an Old Fancier," let such a kind individual be assured that there are other recollections to come on in due time, besides Nos. 1 and 2. There always lies before me, on my study desk, a slip of paper entitled "mems," and the first line of the memoranda is this—"unbaptised children." Now, a little slip of paper so entitled is in its turn filled up with various items, used, and torn up to give place to another, to be in its turn filled, used, and torn up. But each and every succeeding bit of paper is headed with "unbaptised children." For why? there are always some to be baptised. So of this "Recollections of an Old Fancier," there will always be some coming on.

I went into Rabbits at an early age, too early, for like many children's first pets, I fear my first pair of Rabbits were starved. N.B.—Little children if they have pets given to them, should also have a servant put in charge of them. The first Rabbits died; they came too soon to be appreciated, a boon unvalued because premature. But in due time, in the earliest of breeched days, pet fever set in. I will tell you how it came on, what induced it, and how the first symptoms showed themselves. Five-and-twenty years ago, books for boys, really sensible books—were very few, plenty of books of the moral tale kind, full of long words of Latin derivation, written in the true Johnsonian jack-boot style, unreadable and unintelligible to a boy. These were what one's maiden aunts gave one on birthdays, and very clean they remained all their days. Thorough-jolly books, for all boys are jolly, were rare indeed. There was dear old "Robinson Crusoe," to be sure; but Capt. Mayne Reid had not then written, neither had Mr. Atkinson brought out his "Boy Naturalists." I quote from memory, perhaps I am not quite right in regard to the title. Neither, again, did one's present-giving relatives and friends often come up to the tune of a five-shilling book. One cantankerous old gentleman, under an obligation to my father, did give me a five-shilling book once, but it was an apple of Sodom, for on opening the parcel it proved to be "Blair's Preceptor," and I wished it far enough, for he said in his note, that he expected me to read it (read a school book in play hours, indeed!), and that he would examine me in it. Well, the fates were propitious to me once when a boy, at any rate. Friends coming from a neighbouring city actually brought a copy of the then newly-issued "Boy's Own Book," price eight shillings and sixpence—think of it, eight shillings and sixpence! I got it only by a shave, for it was intended for my elder brother, but happily was considered too juvenile for him, so it was to be my book, and he was to read the "Scientific Recreations." It was mine, my very own. I have the precious volume now, and my own boys delight in it. Well, henceforth, from that lucky day, that glorious book was my library, my vade-mecum. It went out fishing with me on summer half-holidays; it cheered dreary November evenings. Oh! blessed little square book, to a boy well nigh inexhaustible. But the most delightful part to me was "The Fancier," it made me a fancier, and I am a fancier still.

Singing birds you have heard about; silkworms I cared not for after the first essay; but Rabbits, so comestable by every boy, and so great a source of delight, I did love. I began humbly, but improved in time. My spare hours were employed in making hutches out of old boxes, and I looked with pride upon my long row of them, fronted with iron

hooping (galvanised wire had not then been invented), with tin troughs made by my dear old tinker crony. My Rabbits paid, too, for being a day scholar at a grammar school I was able to supply the less fortunate boarders with my spare stock. Of course, their food came out of the governor's garden and corn bins. Great was my delight at every improvement. My stock rose thus—Ill-marked and common, then better marked, then Smuts, and Butterfly Smuts, then Half-lops, Oar-lops, and, triumph of triumphs, Full-lops. A certain doe, black and white, and perfect in dewlap, colouring, and shape, is well remembered by me, as I placed her for exhibition on a truss of hay with her little ones around her.

Nor let my grand buck "Sir Harry," be forgotten, an enormous fellow, yellow and white, and dark-nosed. How he drubbed the cat, threatened the dog, and almost beat life out of a Dorking cock. My Rabbits had reached perfection point, just as stage coaches had when railways came in, and having reached it, they gave way to a new fancy, that of Pigeons, but how that happened my next Number shall tell, which, it may be, will be less of a Number for schoolboys than this.—WILTSHIRE RECTOR, August, 19th.

RABBITS.

WHY is it that while so much pains are taken in the improvement of poultry and Pigeons, Rabbits are left almost unnoticed? Are not the Ostend Rabbits, or what are still better, the Patagonian Rabbits, worth a little care and trouble? A few hutches may be kept where there is no room for fowls, and the Rabbits are so healthy and pleasant to feed, that it is not only a delight to have them, but it saves many a butcher's bill.

A Patagonian Rabbit when only ten weeks old weighs from 8 lbs. to 9 lbs. They are ugly in appearance, having a large, broad head, and a single lop, but their usefulness quite makes up for their want of beauty; and if elegance and beauty are required, then have those lovely little creatures the Himalayas as well.

The large Rabbit consumes a great quantity of food, and I should like to know if such would thrive well fed only upon soaked grey peas and fine middlings mixed with white pea haulms, as when fed with oats they waste so much.—HENLEY.

[Rabbits have not been left unnoticed in our pages, and the contributions to them on the subject have been collected and published in a little volume, entitled "The Rabbit Book," which you can have free by post from our office for seven postage stamps. It contains full directions for feeding and managing, with portraits taken from live specimens of the principal varieties.]

WINTERING THE CUCKOO.

IN answer to a correspondent who asks information how to keep Cuckoos through the winter, I may state my experience, having kept one until November; I lost it then by its being choked. I fed mine on small pieces of liver, mutton, and wasps, but the bird seems to prefer the young grubs. I think if your correspondent can keep up a supply of grubs or beetles with the raw mutton and liver, he may manage to keep his bird through the winter.

On dissecting the gizzard of the Cuckoo, the old birds I find have in it a quantity of hairy caterpillars and beetles. A bird-preserved in this locality of no mean experience, has now a Cuckoo, and he tells me that he is confident that Cuckoos sleep for most of their time during the winter, and that this sleeping will not take place until the gizzard is quite full of caterpillars and beetles.

I have shot Cuckoos this season to dissect the gizzard, and I have found them to be as my friend says. He seems quite sanguine of success, and I shall watch his experience, and if he succeeds until November or December, I will communicate the result to THE JOURNAL OF HORTICULTURE.—R. D., Seaham.

TO KEEP HONEY.—M. Sands, Orange county, N.Y., directs to heat strained honey to the boiling point, and store it in

covered jars, where it will keep without candying. To prevent danger of burning, set the vessel in which it is to be heated into another containing water.

BEE-MANAGEMENT AND FOOD.

You or some of your numerous subscribers could, I feel sure, tell me the plainest, simplest, and cheapest method of managing a few stocks of bees. I have too great a dread of their stings to become a skilful apiarian: therefore the expensive and complicated hives I see generally used would not suit me. The working men I have in my garden know nothing of the proper way of handling bees beyond shaking down a swarm from a bough, and putting the hive on its stand afterwards; and it would take no small share of persuasion to induce me to enter the domains of my bees until at least twelve hours after that exasperating operation has been successfully concluded. In fact, I only endure bees for the sake of honey, which is almost a necessity in a remote country house like mine. I find the common straw hive does not suit my bee-house, besides having to sacrifice the insects when I want their stores.

I wish, also, to gain some information on the best flowers to plant for bee food. I have tried many, but found the bees seemed to like nothing so much as mignonette—not even white clover. Borage they do not much frequent, and few florists' flowers seem to please their taste. The heliotrope and Oxalis floribunda are exceptions. There is a little blue plant, of which I have a small bed, which they frequent. I send a bit of it, and will be obliged to you for its name. Some persons recommend me to sow patches of buckwheat near the house: is it a bee plant?

I once knew an old gardener who kept a large supply of bees, and was most successful in obtaining quantities of honey from them. He made three or four hogsheads of delicious metheglin (or mead) every year, besides all the combs he kept for the use of his employer's family. He fed his bees in winter on small birds, roasted well, and basted with honey or strong syrup of sugar and treacle. I have seen him take out the bare skeletons from his hives, therefore the bees must have eaten the meat off the bones. He used to say nothing agreed so well with bees as roasted birds. I shall wait with anxiety a reply through the columns of your Journal.—RUBY.

[With your dread of bees and the ignorance of your assistants, we cannot advise any attempt to advance upon the old and well-understood system of management. Destroy swarms as a rule, and you will insure young queens and obtain fine honey, but renew your old stocks by the substitution of swarms every five or seven years. If your bee-house is not suited to common straw hives, have it altered; for none other are so cheap or so well adapted to your purpose. The specimen you enclose is *Salvia argentea*, Silver-leaved Sage. Buckwheat forms excellent bee-pasturage, but should be sown in large quantities to be of much service. Situated as you are, however, there is little doubt of your bees doing well, and we should deem it labour lost to cultivate expressly for them. We have been told that in China they bury bees during winter, and also bury a dead fowl with each hive. When exhumed in the spring, the bones of the fowl are stated to be picked as clean as those of the small birds you mention!]

UNITING BEES—TAKING THE HONEY FROM PARTIALLY-FILLED COMBS.

I HAVE two "casts" so light that I doubt whether any amount of autumn feeding would carry them through the winter. If I unite them to other stocks, what shall I do with the brood-comb, if any, and what with any honey there may be in the other comb? The two stocks or May swarms of this year to which I propose to unite them, are in Stewarton-hives; what would be the best plan to adopt in carrying out my proposal? These swarms have filled only one box completely, and a second box but partially, what had I better do with these second boxes? Shall I leave them as they are, or remove them? and if the latter, what shall I do with any honey there may be in them? If the former,

would not the honey in them help to support the bees from the casts that I propose to put to them?

In the next place, I have some partially-filled combs in a glass super on a Woodbury bar-and-frame hive, how can I extract the honey out of them without breaking them up? Any information respecting the above would greatly oblige. Please to understand that I am quite a novice at bee-keeping, and regard my questions as the natural growth of necessary ignorance.—T. R. D.

[You are not likely to find any brood in either of your weak casts at this season. Whatever honey remains will be fit for table purposes, to which we should apply it. By cutting off the empty part of the combs in a straight line they may readily be attached to either bars or frames, and should be carefully preserved for use next season. Read Mr. Woodbury's articles on driving and uniting bees, in Nos. 139 and 144 of THE JOURNAL OF HORTICULTURE, and follow the instructions therein given.

We conclude that it is the lower compartment which is but partially filled in your Stewarton hives, and if so should leave them as they are.

The only method of appropriating the honey in partially-filled combs without breaking them up altogether, is to slice off the cells on both sides, leaving the central foundations uninjured, and fixed to the bars for future use. Our esteemed correspondent, "B. & W.," once informed us that by adopting this plan he had had the same combs filled thrice in one season.]

THE BEE SEASON.

THE summer of 1864 has been a very fine one for bees, but, in my opinion, inferior to the last, as the flowers were languishing in July for want of moisture. I have noticed, however, a great appearance of honeydew in August: this generally produces honey of rather a coarser character than from white clover or other fine bee pasture.—H. W. NEWMAN, *Hillside, Cheltenham*.

APIARIAN VARIETIES.

Foul Brood.—I was very sorry to hear of the apiary of "A DEVONSHIRE BEE-KEEPER" being so affected, and I have no doubt that it would have been entirely destroyed had it been in the hands of any one but himself; and for my own part I thank him for the straightforward manner which he gave it to the world. I have some experience and information on the subject, which I hope to communicate at some future opportunity.

QUEENS IN 1862.—In the first place, the great Dzierzon and "A DEVONSHIRE BEE-KEEPER" gave it as their opinion that a young queen would not take her wedding flight with the thermometer lower than 70° or 75°.* The low temperature at the time they should have been out gave rise to some misgivings and uneasiness on my part, as the sheet was as follows:—52°, 54°, 56°, for weeks; but on the 7th of July came a little sun, and the register was 60°. I was at my hives in an instant to see if any of the virgins would make their exit. In a few minutes No. 1 made her appearance and took wing, but returned in about five minutes unsuccessful, but stayed upon the edge of the alighting-board a few minutes and then took flight again. As near as I could tell she was about twenty minutes in returning, with evident signs of impregnation, and laid eggs in six days all right, with the thermometer at 61°. No. 2 was out at the same time; I did not see her return, but she had been successful, as her young ones were out at the same time as those of the other. She was in a straw hive, which I could not inspect. I should have said that No. 1 was twelve days after swarming, and No. 2 was nine days.

My next performance was with queens at the time of taking them up. I had some driven bees without a queen three days which became very uneasy, so I gave them one that had ceased breeding some months, and marked her. I gave her to them at the top without any preparation. They received her with the greatest kindness, and all was peace;

* I still hold to the same opinion. Was not your thermometer in the shade, and did it not therefore register a lower temperature than the sunny atmosphere which inclined the queens to hearken to the call of love?—A DEVONSHIRE BEE-KEEPER.

two hours after I gave them a young one in fine order. I anticipated the usual excitement, but all was peace. I expected to have one cast out, but no, and upon examination the unfruitful one had disappeared without any of the usual signs. These are facts—take them for what they are worth.

THE DISTANCE QUEENS AND DRONES FLY ON THEIR NUPITAL TOUR.—The introduction of the Italian stock to this district has enabled me to give some information upon this important subject. In the first place I must state that there is not one of the young queens from the Italian stock impregnated with an Italian drone, therefore all are cross-mothers; and, strange to say, out of twenty young black queens within half a mile of the old Italian stocks (the young ones removed), not one has been impregnated by the yellow bees, but at one mile up to three and a half miles distant thirty per cent are cross-mothers, and many of them are better marked bees than from the Italian queen with a black drone. I see that in another remove there is scarcely a trace left.—NORTH.

BEES IN SURREY.

As there are many readers of THE JOURNAL OF HORTICULTURE who, like myself, take an interest in anything relating to bees, I am induced to give you the results of my first manipulation, or deprivation of honey from my collateral-boxes.

In the first place, I live only four or four and a half miles from London; not one of the most open positions for an apiary, being surrounded with houses on all sides, and my bees having to go a long distance to collect their stores, consequently it takes a longer time to fill the boxes than it would do if placed in an open country. On the 6th of May I opened one of my collateral-boxes, No. 1, for the increasing population, and on the 20th of June I opened No. 2 box, to let the industrious labourers construct more combs. On the 16th of July, I took off box No. 1, which had all the cells sealed, except about half a dozen on one small comb, without a single grub, or egg, or brood in any stage whatever, which I attribute to the ventilation in my hives. Box No. 2 is three parts full, independent of the middle box or pavilion of nature, as Mr. Nutt calls it, which is quite full. On weighing box No. 1, I found it contained 20 lbs. of honey, after the box and wax had been deducted from it; and I have left in the other boxes 30 lbs. more. But, as the weather has been so dry, I find the bees do not collect so much honey; and, seeing your advice of August 9th to a correspondent, I consider it most prudent to let well alone, as the stock is very strong. I may perhaps ruin my hive for the sake of a few pounds of honey, which will not be wasted by the bees if they do not require it.—T. S.

CHARACTERISTICS OF ITALIAN BEES.

I WOULD state that the result of my experience regarding Italian bees, is, their disposition to labour far exceeds that of the common bee; they commence work earlier in the morning, and work later in the evening, and on a cool day, when the common kind are not to be seen they are at work. It seems that they prefer a northern clime, for in their native country it is said they are only found in the north, while the common bees are found in the south. The queens are larger and more prolific than common ones, and are inclined to swarm oftener and earlier. The Italian bee differs from the common one in being larger, and of a light chrome yellow colour, with light brimstone-coloured wings and two orange girths immediately behind the wings. Working bees as well as drones are thus marked, the girths upon the drones are scolloped, and they attain an astonishing size. The queens are marked a good deal like the workers, but much brighter, and on account of their size and colour, are very easily found in a swarm. The bees are almost transparent when the sun shines on them, and when bred in comb of their own building, are larger than when bred in comb of common bees, as their own cells are larger. I have proved beyond a doubt to my mind, that they will gather from one-third to one-half more honey than common bees. It is said of them that they will gather twice as much, but I only give them credit for superiority over the common ones, in so far

as I have proved from practical observation. They seem to gain the most on common bees, in the latter part of the season. It is said they can gather honey from red clover: I have not paid attention to this quality in them, and therefore, cannot speak of it from my own knowledge. Some of my neighbours have told me they have seen them gathering honey from it; if so, this will account in a great measure for their gathering more honey than common bees.

They are extremely amiable, as unprovoked they never sting. There is one trait in their character, which I do not admire much, although it proves their superiority, and that is their propensity for stealing; if there is a hive of common bees near that are weak they are almost sure to be robbed, and on the other hand, common bees find it useless attempting to rob Italians, as they can repel three to one. My experience with them is, they are superior in every way to common bees.—H. HOLDEN, Mirickville.—(Canada Farmer.)

DESTROYING WASPS.

YOUR correspondent from Dorsetshire inquires how wasps are to be destroyed. First of all, squib them with gunpowder where their nests are, and dig them out; almost an impossibility this season to find them all. I have found Millington's wasp-glasses very effective in a small way; they must be about one-quarter filled with brown sugar and water, or a little small beer. I have emptied these glasses generally containing from 100 to 200 wasps and one or two blue flies. If honey is used in the glasses, then the bees are entrapped in large numbers themselves; but when sugar and water and a little beer are used, I have never found a single hive bee caught, although the glasses are placed within 2 feet of the hives; and during the late hot dry weather the wasps seemed quite ravenous after liquid food.

I cannot quite approve of Mr. Taylor's mode of placing barleysugar; for, though it attracts the bees in numbers, they are a good deal too busy with the candied sugar to notice the wasps much, and I am inclined to think the offer of the sugar takes the bees off their guard. Mr. Taylor is, however, a steady apiarian in all other respects, and in his case probably the passage into the hive must have been quite blocked up by the bees.—H. W. NEWMAN, Hillside, Cheltenham.

TO PREVENT YOUR BREAD BEING BITTER.—Add a tea-spoonful of magnesia to the yeast just before you use it.—S. M.

OUR LETTER BOX.

USEFUL FOWLS (Ruby).—A Dorking cock with your cross-bred Cochins pullets, will produce short-legged, full-breasted chickens for table, and the pullets will lay in the winter.

WASHING THE PLUMAGE OF FOWLS (Cochin).—Buff Cochin plumage does not want washing. Silver-spangled Hamburgs should be washed with soap and water. The bird should afterwards be put in a basket with soft straw, and either placed in the hot sun, or before a fire, till the plumage is dry.

NANKIN BANTAMS.—A "CONSTANT READER" in No. 178 asks where he can obtain some of these birds. I had not seen any for years, until when passing through the village of Seagry last February I saw a considerable number of them in a field adjoining a pretty cottage. I only caught sight of them at a distance, and for an instant only, from the top of an omnibus; but I believe I am correct as to the sort. I understand the owner's address is—Mr. Sampson, Seagry, near Chippenham, Wilts.—WILTSHIRE RECORDER.

POULTRY-JUDGING (H.).—Before we insert your communication you will oblige us by furnishing us (not for publication), with the name of the Show and Judge.

PIGEON JUDGING AT NEWCASTLE AND DARLINGTON (A. B. C., and the Compiler of the Darlington Schedule).—Enough has been now said on the subject, and the gentleman who made the awards we should think is not likely to appear again as a judge of Pigeons. We would also remind our correspondents that attributing misdoings and bad motives only exasperate, and have nothing to do with the only question at issue—Were the Pigeons correctly judged?

DEFECTIVE RABBIT (C. O.).—Sell him or eat him, and buy another.

PREPAREDNESS OF WAX-HIVES (B. B.).—The kettle for rendering combs into wax could readily be manufactured by any tinsmith from the description we quoted from Dr. Bevan's work, but we know no one who keeps such things for sale. The hive figured in No. 178 is of Canadian manufacture, and is not obtainable in this country. We believe the Woodbury frame-hive, made by Messrs. Neighbour, possesses all its advantages, whilst it is better adapted for English use. The society you refer to has long been defunct.

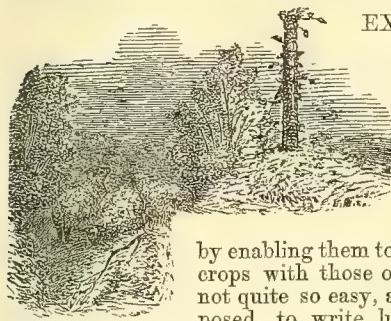

BORAGO FOR BEES (A. B.).—You may sow in September, and again in March or April, which will secure a succession of flowers. We are glad you have succeeded so well.

WEEKLY CALENDAR.

Day of M'nth	Day of Week.	SEPTEMBER 13-19, 1864.	Average Temperature near London.			Rain in last 37 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.	
			Day.	Night.	Mean.									
13	Tu	Golden Spurwort flowers.	67.8	45.9	56.5	17	34 af 5	18 af 6	44	4	10	2	12	4 19 257
14	W	Horse-Chestnut leaves change.	66.8	45.3	56.5	19	35	5	16	5	32	3	13	4 40 258
15	Th	Foxtail Oat Grass ripe.	67.2	46.5	56.9	19	37	5	13	6	44	5	17	5 1 259

18	SUN	17 SUNDAY AFTER TRINITY.	66.7	47.1	56.9	17	42	5	6	6	14	7	4	9 17 262
19	M	Goldfinches congregate.	66.8	45.4	56.1	18	43	5	4	6	52	7	20	10 18 263

From observations taken near London during the last thirty-seven years, the average day temperature of the week is 67.5° , and its night temperature 46.4° . The greatest heat was 84° on the 17th, 1843; and the lowest cold, 29° , on the 17th, 1840. The greatest fall of rain was 0.90 inch.

MY ORCHARD-HOUSE.—No. 9.

EXPRESSED in a former paper my conviction that a statement of the dates of fruit ripening in orchard houses would be of great value to amateurs as well as to gardeners,

by enabling them to compare their own crops with those of others. As it is not quite so easy, as is generally supposed, to write lucidly, and at the same time, on horticultural matters, I shall confine this paper, chiefly to these important subjects—orchard-houses—judging, however, even (one of the oldest in England)—have made great progress in the last few years, and are now in full flower, so to speak, in England.

To begin with the earliest Peaches. The Red Nutmeg, a perfectly valueless fruit, in four years only advanced five days, ripening on July 5; Petite Mignon, a delicious little Peach, but not worth cultivating, ripened on the 17th of July, gaining eleven days in four years; Early York, the queen of early Peaches, has advanced from August 1, in 1861, to July 4, in this year; Canary, American, from Georgia, has gained twelve days in three years, ripening July 11th; Golden Purple, also an American Peach, has advanced fifteen days, ripening on the 20th of July; Alice is nearly stationary; Acton Scott much the same, both being worthless for special use; Vineuse de Fromentin had gained thirteen days in three years, and again lost them by being changed to the late house (this fruit is unworthy of notice); Stump the World, a grand American, has only progressed three days in as many years, ripening August 15th; Honey, ripe August 10th, 1862, was ripe on July 21st of this year. Brugnon Imperial Nectarine, five days gain, ripe August 7th; Rivers's Orange has gained eighteen days, ripe July 28th; Du Tellier's, seven days, ripe August 9th; Duchess of Oldenburg, seven days, ripe August 9th; Chauvière, seventeen days since 1862, ripe August 11th. These are all fine fruits, and worthy of cultivation. Chauvière is especially good—large, well coloured, flavour aromatic, and bears abundantly. These dates are gathered, not from solitary specimens, for of some kinds we have ten or twelve in various forms of training. Stanwick Nectarine and Stanwick Seedling have advanced somewhat also, but not so as to form any opinion. Stanwick Seedling is a magnificent Nectarine, of the same flavour as the parent, and colours well; ripe, this year, August

17th. A most valueless Peach is the Chancellor: that has advanced ten days, but it is to be condemned. Walburton Admirable is nearly stationary; ripe August 30th. A handsome Peach, but too pale generally to please the dealers' fancy. Early Crawford was ripe July 30th. This very fine Peach is also out of favour with dealers. These pretend that only high-coloured fruit, like Royal George and Grosse Mignonette, are saleable. It is well that my brother victims should be aware of this, and also that all yellow Peaches are said to be at a discount. It is also "passing strange" that whenever any particularly valuable baskets are sent up the markets are at once "flooded with small fruit, or Peaches from the South of France;" so that we become public benefactors without intending it, even by means of these houses.

I come now to a point on which I feel somewhat perplexed. It is, that however agreeable and profitable it may be to have nice saleable July Peaches by reason of the house advancing their maturity, the same cannot be said when Peaches intended by Nature to succeed the out-door ones are forwarded so far as to become ripe at the same time. This is most disagreeable, and I have immense trouble to retard the ripening of the fruits. We have never extensively practised removing Peaches to a colder atmosphere so as to check them, because this requires care and time, so that I cannot speak of this plan. I find, however, the regular October Peaches gradually becoming mid-September ones. Pavie de Tonneux, for instance, ripe October 1st in 1861, October 4th in 1862, October 1st in 1863, is now ripe ! It is a splendid clinging-stone of grand shape and colour, reckoned second-rate in flavour in the best French catalogues, but very good by those who, like me, prefer clingingstones. Thomas's Late, a very great acquisition, sent me by Mr. Rivers, has advanced from October 8th in 1862, to October 1st in 1863. At this rate it may ripen by the equinox in a year or two. I place great dependance on Tardive d'Espagne for lateness, due October 10th; but even this has been removed to a cold corner. Baldwin's Late, another American from Mr. Rivers, ripened on November 2nd in 1862; but, alas ! on October the 20th last year. I fear we shall never have good November Peaches. The October ones are, however, really good, and among the new varieties soon to be introduced there may be more such.

soon to be introduced there may be more such.
From the foregoing rough sketch, from which many are omitted, it will be seen that the period of the fruit's ripening has really been accelerated, and this gradually, as could also be shown. No doubt, however, having a second house with a different aspect would remedy much of this evil; for it cannot be too often insisted on that it is in the succession of fruit that orchard-houses especially shine. All our out-door Peaches were gathered in three weeks. During that period there was much waste. A great many Peaches also fell in the houses from the violent winds, and the overcrowding of the trees rendering pruning very hazardous. Much wider houses would have been better in our case. A path round by the front is very useful.—T. COLLINGS BREHAUT, *Richmond House, Guernsey.*

BULBS.

CATALOGUES of Dutch and other flower-roots now making their appearance remind us that a few hints on the cultivation and the choice of bulbs may be useful to those who have had but little success in their management, or who wish to enjoy sweet and beautiful flowers in winter. I shall divide the subject into three parts—1st, Bulbs for forcing. 2nd, For flower-garden decoration. 3rd, Greenhouse and stove bulbous plants.

1st, BULBS FOR FORCING.

Of those none are more beautiful than the far-famed Guernsey Lily, and the not less beautiful Belladonna Lily (*Amaryllis belladonna*). The Guernsey Lily has a flower of the most brilliant scarlet imaginable, looking in the sun's rays as if dusted with gold, beautiful in the extreme, and appearing at a time when flowers are scarce—October and November. The Belladonna Lily has a charming whitish flower flushed with rosy purple. They should be potted at latest by the middle of September, before the scapes are too far advanced, or they are liable to be injured in travelling, and will not bloom finely. Three to five may be planted in a six-inch pot, providing efficient drainage, and employing a compost of good, sound, and rather strong loam, with a little sand intermixed. I usually insert them to the neck in the soil, and after watering them place in a cold frame on coal ashes until the first week in October, admitting air day and night, and protecting them only from heavy rains. When brought on in a warm house, and at a distance from the glass, they bloom poorly, and are not capable of supporting the beautiful flowers on account of the long flower-stem. To bloom well they should be kept near the glass, and have abundance of air, but no more heat than is necessary to exclude frost. A fair amount of air, but not drying currents, is essential to success, and not less so is a light situation. They do moderately well in sitting-room windows, and are beautiful objects for autumn decoration generally. Inserted in moss or cocoa-nut fibre refuse they bloom finely, providing it be kept moist; but the bulbs are of no use afterwards, nor are those potted after the flower-scape appears. To grow them and bloom them are two different things, of the latter of which I shall have occasion to speak hereafter.

Presuming them to have been potted early in September, I give enough water to keep the soil thoroughly moist, and place them in a cold frame, where they will require to be near the glass, and have a free circulation of air. By the last week in September the scapes will be far advanced for flowering, when they may be removed to a shelf in the greenhouse; and duly supplied with water, they bloom finely in October and November. Copious supplies of water are necessary to prolong the blooming. Those who have not grown these bulbs have a treat in store.

HYACINTHS.—Domestic flowers in every sense, thriving in the smokiest and busiest thoroughfares of towns nearly as well as they do in the best-constructed horticultural buildings, they are unsurpassed for their beautiful colours, form, and fragrance, and on this account they are deserving of every care, and ought to find a home in every household.

The first essential to their successful cultivation is the selection of bulbs, which should be clean, healthy-looking, and heavy and firm. It is desirable to choose those bulbs that have the scales covered with a thin tissue-like coat, passing over those with the scales perished for some distance from the crown, and having a cankery appearance. Round medium-sized bulbs are the best, and if they have the apex closely filled up with the scales, and the base of the bulb, from which roots are emitted, free from mouldiness, flat, but not much sunk, with a firmness to the touch and heavy for their size, these are the sort of bulbs. Some kinds, however, produce large roots, but even of such those bulbs having a firmness and heaviness, which the large open-scaled roots do not possess, are to be selected in preference. Large, loose, light bulbs seldom give close symmetrical flower-spikes, but have more foliage, and taller open spikes of bloom. Many kinds have smallish-sized roots, and these almost invariably afford the best spikes of bloom. It is also desirable to procure bulbs early, quite as much to secure them good as to have them potted in due time for an early bloom; and another grand point in ordering them

early is to obtain roots that have not been exposed, perhaps for weeks, to the influences of the atmosphere in the seedsman's shop or window. The exposure of the bulbs to light and atmospheric changes exerts an injurious influence upon them. After they are purchased it is desirable to keep them, if they are to be retarded, in the thin paper in which they are wrapped and in the bags, packed in chaff in a cool, not light, and dry situation. A warm place renders the roots liable to premature growth of top, and a moist one causes the emission of roots.

The next question is the choice of sorts; of these the single varieties give the largest spikes, and, unlike the double, invariably do well in water. Some consider the single varieties the most beautiful; but they might as well say a Dog Rose is superior to the best of the Hybrid Perpetual Roses. The single are the most numerous, which is only what might be expected; for double sorts are more difficult to obtain than single. I shall only give a selection of the very best. Those marked thus * are the best for early forcing and also for water; † fine for exhibition.

DOUBLE BLUE.

Laurens Koster, indigo; long spike; bells large and closely arranged.
Van Speyk, light blue, striped with deep blue; fine spike; very large bells.
*Paarlboot, pale blue; fine spike; large bells.
Pasquin, pale blue; fine spike; large bells.
*Comte de St. Priest, light blue; fine bells; large spike.
Biokberg, fine marbled blue; large bells, and charming spike. A good old variety, not yet beaten.
Garrick, intense deep blue; excellent spike; with large bells closely arranged.
Rudolphus, sky blue; good truss; bells fine, but rather thin.
Prince Frederick, porcelain blue, or lilac, shaded; large bells; but moderate spike.
Sir Colin Campbell, light shaded blue; immense bells; fine spike.
General Antick, light blue, a colour not much wanted; but amply compensated for by the fine spike and good-sized bells.
Bouquet Constant, porcelain blue; nice bells, closely set on a very good spike.
Othello, very dark, with a small spike, but large bells.

DOUBLE RED.

*Duke of Wellington, pale rose; large bells, finely set on a good spike.
†Jenny Lind, deep rose; nice bells; good spike.
†Milton, fine deep red; large bells, and good spike.
Czar Nicholas, rose; good spike; fine bells.
*Waterloo, pink at first, changing to deep red; nice spike and fine bells.
†Noble par Mérите, rose, striped carmine; large spikes and immense bells.
Groot Voort, pale rose; fine handsome bells; moderate spike. An old variety, not yet eclipsed.
*Princess Royal, good spike; fine bells of the loveliest rose, striped with deep pink.
†Koh-i-noor, fine salmon colour; and fine bells and spike, just what a Hyacinth ought to be in form.
*Bouquet Royale, deep rose, with a pink eye; good bells, and fine spike.
Regina Victoria, rosy pink; fine spike, and large.
†Susannah Maria, remarkably fine spike, well set with charming salmon rose bells.

DOUBLE WHITE.

*La Tour d'Auvergne, very fine pure white; large spike; nice bells.
Ne Plus Ultra, large bells and spike; but not so compact as desirable, nor equal to many others.
*Prince of Waterloo, exquisite; large bells and spike.
Sir Bulwer Lytton, a bad white with a purple eye; large spikes, and such monstrous bells—novel, certainly, but not a move in the right direction.
Anna Maria, another bad white, being but a blush with a pink eye; with a moderate spike.
Sceptre d'Or, good pure white; but only moderate spike and bells.
La Vestale, beautiful white, with a goodly spike; but bells below par.
Don Gratuit, good white; large bells, and nice spike.
†Triumph Blandina, blush, improved by a dark or deep pink eye; with nice bells and a good spike.
La Désse, white; moderate bells; fine spike.

The raiser of good double whites or good double Hyacinths of any colour would make a fortune, and I hope ere long to report an advance in the double varieties similar to what has taken place in the single kinds.

SINGLE HYACINTHS.

What a host! but not one too many, only let them be as good as General Havelock (black), Lord Palmerston (blue), or Robert Fortune (mauve); but no more of your lanky Pienemans.

SINGLE RED.—All are fine for exhibition.

Joséphine, brilliant vermillion, the best red to be found in Hyacinths; nice spike; fine bells.
Cavaignac, salmon, with deep rose stripes; fine bells, and large spike.
Howard, orange crimson.
Circe, pink, striped with carmine; bells of good substance, just what is wanted in double Hyacinths.
Madame Hodgson, pale pink; nice bells; and such a fine spike, the form being so beautiful.
Pelissier, scarlet; beautiful closely-arranged bells on an immense spike. Everybody will grow this when the price is lowered.

Sultan's Favourite, a very pale rose, which would be worthless but for the deep pink stripes, and the number of flowers on the large spike.
 Lady Sale, deep red, suffused with purple, and a light eye.
 Victoria Alexandrina, very large bells, of an intense crimson, neatly set on an immense spike.
 Queen Victoria, pale pink, bright red stripes; good bells, compactly arranged.
 Von Schiller, salmon pink; good in everything.
 Florence Nightingale, pale pink, with carmine stripes. Fine.

SINGLE BLUE.

Bleu Aimable, violet shaded blue; fine bells, beautifully arranged on an immense spike. Not a finer Hyacinth in cultivation.
 Bleu Mourant, fine bells and spike.
 Argus, blue, with white eye, the tube bright indigo; fine bells and spike.
 Charles Dickens, grey shaded with blue; large spike and bells, and so finely set as to be handsome.
 Leonidas, clear blue. Fine.
 Regulus, pale blue; fine waxy bells on a very fine spike.
 Madame Coste, deep blue; only moderate-sized bells, but fine large spike.
 Grand Lilas, azure blue, but rather pale. Very fine.
 Lord Palmerston, much in the way of Argus, not yet let out.
 Thorwaldsen, one of the best of forms, with the loveliest of marbled blue bells of immense size on a rather small spike.
 Porcelaine Sceptre, porcelain blue, deeply shaded. Good.
 Numrod, light blue; nice spike; fine bells.

SINGLE WHITE.

Queen of the Netherlands; fine bells on an immense spike. A fine white.
 Madame Van der Hoop, a very fine white; large bells and fine spike.
 Snowball, fine in form and substance, of the purest white, with large bells and spike. One of the finest Hyacinths out.
 Paix de l'Europe, charming white, so pure and decided; rather small bells, yet very closely arranged on an immense spike.
 Fair Maid of Denmark, a splendid white; large bells and fine spike.
 Alba Maxima, pure white; large bells, closely set on a large spike.
 Victoria Regina, fine white, and fine every way.
 Miss Burdett Coutts, creamy blush; large bells of good substance, and immense spike. A most beautiful kind.
 Gigantea, blush; would be nice bells (though large enough now) if the petals were wider, instead of peculiarly narrow; fine spike.
 Lady Franklin, blush; large bells on peculiarly long footstalks, forming an immense spike. First-rate.
 Grande Blanche Imperiale, blush, with rose stripes; fine bells; good spike.
 Seraphine, another blush, with narrow petals, but a number of bells sufficient to form an immense spike.
 Elfrida, beautiful creamy blush; large well-shaped bells, closely set on a long spike.

SINGLE BLACK.

General Havelock should be good, and it really is a magnificent purple changing to black, with fine closely-arranged bells, forming an immense spike. A fine Hyacinth, if not the finest in cultivation.
 Prince Albert, fine bells, closely set on a nice spike.
 La Nuit, deep purple black. Fine.
 Von Humboldt, purplish black, with white eye.
 Lamplighter, purplish black, with a white eye.

SINGLE YELLOW.

Ida, a really good yellow. Fine.
 San Francisco, deep yellow, charming.
 Victor Hugo, fine bells and spike, but not worthy the name it bears.
 Duc de Malakoff, straw, instead of yellow, with a stripe of lake on each segment. Very fine bells, neatly arranged on an immense spike.
 Aurora, straw again; the tube splashed with pink, the segments with pink of a deeper hue in stripes; smallish bells, yet forming a nice spike.
 Koning van Holland, creamy yellow, shaded with an orange all but red; moderate bells closely arranged on a fine spike.

All the Hyacinths named are first-class, and are as easy of management as commoner and next to worthless kinds. There are some, however, that are specially adapted for early forcing, as L'Ami du Coeur (single red), and a few others; but the majority of the single varieties may be had in bloom any time after Christmas by potting them sufficiently early, so that the pots become well filled with roots before they are brought into a house with any great heat. In my next article I shall proceed to the treatment of Hyacinths as regards soil, potting, &c.—G. ABBEY.

(To be continued.)

PACKING ORCHIDS FOR IMPORTATION.

"ORCHIDOPHILUS" will find all the information he requires by referring to page 8 of Mr. B. S. Williams's "Orchid Grower's Manual," published by Chapman & Hall.

Mr. Williams says, "Erides, Saccolabiums, Vandas, Angraecums, and similar plants that have no fleshy bulbs to support, are best imported after they have become established on flat pieces of wood, so that they can be nailed to the sides of their travelling case." In his opinion "Orchids should be sent away from their native country during the dry season, which is when they are at rest."

He has received "plants in good condition from India in close boxes packed in dry soft shavings, while on the other hand," he has also "seen many spoiled in that way," which he attributes "to their not being packed in a proper state."

I should think charcoal dust would not answer, as in consequence of its having a heating tendency (?) it would be injurious to the plants, causing them to sweat and rot.

Once more, to quote from Mr. Williams's interesting Manual. "The best time of year for receiving Orchids in this country is, if possible, the spring, in order that they may have the summer before them to get established."—W. B. d'A., West Moulsey.

REMOVEABLE GREENHOUSE.

THE following is in answer to "HEREFORD," who wants a moveable greenhouse, span-roofed, 22 feet long, 14 feet wide, and asks questions accordingly.

Had it not been for the words "span-roofed greenhouse" we would have recommended Sir Joseph Paxton's houses for the million. For a house, however, of the usual shape—say the above length and width, and 6 feet high at the sides, and 11 feet at ridge, we would proceed as follows:—Obtain three pieces of oak $4\frac{1}{2}$ inches square, 14 feet long, and lay them across, one at each end, and one in the middle, on ground well firmed, and coated with tar. These will form the foundation, and keep the house from spreading. On the sides fix pieces of timber 4 inches square, and on these and the two end foundations fix studs, of the necessary height at the sides to reach the wall-plate, every $3\frac{1}{2}$ or $4\frac{1}{2}$ feet apart. Connect the two plates, by rafters, with a double ridge-board, 10 inches between them, and the skeleton of the house is finished. Screws well greased should be used instead of nails. Sashes to be fixed in the same way, front sashes also; and all sashes fixed. Sides and ends to be formed of wood and glass—wood say $2\frac{1}{2}$ to 3 feet high all round, of one-inch board, screwed to studs, and for safety two-inch thin pieces screwed along the joints. Ventilation should be given at the sides by shutters or wood flaps; at top by swinging-boards, between the double ridge-board, and rain prevented from entering by a cowl above with open sides. The three sleepers for the side sills to be below the ground level, inside; the centre table or stage to be made in separate pieces and moveable, from 5 to 6 feet wide; path all round to be from $2\frac{1}{2}$ to 3 feet wide, side shelf $1\frac{1}{2}$ foot wide all round, except at the doorway. The hot-water pipes should be beneath the shelf, or small stage, the shelf supported by brackets on upright studs in front, and small columns in line with the pathway. Heating may be effected by a small portable cylindrical boiler placed inside at the coldest end, and a small space shut off to prevent any dust getting to the plants or lighting the fire, clearing out ashes, &c. For common things a good iron stove would do all that was needful, but the boiler and pipes will be better. Nothing should be sunk in the ground, lest it raise a landlord's question.

VISITS TO GARDENS PUBLIC AND PRIVATE.

MESSRS. PAUL & SON'S, CHESHUNT.

LONG ere the Rose became, as it now is, everybody's flower—when Hybrid Perpetuals were unknown, and the floricultural world had not been taken by storm, as it has been, by generals, dukes, fair dames, princes of the blood, &c.—Rivers, Wood, Lane, and Paul were names ever associated with the Rose; and even now, when the number of growers for sale has been so largely added to, and rosarians abound, these names still retain an honoured position. One feels in going to them that there is all the difference between these and many of their competitors that there is between one of the venerable churches of our land and a spick and span new one built after the designs of Gilbert Scott. The one may not be quite in order, there are things that continually remind you of age; but despite of the trim neatness of the new, the faultlessness of its architecture, the brilliancy of its appearance, you rather like the old better. It was with somewhat of this feeling that I a week ago found myself on the way to fulfil an oft-repeated invitation to visit Mr. Paul at Cheshunt. Having a few hours to spare ere leaving for Colchester, I trusted myself to the tender mercies of the Great Eastern Railway, and reached my destination on one of the hottest days we have lately had. I did not, of course, expect to see much; the long-continued drought

had, I knew, prevented much second growth; and consequently the bloom of Roses, I knew, must be very defective, few in number, and, after what I had seen, hardly worth looking at: but there was really more than I could have expected.

The nurseries of Messrs. Paul & Son, which adjoin the pretty little village of Cheshunt, comprise about fifty acres, a large portion of which is allotted to the usual general stock of a nursery—fruit and forest trees, shrubs, &c., and about ten or twelve acres are devoted to Roses. The soil on which these are grown is of that rich unctuous loam which the Rose delights in, and which we in vain try to imitate, and to which mainly are to be attributed the magnificent blooms that have been exhibited by this eminent firm during the past season. It must be borne in mind, however, in comparing the stands of nurserymen with those of private growers, that the great advantage that the former have is in the possession of what are technically known as dormant buds. These are those buds which, having been inserted in the summer or autumn, have not started, but in the spring shoot out. They are allowed to throw up their terminal cluster of bloom, and both in size and brilliancy far exceed those which are cut from older plants.

The season is a very unfavourable one for autumn blooms; but I noticed amongst kinds freely in flower Maréchal Vaillant, a flower not nearly so well known as it ought to be; Madame Caillat, of which the same may be said—it is large, fine in shape, and good in colour; Alfred de Rougemont, one of the best of last year; Lord Clyde, there was a very fine piece of standard plants of this, and next to Charles Lefebvre it is, perhaps, the best dark crimson Rose we have—it is, like that noble flower, very strong in constitution and vigorous in habit, and the number of fine blooms at this time testified to its value as a perpetual-blooming Rose; Baron Gonella, a splendid Bourbon, rarely ever failing to give a fine bloom at all seasons; Olivier Delhomme, a beautiful bright flower; Alphonse Damaizin, excellent; Vicomte Vigier, very free-blooming, but at times somewhat thin; Vainqueur de Goliath, fine; Madame Julie Daran, either the plant I had of this was not correctly named or my soil does not suit it, for I have seen it so fine in so many places that I must withdraw my judgment against it and put it down as an A1 Rose; Lord Canning was also well in flower, but Mr. Paul hesitates as to letting this out as a new Rose, for it is somewhat flimsy in the petal, and he has therefore decided on not propagating it further, but will put it into his catalogue, and it may possibly happen that it will be better in some localities and seasons than it has yet proved to be; Lord Macaulay, an excellent dark Rose; Madame William Paul, curious in its shading, and likely to be a useful Rose; Lady Emily Peel, small, but will be in request for its shape and colour; Baron Adolphe Rothschild, a bright and excellent flower, far before the other Baron de Rothschild.

We had a talk over the new Roses, some of which were in bloom, and our conclusions were very much of the same character—viz., that they were a very indifferent lot, while there were a few good flowers amongst them. The best of these were Pierre Notting, a well-built dark crimson flower, with a bright scarlet hue through it; Claude Million, crimson scarlet, which I also saw good in Paris; Kate Hansburg, a bright pink; Madame Derreulx-Douville, bright rose colour with lighter edge to the petals, another flower I saw very good in Paris with Leveque who sent it out; Bernard Palissy, bright reddish carmine; Madame Victor Verdier, cherry red, very deep and excellent; and Bourbon Rev. H. Dombrain, very brilliant and good. These form the cream of the whole collection of last year; and it will be seen that there is a very large quantity of "skim milk" left. There must be an end to this; and if the English Rose-growers are resolute in the matter the inundation of rubbish will soon come to an end.

Besides the Roses in the open ground there is a very nice Rose-house, in which all the best varieties of Teas are planted out, and which must in the proper season be a most enchanting sight. The plants now looked very healthy, and gave promise of doing well next spring; nor have I ever seen a finer house of Vines in pots than there was here. The canes were all vigorous, well set with fruiting-buds, and as they were grown in a small span-roofed house, and

only one row on each side, every encouragement to their growth was given them, which they amply repaid by their vigour.

In the greenhouses there was not, of course, at this season much to see; but Mr. George Paul's treatment of that pretty autumn-flowering Amaryllid, *Vallota purpurea*, has been very successful. He showed me a quantity of bulbs which were last year very small, but which were now throwing up two and three stems of bloom, while small offsets of last year were now blooming strongly. This desirable result has been obtained by simply growing them well from the time of blooming. As soon as that is over the stems are cut down as low as possible, the bulbs are repotted, and then as they fill the pots with roots are again repotted, and kept growing all through the winter and spring. When they begin to show their flower-stems they are removed into the greenhouse, and contribute greatly to its gaiety. It ought certainly to be extensively grown for this purpose.

There is here, also, a very nice collection of Hollyhocks, for which the season seems to have been especially favourable, the blooms having been finely developed, although it has been necessary to mulch and water liberally. Amongst the most remarkable varieties I noticed Jules Margottin (a seedling of Messrs. Paul's), Morning Star, Lady King, Stanstead Rival, Omega (a fine seedling of Mr. Roake's, to be sent out by the Messrs. Paul), Joshua Clarke, Lord Clifton (Lane's), Lady Dacres, Invincible, Beauty of Mitford, and Hesperis (this more curious than pretty). The soil seems here to suit the Hollyhock admirably, and a fine and noble-looking flower it is.

As I had to return to town early, so as to get down to Colchester in the evening, my visit was a hurried one; but I was much gratified with all that I saw, and have no doubt that the Cheshunt Nursery will maintain the high position it has held for so many years.—D., Deal.

THE ROYAL HORTICULTURAL SOCIETY'S AUTUMN SHOW.

THIS was announced to take place on the 7th, the same day as that selected for the Crystal Palace Show, and on the fact being discovered or pointed out the date was changed to the 6th; but the result was much as we predicted, for the display was meagre, and the attendance of visitors certainly less than a hundred.

For Roses there were three classes, and three exhibitors came forward—viz., Messrs. Paul & Son, Rev. W. F. Radcliffe, and Mr. Treen, of Rugby. The first-named had first-class certificates for twenty-four and eighteen. Mr. Radcliffe had a second-class certificate for twenty-four, and Mr. Treen first for twelve, and second for eighteen. We noticed good blooms for the season of the year of Triomphe de Caen, Senator Vaisse, Marechal Vaillant, Gloire de Dijon, Solfaterre, Jules Margottin, and Celine Forestier, the best coming from Messrs. Paul.

Of Hollyhocks there were two classes; and in each the only competitors were Messrs. Minchin & Son, of Hook Norton, Oxfordshire, whose flowers were remarkably fine. The most noticeable were Argentea, Royal White, Gem of Yellows, Pericles, Beauty of Mitford, Emmeline, Princess of Wales, not large, but a pretty rosy pink; Rev. Joshua Dix, fine crimson, and of great substance; Queen Victoria, rosy carmine; R. B. Ullett, fine deep crimson; and Invincible, buff-tinted rose. Stanstead Rival was also large and fine. Messrs. Minchin well deserved the first-class certificates which were awarded them, both for their stand of twenty-four and twelve.

Of Gladiolus, Messrs. Paul & Son contributed a good box of twenty-four, among which Brenchleyensis well maintained its position for brilliancy of colour. Of the others the most showy were M. Vinchon, scarlet; Stephenson, crimson; Victor Verdier, fine bright scarlet; and Mathilde de Landevoisin, flesh, with a purplish streak in the throat. Mr. Treen also sent some excellent spikes, but unnamed.

Of Verbenas, Messrs. Minchin sent a very good stand, comprising Foxhunter, Géant des Batailles, Grand Eastern, Princess of Wales, pale blue, white eye, and Mrs. Moore, deep blue with distinct white eye.

The only exhibitor of Dahlias was Mr. Keynes, of Salisbury, who exhibited in all the nurserymen's classes, and his blooms, as usual, were excellent. In his stand of thirty-six were—White: Mrs. Piggott, and Miss Henshaw; Yellow: Queen of Primroses, Fanny Purchase, and Golden Drop; Orange and Buff: Hugh Miller, Willie Austin, Pauline, and Norfolk Hero; Crimson, Maroon, &c.: Donald Beaton, Andrew Dodds, Garibaldi, and King of Sweden. In other stands from the same exhibitor were fine blooms of Criterion, Lilac Queen, Charlotte Dorling, Anna Keynes, blush white, John Wyatt, rosy purple, besides others already named. The three stands of Fancies from Mr. Keynes, were also very good. In the Amateurs' classes there were no exhibitors.

Of other objects, Messrs. Paul & Son contributed Asters; Messrs. Smith, Dulwich, some fine Balsams; and Messrs. A. Henderson & Co., a collection of new plants, including three kinds of Campylobotrys, a large plant of *Cissus porphyrophyllus*, *Rhododendron javanicum* in flower, *Jacaranda flicifolia*, which deserves to be more extensively grown on account of its graceful fern-like leaves, *Musa zebrina*, and some other ornamental-foliaged plants.

THE CRYSTAL PALACE AUTUMN SHOW.

SEPTEMBER 7TH AND 8TH.

FOR the extent of the display and the numerous attendance of the visitors who inspected it, this Show yielded to none of its predecessors held at the same season and place. Though necessarily less varied than a summer show, the display was equally extensive, and the quality of the productions was excellent. The objects exhibited occupied a double line of tabling running the entire available length of the nave, of which one half was devoted to flowers and the other to fruit.

The main features of the floral department were Dahlias, Hollyhocks, Gladiolus, and Asters, the entries of the former being extremely numerous, and there was scarcely a stand which was not highly creditable to the exhibitor. The size of the blooms, however, was, as a general rule, not equal to last year—a circumstance which is easily accounted for by the long drought which has prevailed all over the country, and in contending against which the growers must have in many instances had great difficulties.

DAHLIAS.—In the Nurserymen's Classes Mr. Turner, of Slough, and Mr. Keynes, of Salisbury, as usual, carried off the principal prizes with splendid blooms of the best varieties. The former was first in the class for forty-eight blooms with, among others, excellent examples of *Mirfield Beauty*, *Golden Admiration*, *Emma*, *Chieftain*, *Willie Austin*, *Madge Wildfire*, *Charles Turner*, fine colour, yellow tipped with crimson, *Lady Popham*, *Andrew Dodds*, *Leah*, a fine new yellow, and *Princess of Prussia*. Mr. Keynes was second, Mr. Walker, Thame, third, and Mr. Legge, Edmonton, fourth; the stands of all being good, and, it is almost unnecessary to add, that of Mr. Keynes being particularly so.

In the next class for twenty-four blooms, Mr. Keynes was first with a fine stand, in which we noticed *Golden Drop*, *Criterion* which is generally good, *Andrew Dodds*, *Miss Henshaw*, one of the best if not the best white, *Charlotte Dorling*, a very fine flower, *Norfolk Hero*, *Pauline*, *Baron Taunton*, *Hugh Miller*, &c. Mr. Turner here came in second with, among others, *Chairman*, *Miss Henshaw*, *Cygnet*, a beautiful white, *Emma*, *Andrew Dodds*, *Imperial*, *Lord Derby*, *Lord Palmerston*, &c. The other prizes in this class were awarded to Mr. Walker, Messrs. Kelway, Langport, Somerset, Mr. Morse, Epsom, and Messrs. Saltmash, Chelmsford, in the order in which they are named.

In the Amateurs' Class for twenty-four, Mr. C. J. Perry, Castle Bromwich, was first with a fine stand comprising many of the kinds already named; Mr. J. Sladden, Ash, second; Mr. T. Hobbs, Lower Easton, third. In the next class for twelve, Mr. Sladden was first, Mr. Charlton, Kibworth, second, and Mr. Hopkins, Brentford, third.

Among Fancies we observed excellent blooms of *Queen Mab*, *Lady Paxton*, *Pauline*, *Countess of Shelburne*, *Sam Bartlett*, *Baron Alderson*, *Madame Lemmens Sherrington*, *Norah Creina*, &c. In the Nurserymen's Class Mr. Keynes was first, Mr. Turner second, Mr. Walker third; and in that

for Amateurs, Mr. Sladden, Ash, and Mr. C. J. Perry occupied similar positions.

A few seedlings were shown, the best being *Spitfire*, orange red, from Mr. Rawlings; *Leah*, yellow, from Mr. Turner; and *Princess Alexandra*, yellow and orange, with deep scarlet markings; to all of which first-class certificates were awarded.

ASTERS.—Of these there was a good show, both quilled and tasseled. Mr. Sandford, gardener to T. Thomassett, Esq., was first in both classes; and the second prizes were taken by Mr. Betteridge for quilled, and Mr. Ward for tasseled.

ROSES.—The season was too far advanced to expect much from these, nevertheless, some good blooms were shown, the best being *Gloire de Dijon*, *Louise de Savoie*, *Celine Forestier*, *Victor Verdier*, and *Gloire de Santenay*. Mr. Turner, Messrs. Paul & Son, and Mr. Exell were first for 36, 24, and 18 respectively.

HOLLYHOCKS though not exhibited in such numbers as might have been expected, were shown in excellent condition. The most noticeable varieties were, Rev. Joshua Dix, a beautiful crimson, of fine form and substance; Stanstead Rival; Mrs. F. Mackenzie; Mrs. B. Cochrane; Lord Loughborough; Empress Eugénie, a beautiful white; *Lilac Perfection*; Invincible; and Prince Charlie, very fine colour. In the class for 24, Mr. May, Bedale, was first; Rev. E. Hawke, Willingham Rectory, well known as a successful cultivator and improver of this flower, second; and Messrs. Minchin & Son, third. For 12, Mr. Smail, Norwood, was first; and the Rev. E. Hawke, second.

VERBENAS.—The best stands of these came from Mr. Perry, of Castle Bromwich, who took both first and second prizes; and from Mr. Turner. The pipes were fine, and the varieties included such acquisitions as *Lord Leigh*, *Fox-hunter*, *Grand Duchess*, *Mauve Queen*, &c. Mr. Perry likewise contributed his seedling *Snowball*, which fully justified the high character given of it at page 68, and Charles Turner, blush white with rosy purple eye, both of which deserved and received first-class certificates.

GLADIOLUS.—The splendid collection of Mr. Standish, of Ascot, was one of the most attractive features in the Show; and in the size of the spikes, the brilliancy of the colours and number of the varieties exhibited was unequalled. One variety, *Eleanor Norman*, with a large flower, white and delicate pink, attracted much attention on account of its beautiful colours; Dr. Hogg, deep scarlet with a violet tinge in the throat; *Aurelian*, *The Ensign*, *The Colonel*, *Rembrandt*, *Stephenson*, *Calypso*, and others, were also fine. Messrs. Kelway & Son took the second prize, and in the class for 24 spikes, first; Mr. Standish being placed second. There is one point which deserves remark, it is, that Messrs. Kelway's spikes were supported by *Yucca* leaves at the back, a mode of showing which should be discouraged as being unnatural, and not exhibiting the foliage.

MISCELLANEOUS.—Messrs. Veitch contributed a collection of new and rare plants, including the curious scarlet-spathe *Anthurium Schertzerianum*, and a good collection of Asters in pots; Mr. Linden sent *Rogiera gratissima* and other plants lately exhibited at South Kensington; Messrs. F. and A. Smith, Balsams; Mr. J. Fraser, *Heliotrope Surpasse Guascoi*, a vigorous-growing kind with large trusses of flowers; Messrs. Downie, Laird, & Laing, *Amaryllis reticulata superba* with very pretty rosy pink markings; also, new *Pentstemons*, already reported on, and spikes of seedling Hollyhocks, of which *Reine d'Or*, yellow; *The Queen*, blush white; and *Monarch*, crimson, were very promising. Indian Yellow and some others of Mr. Beaton's new Geraniums were shown by Mr. W. Paul.

FRUIT.

The best collection came from Mr. Henderson, of Trentham, and comprised a fine Cashmere Melon, *Trebbiano* and Black Hamburg Grapes, Peaches, Nectarines, Apricots, and Plums. The second best was from Mr. Dawson, and consisted of a Pine, Barbarossa and Muscat Grapes, Morello Cherries, Washington Plums, Peaches, Nectarines, and Pears.

Pine Apples were very sparingly shown, some were not in good condition, and two or three had lost their crown. The first and second prizes for Queens were withheld, and Mr.

Stafford had the third. The best fruit of Any other variety was a Providence of 10 lbs. Mr. C. Smith, Norwood, took the second and third prizes in the same class. Mr. Drewett, Denbies, exhibited a curiosity, being a hen-and-chickens Pine from Penang, having a double crown and seven small Pines coming from the base, the whole weighing 4 lbs. 2 ozs.

GRAPES, though not shown in such abundance as we expected, were in some instances in great perfection, Mr. Meredith, as usual, taking the lead. In the class for boxes of not less than 12 lbs. weight he was first with large and beautifully-coloured Black Hamburgs; Mr. A. Henderson and Mr. Wills, Oulton Park, being second with Lady Downe's in fine condition; and he was again first in the class for the best three bunches of Black, his Black Hamburgs being of the extraordinary weight of 11 lbs. 4 ozs., the bunches remarkably compact and dense, and the berries finely coloured. Mr. Ford was second, and Mr. Omant third with good bunches of the same kind.

In White Grapes Mr. Dwerrihouse was first with splendid bunches of a seedling variety, the berries of which had an amber tinge, and the largest bunch must have been a foot long and 8 inches across at the shoulders. Mr. Budd, Cobham Hall, was second with well-coloured Muscats; and Mr. Wills third with Trebbiano.

For the largest bunch of any kind, Mr. Meredith was again first with Child of Hale, noticed some time ago in our Fruit Committee Reports. This was a magnificent bunch of 8½ lbs. Mr. Dwerrihouse was second with his seedling weighing nearly 5 lbs., and Messrs. Lane & Son third with Muscat Hamburg 2 lbs. 3 ozs. Marchioness of Hastings from Mr. Henderson weighed 4 lbs. 14 ozs., but was not ripe.

PEACHES AND NECTARINES were not generally large, a result of the season. Of the former, the principal varieties were Barrington, Royal George, Noblesse, Grosse Mignonne, and Violette Hâtive. Mr. Cross, Alresford, was first with Barrington, very fine; and second with Royal George; Mr. Spivey third with Monstrueuse de Doué.

Of Nectarines, the kinds shown were Elrige, Violette Hâtive, Pitmaston Orange, and Red Roman. Mr. J. Fraser, Lea Bridge, took the first prize with Murrey; Mr. Henderson second with Violette Hâtive; and Mr. Woodward third with Pitmaston Orange.

MELONS were extensively shown, and many of them were very fine as regards size and appearance. Scarlet Gem was almost the only kind shown in the Scarlet-fleshed class; and in the Green-fleshed, Golden Perfection, Golden Drop, Trentham Hybrid, and Hybrid Cashmere were the principal. Mr. Young, Havant, was first; Mr. Blair second, and Mr. Godfrey third, all with Scarlet Gem; and in the other class, Mr. Bailey, Shardeloes, was first with Bailey's Gem; and Mr. Rust second with Bromham Hall.

CHERRIES are now generally over, but several good dishes of Morello were shown. Mr. Dawson, Panshanger, was first with that kind and Belle Magnifique; Mr. Holder, Reading, second with Morello and Flemish, very good; and Mr. Bailey third with Morello and Bigarreau.

PLUMS were both numerous and fine. Coe's Golden Drop, Washington, Jefferson, Magnum Bonums, Goliath, Kirke's, and Denyer's Victoria were shown in excellent condition. The first prize was awarded to Mr. Bailey for Jefferson and Washington, beautifully coloured; and Prince of Wales, which is generally considered a second-rate fruit. Mr. Woodward was second with Nectarine, Jefferson, and Denyer's Victoria; Mr. Kaile third with the first two and Washington.

APPLES, both for dessert and kitchen use, occupied a great extent of tabling, but though mostly well grown were not remarkable for their size. Of the former, King of the Pippins, Kerry Pippin, Ribston Pippin, Blenheim Pippin, Cornish Gilliflower, Red Astrachan, and Devonshire Quarrenden (both finely coloured), Cox's Orange Pippin, Cellini, and Fearn's Pippin were the principal kinds. Messrs. Lane, St. Mary's Cray, took the first prize with Colonel Vaughan, Red Astrachan (beautifully coloured), Kerry Pippin, Cellini, Fearn's Pippin, and Maynard's Bearer. Dr. Cooper was second; Mr. Webb, Reading, third. In kitchen Apples, Hawthornden, Alexander, Keswick Codlin, Catshead, Blenheim Pippin, Golden Noble, Kentish Fillbasket, Lord Suffolk, and New Hawthornden were numerously shown. The

first prize in this class also was taken by Messrs. Lane, St. Mary's Cray, with Alexander, Blenheim Pippin, Keswick and French Codlins, Catshead, and Summer Tambour, all of which were fine. Mr. Mortimore, gardener to A. Smee, Esq., Carshalton, was second; Mr. Wren third.

PEARS were likewise very numerous, but did not present anything very remarkable. As might be expected Williams's Bon Chrétien, Louise Bonne of Jersey, Duchesse d'Angoulême, and Beurré d'Amanlis were the predominant sorts. The first prize for three dishes was awarded to Mr. J. Wilson, gardener to Sir R. Howard, Fulham; the second to Mr. Fraser, Lea Bridge; the third to Mr. Nicholls, Hammersmith. The heaviest single dish was shown by Mr. Dwerrihouse, the kind being Grosse Calebasse, which we have seen much larger. Uvedale's St. Germain, from Mr. Goldsmith, weighing 10½ lbs., was second; Catillac, 7½ lbs., from the same, third. The best dish for flavour was Louise Bonne, grown in an orchard-house by G. Wilson, Esq., Weybridge; Williams's, from Mr. Heather, Ember Grove, being second.

MISCELLANEOUS.—Excellent pot Vines came from Messrs. Lane & Sons, Berkhamstead; Mr. Giers; and Mr. W. Paul, the latter being exhibited to show the comparative time required for ripening the different varieties, all being placed under glass at the same time, the middle of April. Peaches, Apples, and Pears in pots were sent by Mr. Fraser; Figs, Cherries, &c., by Messrs. Lane; the fruit of Passiflora edulis by Mr. Scorer; Granadillas by Mr. Blair; large and fine Oranges by Mr. Hutcheson; good Red and White Currants by Mr. Milton; Apricots by Mr. Henderson; Cob Nuts and Filberts by Mr. Webb, Reading; and Capsicum, 3½ inches long by 2½ to 3 in diameter, by Mr. Scorer. Lastly, a beautiful wax-like dessert Apple, varying in colour from rose to carmine, came from Mr. Taylor, Nursling, Southampton.

EARTHING-UP CELERY.

ABOUT half a score of correspondents have written wishing for a short account of the reasons why we disapprove of the general directions in standard works, "Keep putting a little earth to the Celery in dry weather." In other words, why we disapprove of this frequent bit-by-bit earthing-up. Our reason, which applies to early Celery chiefly, is simply this, that the bit-by-bit system of earthing-up is just the best means for securing what we do not want, bolted Celery—that is, plants running and throwing up their flower-stalks, when they are deemed unsuitable for sending to table.

The Celery is naturally a ditch or swamp plant, and as such rejoices in moisture. Few plants in a kitchen garden need an equal supply of moisture. When it can be had, a short time before earthing-up, therefore, most people give a good watering. Some days afterwards, and when dry overhead and the leaves are dry, they give the plants 3 or 4 inches of earthing-up; in a week or ten days a little more, and at another interval a little more. If a good rain does come, it will not penetrate more than an inch, if it does for a quarter of that depth. Provided the weather is sunny the large leaves soon exhaust the moisture given at the roots before earthing-up. They can get no more unless what falls in the shape of dew or rains, which merely affect the foliage, not the roots. Hot sunny days continuing, the leaves throw off moisture by evaporation as long as they receive a supply; and at last, when from the demands made upon them the roots are pretty well as dry as if they were in a fresh ash-heap, the plants in self-defence and for the purpose of perpetuating the race, throw up their flower-stalk as a reproach to us for want of thought and consideration. We thus treat the Celery as we would any other plant we wish not to grow fast, but to flower and seed quickly—namely, we curtail the root-action, and deprive the roots of the moisture necessary for vigorous growth. We could hardly adopt a better plan than we do with the Celery if we wished a Cabbage, a Cauliflower, or a Turnip to bloom prematurely, instead of to grow vigorously, only the Celery is naturally more sensitive to dryness.

On the other hand, suppose the Celery plants are growing to a nice size, we go over them, pick out all suckers, and remove all bad leaves, and then after watering, and the plants have got over this doctoring, we tie each plant with

a band of matting—say 6 or 8 inches from the soil, not firmly, but sufficiently so to cause the leaves to stand upright round the heart of the plant, and so firm as by the very tying to commence the process of blanching. Then, if necessary, we water again. If it is dry weather, and we do not want to earth-up, we may scatter from half an inch to an inch of soil over the bed or rows, to keep the moisture in, and this may be repeated if necessary. For our first Celery we earth-up after such watering from twenty to twenty-five days before we want to take it up, doing the most of this earthing-up at once, and earthing only a little at a time for early use, as if too much is done the roots would be too dry in sunny weather from the evaporation from the leaves. As autumn goes on, when, after the middle of October, it matters less how the earthing-up is performed, as done it must be early, to secure the Celery against frost, by some means or other. But then evaporation is reduced to a minimum—nay, the leaves by the end of that month will absorb as much as they perspire, and, therefore, there will be no danger of the roots being kiln-dried. We could say little more were we to write a volume on the subject.—R. FISH.

A GOOD EXAMPLE.

[We have not space to spare for reports of what occurs at the very numerous village horticultural societies of our land; but we must publish a portion of the sayings and doings on the 27th of August, in a remote parish of Ireland. If similar associations, fostering the love of home, the beautiful, and the useful, were established throughout that land of vast capabilities, it would be a powerful agent for its improvement, and the "shillelagh" would more generally become a hoe-handle, and benefit by breaking clods oftener than heads.]

THE KILSKEERY GARDENING SOCIETY.

In the parish of Kilskeery the want of a society which would act as a stimulus to the people in the cultivation of gardening has long been felt, and it was to supply the deficiency that a society has been formed in the parish, which would incite its farmers and cottagers to pay greater attention, than they have hitherto done to the cultivation of their gardens. Having that in view a Horticultural Society has been established in the parish, under the patronage of the estimable Rector, the Rev. John Grey Porter, and Mrs. Porter, who gave every encouragement to the project, and the first exhibition of the season was held in the petty sessions court, Trillick. The show of flowers and vegetables was considerable in amount, and taking into account that they came from the gardens of the small farmers and the cottagers in the parish, they reflected the greatest credit on their producers. The show altogether was excellent, and gave evidence of a promising future for the Society.

The Rev. Mr. Porter, at the request of the Committee, presided.

The Secretary, Mr. Fitzsimons, read the list of prizes, and the Rev. Chairman rose and said, that by the favour of the Committee he had been called on to preside upon that occasion; and as that was the first show of their Society, he thought it his duty to mention a few things to them connected with its establishment. They were all aware the parish was inhabited by a most industrious, decent, orderly, and intelligent community, that they had neither grand jurors among them nor resident landlords, nor had they anything to look to but their own resources; and deprived as they were of all the advantages which the neighbouring parishes possessed, for there was scarcely a gentleman resident among them who kept a gardener for the purpose of encouraging horticulture, he (Chairman) felt proud at what he saw exhibited that day (applause). He had had an opportunity of going round the room and examining the entire exhibition, but the majority of those he had the honour of addressing had not time to do so, and he hoped they would all examine the whole display, and above all look at the beautiful flowers that were placed all round them. There was a horticultural society in the county Fermanagh, which lately held a show of flowers. He was not present at it, but on reading in the newspaper the list of prizes, he found that they generally went to my Lord Erne, my Lord Enniskillen,

and a gentleman who resides in the Palace at Clogher, of the name of J. Ellison Macartney (a laugh). What good did the granting to those gentlemen—who might have the fruits of their gardens placed on their tables—of prizes do the honest fellows whom he felt proud to be addressing on the present occasion? He wanted to have the tastes of the peasantry improved, he wanted to have their minds elevated and enlarged, in order that they should fully appreciate and enjoy all that was beautiful in nature. Let the grandees settle their affairs amongst themselves, but he hoped that with the people's help—and he could do nothing without them—and the help of the ladies, to have annually in the room they were assembled in, such a meeting as he had the pride and pleasure of presiding over on that day (cheers). Flowers were said to be the toys of the rich; but they were also, as he conceived, the friends of the poor. It was impossible for any person to cultivate a flower and not look up with thankfulness and joy to God who had made that flower (hear). He had been reading the other day a little book written by Dr. Mayhew, that on one occasion a missionary went to a district called Bloomsbury, in the neighbourhood of the Seven Dials, in London, where he visited a poor old woman who was living on the parish allowance of 2s. 6d. a-week, and she felt delighted at seeing the missionary come to visit her at her bedside. He went to the window and saw on the sill a broken teapot, and in that was a Strawberry plant. The missionary rejoiced at seeing the plant growing in the broken teapot, and by way of comforting her he remarked to her that it was thriving well and that she would have some fruit. "Oh!" said she, "it is not for the sake of the fruit I cultivated it, but unable as I am to support a living thing near me"—for she had not even a cat or dog in the room with her—"I would like to have some living thing, for that living thing draws its life from the Creator, and I think when I have God near me who made this living plant I am safe."

He had never yet discovered among the annals of crime, through all his experience as a magistrate, the man who was fond of flowers being convicted of a crime. They had different kinds of flowers—they had the Orange which many liked, and which was a beautiful flower, and for his (Chairman's) part, he liked the "shillelagh" with its "Shamrock so green" (cheers and laughter). But upon that neutral ground they all could assemble together. He would have his flower, but there was no hostile feeling intended; and each and every one should have the flower he liked best. It was a good character for a man when he was fond of cultivating his flowers, for it showed that he had a taste for, and was fond of them. He should tell them that in all parts of the world, and especially in Ireland, there were societies of every kind. There were farming societies, racing societies, they had boat societies, and while mentioning that he wished them all on board the "Devenish" some time or other (laughter). There were societies for breeding dogs, for cats, and for donkeys (more laughter), and for everything that could be mentioned; and why should they not endeavour to raise the poor man; add more to his means of comfort, of intelligence and knowledge? If that were done they might depend on it that they would be humanising the lower classes of society more than they have been, and instead of men wasting their time after great evils, they would all cherish flowers because they were cultivated by them, for God had blessed the land with them. The world at first was a garden, for God had put man, after he had created him, into a garden, and told him to keep it; and after man's fall God desired him to go and till the earth, after he had driven him out of the garden he had forfeited by his sin. All who cultivated the ground, who propagated flowers, and made them the ornament of their dwellings, deserved the highest praise, and were worthy of every encouragement. He would call upon all those resident in the parish to support the Society. If they did so they would soon find that whatever influence he possessed he would be delighted to afford them. He looked upon it as one of the most agreeable duties of the clergyman, not only to preach, not only to have religious worship in God's house, but to do everything that would tend to civilise and elevate mankind. To the poor man in his cabin go, and tell him that God never intended him to live in cheerless misery. Let him have his garden to cultivate his flowers, and he would soon become a

happy man. Flowers required a great amount of industry in their cultivation, but without industry and contentment, it was impossible the country could be what it ought to be. Let a man have a large or a small garden, if he cultivated it, it proved that he was a neat person; and he who had a nice garden would be sure not to allow the Dockleaf or the Ragweed to flourish in it. He liked the man who cultivated his garden, and he only hoped that that show was the beginning of a brighter era to many of those who knew not the pleasure enjoyed in the cultivation of flowers, but who would yet have a neat garden to exhibit as the result of their taste, their labour, and their industry. It would afford contentment and pleasure, for it would place all on the road to reach that happy goal.

The choir of Kilskeery church, led by Miss Porter, sang the anthem, "Thine O Lord is the greatness," with sweetness and effect. Next followed an exquisite chorus, "The Apple Tree," which was most creditably performed, and then "God save the Queen."

A vote of thanks to the Ladies' Committee, and another to Mr. Fitzsimons for his exertions, were next severally proposed and carried with acclamation, and the proceedings terminated.

In the evening refreshments were partaken of by the exhibitors and the choir in the school-room, which was tastefully decorated for the occasion, after which the prizes awarded at the show were distributed to the successful competitors.

BATTERSEA PARK.

GARDENERS residing in distant parts of the country who only visit London once every three or four years, must be struck with the altered condition of the public parks, more especially if their visit should be in the gay period of the flowering season; but even in mid-winter they will perceive beds of evergreen shrubs embellishing plots which formerly deciduous trees or bushes failed to render cheerful before spring. Certainly the difficulty in obtaining a good display in the more central squares, and those portions of the parks which border densely-crowded localities, is such as will prevent their competing with more favoured spots; but the perseverance, skill, and management displayed in ministering to the taste of the public for flowers is worthy of all praise; and that those for whom such things are prepared duly appreciate them may be learned from the fact that though so many thousands daily throng those places of health and instruction, comparatively little damage is done to the plants, or other objects they so freely enjoy.

Of the open spaces devoted to public use, amusement, and recreation, around the great metropolis, undoubtedly the most useful are those situated in the most central positions. Unfortunately such positions are not the best adapted for vegetation: hence the difficulty in keeping them ornamental. The suburbs, however, afford a greater display. I must confess being agreeably surprised on a recent visit to the Victoria and Battersea Parks to find flower gardening so well and so extensively carried out. I mention both as being at opposite sides of London, the former exhibiting in the formation of its grounds an amount of taste which was rarely apparent in the early works of the kind in this country; while the latter, from the persevering efforts made to bring novelties before the thinking public, is also worthy of the highest praise, and a visit to Battersea Park will well repay the gardener who lives within a convenient distance of London.

Battersea Park, as it is called, occupies a large extent of flat, level land, lying on the south side of the Thames, the river forming its northern boundary; and to accommodate that numerous class of travellers who avail themselves of water transit, there is a landing-stage communicating with the garden, by which hundreds of visitors pass in from the steamboats every day. The natural flatness is in a great measure broken where necessary, by the various belts and clumps being, in most places, judiciously planted on mounds or knolls evidently of artificial formation, but approximating more closely to nature than is often the case elsewhere. The ground is divided into compartments by drives or public thoroughfares for vehicles, the sides at such places being

fenced in by suitable iron railing. Other walks cross the ground in different directions to which carriages are not admitted; and yet with all these sub-divisions, and the broad and irregular belts of shrubs and trees which in many places take off a wide margin from them, there are, nevertheless, several plots of unbroken ground of apparently six or eight acres each, appropriated as cricket ground; and excepting that at the time I saw it, the turf was, like that of every other place, suffering from the dry weather, it would be difficult to suggest a more suitable spot, while the rising boundaries of shrubs and trees gave the snug, rural appearance of a country district. I may add that the belts which generally fringe the drives are not formal and regular, but broken and diversified in many ways, as is likewise the ground, a bend inwards of the mass of shrubbery in one place being followed in another by a complete break through, so that the traveller on the public thoroughfare may be able to obtain a peep of the interior. Now and then beds of flowers are introduced with good effect, the wavy outline of the ground rising into a gentle swell, its summit crowned with plants suitable to the place; in other parts a piece of water is fringed with plants suitable to the position, while ever and anon the gay colours of the bedding plants present themselves in the distance, inviting a more close acquaintance. Often unexpectedly the visitor comes upon beds of plants not usually met with, as Cannas, Hedychiums, and plants remarkable for their foliage.

A semicircular plot of considerable extent near the centre of the north side was divided into a number of beds that were most tastefully filled with bedding plants of the most showy kinds, and all well grown. A series of wedge-shaped beds forming a sort of fan, having a circle from which each bed radiated was most beautifully arranged; perhaps the most telling bed being Coleus Verschaffeltii and Centaurea candidissima, the latter forming the margin, and one or two (I forget which), broad lines of it running down the middle, the Coleus being in the intermediate space. Both plants were as richly coloured as could be desired by the most ardent admirer of good cultivation. The other beds were also good, being filled with Geraniums, Lobelias, Verbenas, and the various classes of plants usually met with in such places; but what surprised most visitors who thought themselves entitled to give a good opinion on such matters, was the great number of plants which elsewhere have the character of being scarce and costly. I fully believe I am speaking within the mark, when I say that fully a thousand plants of Geranium Mrs. Pollock were planted out, and many others equally rare elsewhere seemed to be in abundance here. The episodal flower gardens to be met with at the various points, all differing in character from each other, had each their separate charms, and as regards good arrangement, good keeping, and general efficiency, were all alike good. A rosarium was formed at what I believe to be the south-eastern side of the Park, the beds of Roses being embellished, as is usual at this season, with China Aster and similar plants, and from the appearance of the permanent occupants, had evidently been gay at an earlier period of the season.

We now come to what is by far the most important feature of the place, in fact one which astonishes the most practical and enterprising amongst us, for there are objects (apparently by our previous acquaintance with them), fresh from the tropics, or from some climate corresponding thereto. The sub-tropical garden as it is called, forms a compartment near the south side of the Park. A sort of broken ridge, from 4 to 10 feet high, forms the outer boundary of a plot which may be termed nearly circular. This outer ridge is agreeably broken by side spurs giving it a pleasing and natural appearance; and these elevations, being planted with shrubs and trees of a thriving kind, form an excellent shelter to the inside, which is still further sheltered from cold winds, or it may be parching sun, by eminences of a like character within the outer barrier.

These internal mounds or eminences being also clothed with suitable trees and shrubs, and so arranged as to form some well-sheltered vallies or corners, the place is admirably adapted for the purpose to which it is put—that of growing some of the many stove plants we have so long regarded as impossible to keep out of doors. All these vallies have the shelter of the higher ground and surrounding

vegetation, the plots being at the same time sufficiently high to insure good drainage, and the many plants turned out upon them are essential features. Plants requiring shade had their allotted place; probably a Weeping Willow hung over a tropical Fern, or a Beech might do the same kind turn to a Palm, for even this section of the vegetable kingdom had its representatives at Battersea; while in the more open spaces beds of plants remarkable for the singularity of their foliage might be seen at some distance from the general path, care being taken to introduce them so that the best general effect might be produced. Unfortunately my visit was a hurried one, and I had not time to notice more than a very few of the objects to be seen; but I may observe that as well as beds of the different plants grouped together, there were many single plants turned out on the turf, which so far as their appearance was concerned might have been there for years.

Entering the enclosure on the north side, the first plant I met with was a stranger to me, *Griselinia macrophylla*, a plant of which the appearance and growth resemble *Ficus elastica*, and widely different from *F. littoralis*, a densely-foliaged evergreen shrub not half so much grown as it ought to be, and which with me is as hardy as the common Laurel. Farther on a handsome tree Fern spreads its umbrageous fronds underneath a tree more common to the climate; but apart from such shelter might be seen a bed of *Dracæna terminalis* luxuriating in all the richness of colouring which makes it so great a favourite with the visitors of our hot-houses. In like manner plants of *Brugmansia* stood out as sentinels here and there on the turf, with now and then a *Ficus elastica* of goodly proportions in the same position; in one or two cases a bed of the latter formed an interesting feature, but not more so than beds of the *Croton picta*, yet the latter, or, rather, a newer and improved species of this fine old favourite, was to be met with by the score planted out, and, to all appearances, enjoying the climate of Battersea instead of Batavia. There was no scorching, blistering, or withering; all seemed in perfect health and condition. In another place fine plants of *Marcantia zebrina* spread their finely-formed leaves over plain English turf, or a few would be grouped together to form a bed; while further in the distance would be seen the commanding foliage of the various *Cannas*, some being of an almost bronze hue, while others were of a delicate green. *Hedychium* also formed other groups of a somewhat similar kind; while *Wigandia* and *Palma Christi* waved their noble foliage in luxuriant profusion in the distance, not but that a nearer acquaintance would be now and then made by a specimen advanced towards the low iron fence, which very properly shut out the throngs of visitors who occupy the walks. There are also some species of *Arundo* not commonly met with.

As respects Ornamental Grasses, there was a most beautiful white-edged kind, forming an edging to a small bed. An older species adjoining it (*Dactylis glomerata*), resembles it much in habit, but is much less white in colouring. *Stipa pennata*, or another *Stipa* of similar growth, is also brought into effective use; while ever and anon the eye would fall on a mass of *Centaurea candidissima* in quantity sufficient to make many of us envy the store from which it came. Even a *Centaurea* more rare than this (*C. argentea*), was to be met with in hundreds, and though it is less really white than the other one, its finely-cut leaves give it a rich appearance. A kidney-shaped bed of *Coleus Verschaffeltii* edged with *Centaurea argentea*, had as rich an appearance as could well be conceived; though not more so than a circular bed of the same plant with an edging of *Centaurea candidissima*. Many other plants not at all plentiful even in hothouses were here planted out by the score; but I do not recollect seeing any *Begonias* in a flourishing condition; I might, however, have overlooked them. *Caladiums* there were, and Ferns of various stove-kinds, including *Gymnogramma chrysophylla*, and sundry others, which, in my hurried visit and the expectation of repeating it, I did not notice. When such veterans in plant-growing as Mr. Veitch, of the Exotic Nursery, Chelsea, express themselves astonished at the many valuable plants met with out of doors, I may with confidence strongly advise every gardener visiting London to go and see for himself; and if the same plants met his eye as occupied the sub-tropical garden in the middle of

August, he cannot be otherwise than astonished, and return pondering on what he has seen, and the field for enterprise which has been opened up.—J. ROBSON.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

URCEOLINA PENDULA (Drooping Urceolina). *Nat. ord.*, Amaryllidaceæ. *Linn.*, *Hexandria Monogynia*.—Imported by Messrs. Veitch, of King's Road, Chelsea, through their collector Mr. Pearce. Native of woods on the Andes at Pozuzo. Flowers yellow, green-tipped, and white-edged, urn-shaped, drooping, in an umbel; each on a green tube so narrow as to resemble a pedicel. Bloomed in June.—(*Botanical Mag.*, t. 5464.)

MACLEANIA PULCHRA (Showy Macleania). *Nat. ord.*, Vacci-niaceæ. *Linn.*, *Decandria Monogynia*.—A handsome glabrous shrub. Native of New Grenada. Flowers scarlet, with yellow limb.—(*Ibid.*, t. 5465.)

CYPRIPEDIUM CARICINUM (Sedge-like Lady's Slipper). *Nat. ord.*, Orchidaceæ. *Linn.*, *Gynandria Diandria*.—Native of Peru. Introduced by Messrs. Veitch through their collector Mr. Pearce. Requires a stove; blooms in May. Flowers pale green, white-margined, tipped partially with purplish brown.—(*Ibid.*, t. 5466.)

ERANTHEMUM COOPERI (Sir Daniel Cooper's Eranthemum). *Nat. ord.*, Acanthaceæ. *Linn.*, *Diandria Monogynia*.—Raised by Messrs. Veitch from seed received by Sir D. Cooper from New Caledonia. Bloomed in a warm greenhouse during June. Flowers white, with middle one of the lower limbs dotted in purple lines.—(*Ibid.*, t. 5467.)

GENETHYLLIS FIMBEIATA (Thyme-leaved Genethyllis). *Nat. ord.*, Myrtaceæ. *Linn.*, *Icosandria Monogynia*.—Native of south-west Australia. Introduced to our greenhouses by Messrs. Veitch. A lovely shrub; but its crimson involucral scales are its ornaments, the flowers within them being small and insignificant.—(*Ibid.*, t. 5468.)

PELARGONIUM.—*United Italy*. Exhibited by Messrs. Henderson & Son, Wellington Road Nursery. It is one of the tricoloured-leaved varieties. Margin of leaves creamy white; next a broad zone of crimson pink; next a bronzy dark shade; and centre green. Flower small, scarlet. It is a good dwarf pot plant.—(*Floral Mag.*, pl. 209.)

TEA ROSE.—*Alba rosea*. Creamy white; inner petals rosily tinged.—(*Ibid.*, pl. 210.)

FANCY PANSIES.—John McNab, ground pale sulphur; broad border of plum, margined with white. Mrs. Doimbrain, pale yellow; eye very large, and spot of deep purple, radiated; centre deep orange. Mrs. R. Dean, pure white, with eye and spot violet purple, shading to a paler hue. Mrs. Scott, cream-coloured ground; violet purple margin, shading paler inwards; eye and spot of same colour; centre deep orange. All sent out by Messrs. Downie & Co.—(*Ibid.*, pl. 211.)

PYRETHRUMS.—Annie Holborn, very double, white; centre delicate lilac. *Fulgens plenissima*, large, dark crimson. *Nemesis*, large, rosily red; centre lighter.—(*Ibid.*, pl. 212.)

CLEMATIS JACKMANNI.—This very beautiful hardy climber originated at the Woking nursery of Messrs. G. Jackman and Son, and is, we believe, due to a happy idea which crossed the mind of Mr. G. Jackman, jun., which was to the effect that some of the blood of *C. lanuginosa*, thrown into the large-flowered hardy species and varieties of this genus, would result in the production of something good. The result has fully justified Mr. Jackman's anticipations; for the seed thus obtained has yielded a large batch of magnificent seedlings, with flowers of all shades of purple, varying towards lilac on the one hand, and a reddish plum or maroon colour on the other. One of the most marked of the whole series, so far as they have yet been proved, is *C. Jackmanni*.

"The mother parent of this batch of seedlings was *C. lanuginosa*. This was crossed with *C. viticella* *Hendersoni* and *C. viticella* *atropurpurea*, from which latter, no doubt, has been derived a rich reddish plum tint, which is found in many of the seedlings, and of which *C. rubro-violacea* is a beautiful example, scarcely, if at all, inferior to, and perfectly distinct from, *C. Jackmanni*. The seedlings flowered for the first time in 1862, and both the varieties we have mentioned, selected from amongst them, were shown in August, 1863, at a meeting of the Floral Committee, and

were both awarded first-class certificates. The seedlings are all remarkable for a lustrous richness of colour, which greatly enhances their beauty.

"*C. Jackmanni* has ovate leaflets of moderate size, and slightly hairy. The flowers, which open flat, are 4 or sometimes 5 inches across, and have a variable number of from four to six sepals, of a roundish-obovate form, terminating in a little point, downy behind, and on the face of an intense violet purple, the colour being remarkable for its rich velvet-like appearance. The back of the sepals is marked by three ribs, which show like three slight furrows in front, the rest of the surface being veiny and somewhat rugose.

"*C. rubro-violacea*, to which allusion has been made, has the flowers of a rich reddish-tinted violet, and, when fresh opened, is almost maroon-coloured, and very remarkable for its velvety surface.

"Being perfectly hardy, of free habit, and flowering abundantly during the summer months, these new hybrid Clematises of the Jackmans are well worth a place wherever hardy-flowering climbers are cared for. We believe the two sorts to which we have alluded are to be sent out during the present autumn."—(*Florist and Pomologist*, iii., p. 193.)

HEDGE TRIMMER.

A VERY slight alteration makes a great improvement in many of our garden implements, and the above is an example. The hedge trimmer is usually fixed upon a straight handle, but the above sketch illustrates such a hook or scythe as is used by an experienced hedge-grower. He procures a stick with a natural crook like the above—the main handle being about 6 feet long, and slightly curved and turning so as to form as nearly as may be a right angle—to which short end, say 6 inches long, a short strong bush-scythe is attached; this affords a strong substantial implement, and the bend of the handle enables the operator to bring the whole length of the blade against the sprigs of the hedge, and yet avoid being scratched. The hook is used by striking upwards and laterally.—(*Prairie Farmer*.)

BEDDING GERANIUMS.

(Concluded from page 194.)

WHEN there is not convenience to winter Geraniums in houses without making these unsightly by a number of ugly boxes filled with the old stumps, the plants are denuded of their leaves and the old parts of the wood, leaving most of the roots, and placed in dry sand in a cellar, or in any cool place from which frost is excluded, and all the better if a tolerably equable temperature be maintained. In this position they remain until March, when they are either potted or placed in boxes in moderately rich soil, and removed to a frame with a gentle heat, a greenhouse, or any house of a similar temperature, water being given them as they commence growing; and when they have fairly pushed, any straggling or irregular growths are shortened. The plants are gradually hardened off, so that they may bear exposure by the middle of May, when they are placed under a wall or hedge prior to their being planted out. Such plants, though very unpromising, make very fine beds by August.

Another practice is to take up the plants on the approach of frost, and hang them up root upwards in a cellar or other place secure from frost, pulling off all the large succulent leaves, which if left damp-off and frequently communicate the disease to the stems. Such plants are potted in the following March, and placed in a greenhouse or frame with or without a gentle heat, and not unfrequently in narrow boxes 6 or 8 inches wide, and the length of a window. They are carefully watered, and after some time they commence growing, and are finally planted out in the open garden.

These plants recover wonderfully after they are turned out, and not unfrequently by August are equal to others grown under more favourable circumstances.

It is astonishing what a desire to have anything and perseverance will accomplish, and of this the following is an instance. In the village of A— was a cobbler noted for his Celery-growing, who had a desire to have a bed of Geraniums in front of his shop. Some gardening friend gave him a cutting of that strong-growing scarlet Geranium, common enough at one time, but now rarely seen—the Royal George. This variety would cover the back wall of a greenhouse in a short time, and a single truss of bloom would make half of a modern nosegay. The cutting was placed in some mould (the remains of a heap of wood), in an old teapot the spout of which had been broken off. Well, it struck root, grew rapidly, and was attended to by the cobbler and his wife like an only child. It had a place in the window that it might receive the morning sun, and when winter came it was brought into the warm kitchen to be out of the reach of frost. It will bloom, perhaps, thought the cobbler, when it had reached the top of the window, and this without so much as a branch all the way, being like a walking-stick with a few leaves on it. By-and-by it was planted outside, and it grew like a tree, and bloomed to the satisfaction of the cobbler, who prided himself on the probability of having as fine a bed of Geraniums next year as the squire over the way. How to accomplish this was the question. To preserve the plant during the winter he planted it in a tub which he made, but it died. The gardener was again appealed to, and this time the cobbler received a cutting of that old but not yet superseded Scarlet Geranium, Tom Thumb. It grew, and in a few years the old cobbler had a bed of Scarlet Geraniums, which were admired by many; and the squire, whose gardener had given him the cuttings in the first instance, admired them so much that the cobbler was much elated, and considered himself equal to the rector's boasting man, who was so clever in his management of Geraniums. Owing to some little altercation between them, a wager was made as to who would have the better bed of Geraniums in the following year. The cobbler had every box and pot that he could muster crammed with cuttings, and these he succeeded in wintering with the same attention as he had bestowed on the Royal George. However well they were wintered, he put his pots of cuttings outside in anticipation of a shower of rain, and left his home for the day. A hailstorm occurred in his absence, and the plants were destroyed. To purchase plants would lose the cobbler the day, so he was almost inclined to acknowledge himself defeated. It happened that he had pitted his Potato crop in the place where the bed of Geraniums had been in the previous summer, and the Geranium stems had been buried beneath the Potatoes, for on removing these in April, the old Geranium stumps had shoots upon them an inch long, and white like everything grown in the dark. The squire's gardener over the way volunteered his aid, and it resulted in the cobbler placing some sticks over the Geranium stumps, and covering them at night with straw, but taking it off during the day. In conclusion, the cobbler defeated the rector's man, and won the wager, and this so chagrined the loser that he gave notice to leave, and the cobbler was appointed in his stead. He is now a hale old man, pensioned by the same worthy rector at his death; and if you come into conversation with him about Geraniums, he will say, "There is no better way to keep them over the winter than to pit them like Potatoes." We may learn from this that there are many different modes of wintering Geraniums, and to describe them all would be tedious.

In wintering the Variegated, and small or weak-growing Scarlets, it is necessary to pot them or place them in boxes, without taking off more than the bruised extremities of the roots, and to thin the heads if large and unwieldy, without reducing them much, or shortening the branches. Some kinds, as Golden Chain, will not require the head to be reduced at all, it being desirable to obtain as large plants as possible. Such as Bijou, Manglesii, Flower of the Day, and others, should not be cut-in too much, though they will bear more autumn-cutting than many sorts. The shoots left ought not to be shortened, and no leaves should be taken off except such as are old and useless.

Whether potted or placed in boxes the plants should not be kept in cellars, nor in any dark place, but in a light, airy situation in the greenhouse, water being sparingly applied, and only when necessary, and all decayed leaves must be removed as they present themselves.

In March the plants should be potted, if planted in boxes in the autumn, placed in a higher temperature, afforded moisture, and in a week or ten days cut-in closely. If no suitable house be at command, they must be potted as above, but not be cut-in so closely, as they will not push so freely. Except in this the treatment of the Variegated and smaller kinds of Scarlets does not differ much from that recommended for Scarlets generally; they require, however, rather more heat, less pruning, and greater care as regards watering, and hardening-off in the spring prior to planting out. The greatest enemy of Geraniums in winter is damp, and a close vitiated atmosphere. A high temperature is also injurious, as it causes growth at a time when it cannot be properly consolidated. Hence weak, lanky growths which never become strong are the result.—G. ABBEY.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Weeds this season may, with half the usual trouble, have been quite eradicated. Potatoes and other crops are coming off early, so that the process of manuring and trenching may be prosecuted at every favourable opportunity. We would never recommend, if it can possibly be avoided, to dig the ground intended for general cropping simply one spit deep. Even if the soil be shallow and the subsoil ungenial we would remove the top and well break up the bottom of the trenches; these operations pay for a little extra trouble, and now is the time to commence them. Cabbages, let all the remaining summer sorts of a solid character be cut over in order to obtain a good succession of sprouts. See that the ground is in readiness for transplanting the winter Cabbages. Remove all dead and decaying leaves from the Brassica tribe in general to some ground under the process of trenching, and keep the earth well stirred about the plants. Carrots, sow Early Horn in a sheltered place to stand the winter. Cauliflower, to be looked over frequently, turning down a few leaves over the hearts, for they are readily spoiled by frost. Celery, that which is not earthened-up must have the soil stirred about it with a fork, and frequent applications of liquid manure. Chilies, these and Gherkins, Onions, and other vegetables used for pickling, should be gathered for the purpose as they come in. French Beans, provision should be made for protecting them from frost, should this occur. Lettuce, let a lot of Brown Dutch or Bath Cos be planted where they can be protected by frames for spring use. Tomatoes, train, stop, and thin the laterals, but avoid stripping off too many leaves. The cultivation of Watercress should not be omitted in the series of salads. Bottles with their necks broken off and plunged in the ground, saucers, and any other shallow vessels to hold water will do to grow it in. A yard square will give a useful supply; and all the attention that will be required will be to fill up any deficiencies of water caused by evaporation. A damp shady border is not unsuitable; but wherever the advantage of a small stream is possessed preference should be given to it. If the trimmings of the bunches are thrown in throughout the season a regular supply of fresh young cress may be obtained.

FLOWER GARDEN.

As cold nights may soon be expected, scarce plants which it may be desirable to secure before they are injured should be taken up and potted at once, or carefully covered where there is the least cause to suspect injury. See to securing a good stock of cuttings of variegated Geraniums before the plants are injured by frost; for although these root more freely in spring than at present, such varieties as Golden Chain and Mountain of Light grow so slowly that spring-struck cuttings make but very poor plants by turning-out time. Hollyhocks and Dahlias will now require occasional looking after to secure them against the effects of high winds, which may now be expected. Unless seed is wanted, cut away decayed flowers and useless shoots. Herbaceous plants will likewise require the stalks of decayed

flowers removed, and such as are still in bloom carefully tied up. Asters, some Phloxes, &c., will now be making a fine show, and should have corresponding care bestowed on them. Let the borders be cleaned and neatly raked over, filling vacant places with spare Chrysanthemums, spring-struck Pansies, or spring-flowering bulbs. Though we advocate the autumnal planting of evergreen and deciduous shrubs, we would not recommend their removal at an earlier period this month as long as the late very dry weather continued; but the happy change in the weather will now enable those to proceed vigorously in their operations who intend alterations or new arrangements in this department.

FRUIT GARDEN.

Look over wall trees, and cut off all foreright breastwood, or what are called "after-shoots." Strawberry plants in pots must not be allowed to get very dry, nor ought they to be drenched with too much water. General attention to gathering all sorts of out-door fruits as lately directed.

STOVE.

A certain and gradual reduction of temperature corresponding to the deficiency of external heat should be commenced, the plants will thus be prepared to withstand the prolonged gloom of the winter season. All stove plants, which have been removed to the conservatory or other houses, should now be brought back to their permanent stations without delay, both for their own sakes and for the sake of the general arrangement in other structures. Give most liberal ventilation, not forgetting, however, to accompany it with much warmth; for the hardening of growths is not carried on by means of chilling draughts, but by high temperature accompanied by a free perspiration from the leaves of the plants. Much attention must be given to watering under the above circumstances.

GREENHOUSE AND CONSERVATORY.

Unremitting attention must be given at this period to the housing of tender plants until the whole stock is secured. The Persian and other Cyclamens should be examined and repotted where necessary. The Lachenalia family should now be brought forth and repotted; such on a greenhouse shelf will flower in February. Camellias, Chinese Azaleas, and some Acacias, will not be hurt for a week or two, if circumstances do not permit of their being housed immediately. Greenhouse and stove plants of an herbaceous character, after they have done blooming, should have some care in order to ripen the roots properly before they are stored away for the winter. To effect this with Achimenes, Gesneras, and Gloxinias, they should be placed in a spare house or pit near the glass, and only supplied with water to keep them from flagging. Amaryllis and the different varieties of Japan Lilies require the same treatment, the latter, however, being more hardy may be ripened off at the base of a south wall or cold pit. Admit air night and day to all descriptions of greenhouse plants. In many species the growth is not yet perfected. This may be assisted on sunny days by early closing for a couple of hours in the afternoon; but open the house again at six for the cool night temperature.

PITS AND FRAMES.

These should now be furnished with bulbs of the most approved varieties for forcing. Pinks in variety, Neapolitan and Russian Violets, and sturdy young plants of Wallflowers in variety. Mignonette to be thinned in due time, Intermediate Stocks pricked-out, one in a small pot, Cinerarias repotted, and herbaceous Calceolarias parted and potted, and plunged in cinder ashes in a cold frame near the glass.—W. KEANE,

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

THOUGH we have as yet no water for vegetables, the mild showers have moistened the surface of the earth, and enabled us to pick out Cabbages, Cauliflowers, Lettuces, Endive, &c., with but homeopathic doses of moisture at the roots. The air is now so moist that plants that have had a fair start will not suffer much. Could we have planted out lots of winter stuff by the middle of June, the plants would not have suffered from the drought; but our limited space was then as thickly cropped as could be. The slight showers and what little sewage we could give, is now taking the

slaty appearance from our vegetables. Cauliflower with our mulching never was better, and succession crops are now coming in between Peas, which we have left standing long after they were withered, that they might give shade to the Cauliflower. No time should now be lost in taking up Potatoes in the southern districts. The less time they remain in the ground after the haulm decays the better they will keep.

It is a good plan to sow *Lettuces* rather thickly now on hard ground, that has merely been slightly hoed and raked, either at the bottom of a wall, or fence, or on the open ground in beds, with shallow trenches at each side, to take off the winter's moisture. The harder and the poorer the ground, provided there is enough loose soil for the plants vegetating, the better will they stand the winter, and the more stubby will they be in spring.

Now is also a good time for pricking out *Lettuces*, some 2 or 3 inches high, in rich soil about 3 inches apart, to be lifted in a fortnight or three weeks with a trowel, and placed in pits or frames 8 or 9 inches apart for the winter. Such pits and frames are none the worse of having some dry litter placed at the bottom before the earth is put on for the *Lettuces*. This answers better than an old hotbed, the dry litter and plenty of air being a good preservative against damp and mildew. Snow's Matchless, a hardy green *Lettuce*, and Brown Cos, are good as Cos *Lettuces*, and Hardy Hammersmith and Victoria are capital Cabbage *Lettuces* for that purpose. Such plants may be expected to keep up a regular supply until the middle of March, when those at the bottom of the fences will come in. Two things are essential to success: first, that the plants be pretty well established before winter; and, secondly, that the surface soil be pretty dry by the first week in November. Young plants may be put in the pits and frames at once, if the latter are at liberty. A third essential to success, is not placing the plants thicker than mentioned above, if they have to grow and come in in succession. We have filled a frame at the commencement of winter with good plants lifted carefully then, and though they did for current use, they never thrived like those that were planted out young in their winter quarters. In some places *Lettuces* are as much run after in winter as *Potatoes*, and in such circumstances some care must be had to secure them. Where it is understood that they will not be wanted, of course all the trouble may be saved, and the room be devoted to other purposes.

We have now removed most of the branches that shaded our Celery, and they and a little mulching we hope have done much to make amends for no watering for nearly two months in the hot burning weather. The season has convinced us more if possible than heretofore, that in such periods of dryness much may be done by deep stirring, surface-moving, mulching, and frequently turning the mulching, if at all thick. What has suffered most with us are autumn Peas. What used to be fine in September are pretty well a wreck.

Bindweed-killing.—“No GAMMON,” writes us to say, “That he has never known the weed destroyed by hoeing as we stated last week; that he does not believe that it can be so destroyed; that it is very wrong of us to hold out such vain inducements; asks if we have thoroughly eradicated it, &c.” To the last we reply, No! just because in the busy season it is apt to obtain the ascendancy before we notice it or get to it; but we have no doubt the hoe will master the enemy if the attack is made in time, and repeated in time. We cannot help any man's belief or unbelief, that is a matter that rests with himself, and if “even convinced against his will,” strong-minded people will often pretend to be “of the same opinion still.” Acting in good faith, we may derive instructions from the doings of men, and yet not be at liberty to mention their names publicly. There might be no great liberty taken in doing so in the present case, though it is best to be sure; but if “No GAMMON,” will give us his name and address in confidence, we will in the same confidence give him the address of the gardener and the place referred to, and then he can satisfy himself whether we deal in fancies or in facts.

Mushroom-growing.—“UNFORTUNATE” would be much obliged if we would give a little more elucidation of the expression at page 197, “Whatever the materials are, it is our part to vary our treatment according as we find them.”

Most willingly, though it must be in a few words. We have several times stated that horse-droppings, with a little litter, are the best material; but we have used for the bulk of our beds almost anything that would yield a mild heat from decomposition. One of the best beds we had last season was made of three parts of stubble and one of long litter, thrown together, and wetted a little to make it heat, and as soon as it smoked a little it was put as firmly as possible into the bed 16 inches deep, and covered over with a couple of inches of droppings. This material we knew would heat and cake itself pretty dry, and thus lose heat; but by making some holes about 2 feet apart in the bed with a round stick, and pouring in some water, we set the bed working afresh, and thus the crops were prolonged. If the bed had been made of moister materials the plan would not have answered. Again, we have made the great bulk of our beds of fresh fallen tree leaves. They are apt to produce fungi of many sorts. To prevent this throw them into a heap to ferment violently, which will kill most of the fungi of all kinds, and then when trodden in a bed of moderate thickness they will long retain a mild regular heat. These, surfaced with 2 or 3 inches of droppings, will make a capital bed.

If common horse and cowdung, along with litter, is wrought and turned in a heap, so as to be fit for a Cucumber-bed, it will be in first-rate order for a Mushroom-bed. If that should be rather dry you could give a casing 1 inch thick of moist manure—horse or cowdung. If from the weather or other causes the material should be too wet, each piece of spawn should be wrapped in a handful of dry short litter. The fresher the materials are, provided there is no overheating, the greater the success. The state of the materials, as respects dryness, is also of importance. We have seen horse-droppings turned and dried, and turned again, in sheds, until all the virtue was driven out of them, and then beaten firmly into beds, which did little good, because they were made too dry, and kept too dry by means of a flue without a moist atmosphere. A little more moisture and freshness in the material, and a coating of moist material after the spawning, with a moist atmosphere, would have made all right. In winter, especially, it is sometimes difficult to obtain the material dry enough. It is best when it is about the dryness of soil we use for potting—that is, you may squeeze it in your hand, and it will retain all the traces of your fingers, but when you lay it down it will crumble into pieces. We have made beds with material so damp that one could squeeze the drops of moisture out of it. This is much too wet for the spawn to run in. It exhausts itself, or is quite destroyed. In such circumstances inserting the spawn into the handful of dry litter, and keeping it pretty close to the surface of the bed, was the safety valve. The spawn ran freely in the litter, and the damp surroundings proved a rich feeding ground. So much then as to materials and their condition, which is nearly of as much importance as temperature, but which was sufficiently alluded to in a late article.

FRUIT GARDEN.

Commenced clearing the lines of Strawberries, will surface-hoe or slightly fork, and then place litter and dung between the rows. Would have done so earlier but for the drought and the deficiency of mulching material. Gave a little more room to Strawberry plants in pots that the crowns might be better ripened. Have kept them growing chiefly with a little sewage water. They are mostly in 40-sized pots this season. The forced ones planted out have given little fruit this autumn owing to the dryness. Figs out of doors have thrown off a number of their fruit from dryness at the root, and we could not help ourselves. The orchard-houses which have borne amazingly, are pretty well emptied of their contents, with the exception of Figs in pots, Plums, Pears, &c., in pots, and late Peaches against the wall. Our chief objection to the pots is the water they require, and our scarcity made us resort to some rather questionable liquids. To Figs planted in the house we gave a good watering with sewage water, and kept the house closer for the second crop which is now coming in. Syringed the trees done bearing in orchard-house with clear soot and clear sulphur water. On a dull day shut up the Peach-house, put a fire to the boiler, and painted the pipes with sulphur, and when hot syringed the house well, as the red spider appeared from the dryness. For two months past we could do little syring-

ing. We resorted to it in the conservatory, because by that means, shading, and little air, much less water was required than would be needed for watering the plants. Gave water to Melons looking a little distressed, giving it chiefly to the roots without wetting the surface soil much, as the drier the surface now the better the flavour. Picked out any decaying berry from Grapes, and removed all the laterals from the early house, and about half from the late house, to admit a little more light. Gathered Plums, the last of Apricots, and a good many of the early Apples, and commenced with two parcels of Williams's Bon Chrétien Pear from the same tree. One tree may thus last six weeks, by taking the largest and ripest first. If all gathered together the fruit would be in good condition only a few days. The winds have rattled down much fruit prematurely, and if possible it should be gathered up, as if left it gives an appearance of carelessness. Apples we suspect will be very cheap this season, which will be a boon to our brethren in "cities pent." The ripeness of Apples and Pears is best known by the brown colour and firmness of the seeds.

ORNAMENTAL DEPARTMENT.

Our work here has chiefly been threefold. First, potting stove and greenhouse plants, and Primulas and Cinerarias, and taking Camellias, Azaleas, and hardwooded plants at all tender, under protection, or at least where they can be defended from heavy rains. Many ornamental plants of an annual character, as scores of fine Balsams in full bloom, Feathered Cockscombs, Browallias, we were forced to throw to the rubbish-heap, as we could not water them, and keeping them dry in houses or pits would have been no pleasing sight, and would most likely have furnished us with shoals of insects. Secondly, we drew the scythe over most of the pleasure ground to make all level, for there was little to cut, the mowing machine having enjoyed a sinecure this season, then clipped the edges and dressed the sides of beds, and rolled the grass, which is now becoming greenish, which improves the look of the flower-beds. The skiffs of showers and high winds have thrown off many of the Calceolaria flowers, but the shaded side of one pyramidal bed still looks massive—in fact the Calceolarias, though now far past their best, have stood the dryness much better than we expected they could do. Scarlet Geraniums are still very fine, though beginning to seed, and the dryness will prevent much succession. These unwatered beds in this parching season have led many people to suspect that there may be over-watering. Most of our amateur brethren declare that they will grow Geraniums in future, and have nothing more to do with Calceolarias; but what if next summer should be a dripping one? for then Calceolarias would be in their glory. It is amazing the interest taken in flower-beds by the possessors of small places. A manufacturer who has only had two seasons of practice, surprised us by knowing as much or more of the character of bedding-plants than we did. With such masters gardeners must not be idle or behind the times. Thirdly, though lothe to disfigure our beds, we are now taking off cuttings of Geraniums, &c., in earnest, but selecting pieces that will make as small a gap as possible. These are mostly placed in moveable wooden boxes, 2½ feet long, 9 inches wide, and 4 inches deep, one end being moveable. We use lumpy soil for the bottom, and finer fresh soil with a little sand for the top, and plant the cuttings from 1 to 1½ inch apart. The boxes are chiefly made from elm because we can obtain it easiest, made up at once from the saw, and then painted with lime wash inside and outside, as a preservative chiefly against fungi and moulds. It is a nice job for labourers to make them on a wet day. Gardeners in these times must be pretty well Jacks of all trades, and many labourers like such work rather than otherwise. In these days of the division of labour, it is generally best to have the right tradesman for his general work; but there are first-rate employers who would rightly object to bring a mechanic from a distance to do a trifling job. The men who go through the world most comfortably and often make themselves felt in it as a bettering influence, are men who do not stand upon trifles; argue about their rights, and descant about what they were engaged to do; but at a pinch do what is wanted, and without claiming extra merit or thanks for doing it. We once knew the greater portion of a glass house unroofed in a storm because the gardener

add nothing to stop up the gap of a few broken squares. He had given notice that a glazier was wanted and that was enough for him. He was not to turn glazier. No, not he! When the storm came on, he should have thought of the gap, though. Did his keeping strictly to his engagement advance his interests?—R. F.

COVENT GARDEN MARKET.—SEPTEMBER 10.

Heavy supplies both of home-grown and foreign fruit continue to arrive. Grapes, Figs, Peaches, Nectarines, Apples, and Pears are very plentiful; and Oranges have become more so in consequence of consignments of autumn fruit from abroad. Vegetables are abundant. Turnips, however, are very scarce. Of Potatoes there is a heavy supply, and the quality is good; the prices have therefore declined.

TRADE CATALOGUES RECEIVED.

Barr & Sugden, 12, King Street, Covent Garden, London.—Compendium of Illustrated Autumnal Floral Guide to Winter and Spring Gardening.

Hooper & Co., Central Avenue, Covent Garden.—Autumn Catalogue of Dutch, Cape, and other Flowering Bulbs.

B. J. Edwards, 222, Strand, London.—Autumn Catalogue of New and Choice Hyacinths and other Bulbs.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

MELONS NOT SETTING FRUIT (J. J.).—The vines are probably too close, and the pollen is not sufficiently aired to be fertile; the bed may lack water; the atmosphere may be moist through an insufficiency of air; and too little bottom, or too much top heat, with a close stagnant atmosphere, may be the cause of their turning yellow. The sort is a free setter. Without an outline of the treatment we are unable to speak definitely as to the cause.

FLOWER OF THE DAY GERANIUM CUTTINGS FAILING (J. A.).—The cuttings were probably potted in a rich compost, and were watered very freely, and the soil turned into a bog. We have many now struck in such a place; but they were not shaded except for an hour or two during the hottest sun, nor watered more than to keep the soil just moist.

MULE PINK (A. R.).—It is a curious example of morphology, and, like all others, seem to afford no clue to the cause.

STRAWBERRIES (*Ignoramus*).—For one early variety, plant Keens' Seedling; and for one late variety, the Elton.

FUNGS IN TAN (G. R.).—See an answer to a correspondent in last week's Number, page 198.

STOCKS (*Mouse*).—If it is Brompton Stocks you mean, it is now too late to sow them; but if you mean Intermediate Stocks sow them forthwith in a cold frame, and, when of sufficient size to handle, prick them off singly into small pots, or insert two or three in a 48-pot. Keep in a cold frame, with air daily in mild weather, protecting them with mats from severe frosts. Repot in spring if they are desired to bloom in pots, employing 24's for single plants and 18's for three's. A compost of good loam, with a little leaf mould added, suits them well. They should be sparingly supplied with water during the winter; but when brighter weather, and the plants are growing freely, water proportionately. They may be planted out-doors in the latter part of April where they are to bloom.

Moss ROSES OVER-LUXURIANT (J. K. D.).—Moss Roses are seldom over-luxuriant. Probably the soil is too rich and deep, and the wood is, therefore, not well ripened in the autumn. We should try moving them in the beginning of November, and see what effect that would have upon them; and keep them rather close pruned. Almost all hardy annuals would, we should think, do well with you, especially Candytufts, Larkspurs, Virginian Stocks, Venus's Looking-glass, Collomias, Clarkias, Lupines, Nasturtiums, Barbitonias, &c.; and in the greenhouse all the half-hardy annuals would do well. We shall have something to say about annuals in pots when the time shall arrive.

DRAIN FOR MELON-PIT.—EASTER BEURRÉ PEAR (A. Q.).—Unless the soil be spongy and wet a drain is not necessary; but if water drain into the pit from adjoining ground a drain should be provided to take such water away, or it will quench the fermentation of the dung. The Easter Beurré Pear is rather a shy bearer; but we have a fine crop this year on an espalier, and free from rust. We have it on a wall, and it does fairly, though not equal to many. As a rule, this year our trees on walls are not bearing so well as those on espaliers. Try the tree a little longer, root-pruning it if you think it is too vigorous, but mulching round it to the extent of the roots with half an inch of short manure if it be weak. It is a good Pear.

CAROLINA ALLSPICE PROPAGATING (Q. Q.).—1, It is best increased by layers, operating upon them in early spring (March). 2, Cuttings taken from anything out of character are liable to return to the original state. In taking cuttings of variegated Geraniums make choice of those parts showing the variety in character. It is seldom that entirely white leaves of Geraniums can be perpetuated by cuttings. 3, The Verbena has done very indifferently with us this season; the finer kinds have barely existed. We think this is due to the season; but, as this does not bear on your case, we know of nothing beyond what you have tried likely to get them to do better than to change the stock. We have found this successful when other remedies have failed. 4, Seeds of French Marigolds are usually perfected in England, and so are those of Tagetes pumila; but whether they are worth saving or not depends on the doubleness of the flowers of the former. The seed of badly-formed, badly-coloured, and semi-double flowers is not worth saving. Tagetes pumila is generally good, though occasionally it is not sufficiently ripened, and the seeds do not germinate.

MIMULUS CUPREUS AND TROPOEUM SPECIOSUM CULTURE (Hester).—*Mimulus cupreus* is a half-hardy perennial, and will not, therefore, do outside except in very favourable situations. Keep it in a pot in a cool part of the greenhouse, on a shelf near the glass, and water moderately during the winter, but do not dry it off. Sufficient water to keep it fresh is necessary. If you want stock take cuttings when the plant commences growing in the spring, these will root freely in a little heat; or you may take away rooted offsets now, or in the spring, and pot them at once. The *Tropaeolum speciosum* should be rather sparingly supplied with water in winter, but it must not be allowed to become dust dry, or it will suffer, if not perish. It does well in a compost of light turf loam two-thirds, leaf mould one-third, with a free admixture of silver sand. It winters safely in a greenhouse, but does not like damp. A light airy situation is the most suitable.

DRESSING A MEADOW ON HEAVY CLAY SOIL (*An Amateur*).—The best way to apply lime to such a soil is to mix it with four or five times its bulk of mould—say the turfy lumps from the sides of ditches, or any coarse soil that does not contain too many stones. This mixture ought, however, to be prepared a few months before laying it on; but lime quickly destroys vegetation, and assimilates itself with the soil with which it is mixed. A good coating of a mixture of this kind—say twenty or twenty-five loads to the acre—laid on in November, and brushed in with a thorn harrow in March, would be better than the blood manure; but, as it may be too late to prepare this mixture, we would advise you to lay on rough stable-manure as soon as you like, allowing the rain to wash in its nutritive matters during the winter, and in March rake off with a hay rake all rough strawy matter, and apply the dressing of blood manure. The latter ought to be given just before rain, if it can be managed so.

GLADIOLUS BULBS TAKING UP (*Pond-dhu*).—In general these are better taken up when properly ripened. In a dry sandy soil they may be left in the ground, as we have done with tolerable success; but in that which is of a damp or clayey nature they are so liable to decay, or fall a prey to slugs or other enemies, that it is better to take them up.

PETUNIA, PHLOX DRUMMONDI, AND SAPONARIA GROWING TOO LARGE (*Idem*).—It is difficult to keep these to the dimensions of Tom Thumbs, Lobelia speciosa, &c. Petunias may, however, be cut so as to be kept pretty low; but Phlox Drummondii will show very little flower unless allowed free growth; and the Saponaria can only be rendered dwarf by poor soil. If, however, you are anxious to have beds of uniform height, you had better only use Verbenas, dwarf Calceolarias, Geraniums of the various kinds, Lobelias, Cerastiums, and other plants which either grow about the same in height, or allow of being cut to that standard, and plant the larger and more uncertain kinds in outside beds or borders of a mixed character. Saponaria, however, is generally dwarf and compact enough, and we should have thought that the present dry summer would have kept it more so. Trimming this cannot well be effected. Thinning the plants, however, early in the season, may do good.

SEEDLING RHODODENDRONS (*D. Dobson*).—It is now time the plants were ceasing their growth. Better, therefore, gradually harden them off by more air, and withhold water to a certain degree. As the plants are so small, we would not prick them out until March, keeping the seed-pan or boxes in some cool place, secure from frost and damp. The latter is more especially fatal to the kinds partaking of the Sikkim breed, whose rough leaves seem to invite more moisture than the plants can endure in our damp winter climate.

VINE-BORDER RENOVATING (*T. W. U. R.*).—If your Vines be in good condition, we would not advise you to meddle with them; but, if becoming bad, we would recommend their being entirely taken up, and the border remade, as advised by Messrs. Fish and Thomson in some of their papers on the subject. If, however, a sort of half measure be advisable, we would say examine the points of the roots, and, if the ground be bad, remove it, and replace with a more suitable compost. We have known plenty of Vine-borders not wider than 10 feet, and yet do well; but if the roots seem disposed to travel farther, then by all means allow them. Of late years an open porous soil is thought the best for the Vine—one that will allow quantities of liquid manure being supplied without creating sourness. Lime in some way is an essential ingredient in the compost, but the kind called magnesian lime is improper. We have seen good results from using carbonate of lime, sea shells in liberal quantities, old mortar rubbish, stone shatter, and many other things, avoiding too much manure, which, after a time, seems to sicken the Vine, and it rarely succeeds well. If you are in that state we should say, Take them up as soon as ever the wood is ripe, carefully preserve all roots, plant these near the surface in the new border, and success will be certain. We have even known a tolerably good crop in the first year of the change; but this is not always to be expected if the Vines have been bad before. Partially lifting them may do good if they are not so far gone, and, the roots being enticed into a new medium, great improvement may be expected.

LAUREL CUTTINGS (*An Old Subscriber*).—Well-ripened shoots of the current year, with just a little heel of the old wood at their base, and about a foot long, may be put in by the end of September, or sooner, if the ground be moist; and, if buried more than half their length in the ground, they will nearly all grow. Trimming off the leaves that would be buried underground should be done, but a little branchiness of top is of no consequence. It is a lot we put in last year in this way, we find several of them have grown sufficiently to be transplanted in the present autumn, and not more than two per cent. have failed.

STOVE FOR SMALL GREENHOUSE (J. D.).—It is questionable if the stove that you have would not suit you well enough, if you burned broken coke in it, and had a small chimney of sheet iron from it. No stove without a chimney is safe either for you or the plants, if the latter are tender and growing. A small iron flue, for about 35s. or 40s., would suit your purpose. The chimney may go through the roof, by taking out a square of glass, and substituting a square of sheet iron with a hole in the middle.

RIBBON-BORDER PLANTING (F. J. C.).—Straight or serpentine lines in a ribbon-border are purely a matter of taste. The straight lines are best, when seen from each end, in our opinion. The use of Cerastium in the circular beds, we would have better determined if we had known the size and the arrangement of the beds. For a row of Cerastium it should be planted in lines. If cuttings are put in next month, or this month (say 3 inches apart), they will make a dense row, if looked after, of 3 to 5 inches broad, next season. If to be mixed with some low-growing thing, the Cerastium may be planted much thinner. In your border we would place your plants thus:—Trentham Rose, Perilla, yellow Calceolaria, Scarlet Geranium.

HEATING PITS (C. G.).—For a house or pits the size you speak of, you will want two four-inch pipes for top heat, and the same for bottom heat. One of each might do for the front pipe, but two three-inch pipes, above and below, would be better. We presume you have valves to shut off the front or cooler pit when you choose. We perceive, also, that you mean to heat one of the early pits for Cucumbers by itself, and of course that will require valves. Mr. Fish has no difficulty in heating each range separately, though each range has several divisions, as the air-giving makes the difference in temperature in the different divisions, and valves are dispensed with, which, if numerous, become expensive. If you can feed from the top of the boiler, then a cylinder or tubular boiler would be best for wood, as you could put in pieces nearly the height of the boiler. To do the work you speak of the boiler had better be 16 inches wide, inside measure, at bottom, and 30 inches in depth. The wood, if dry, will burn all the better, and give more heat; the cinders will do for banking up at night. For a saddle-back it should be the above width and length, for wood at least; and the furnace-door should be larger than for coal—say 12 by 15 inches. If a saddle-back is used, and there will be little difference in the result, the boiler should stand as much as three or four bricks above the furnace-bars, so as to give more room for the wood. If you cannot well feed the boiler from the top, the saddle-back will be the easiest managed. If you can so feed the fire, the cylinder will be the easiest managed. In either case, instead of setting the boiler on bricks, though fire ones, it will be better to set the boiler on fire lumps of the suitable height, as bricks are sooner injured by wood than by coals. When you are laying down your pipes, do not stint the quantity. There can be no more false economy than being forced to keep up heat by heating the pipes nearly to boiling-point. The consumption of fuel, and the extra trouble, will soon cost more than the extra piping; and nothing will thrive so well with pipes very hot as when these are rarely warmer than you can put your hand on them. We would like more explicit information as to the ice, mode of ventilating, &c.

ORCHARD-HOUSE PEACHES SPOTTED (*Ramsgate*).—We suspect that the red spots are owing to the attack of insects when the fruit was young—green fly or brown beetle. The other appearance, of imperfect stones, is owing to imperfect fecundation; but if the fruit is of good fair size, that is of less importance. It is caused by keeping the house too close and moist when the trees are in bloom, or just setting their fruit. If carried too far the fruit is sure to drop prematurely.

HEATING VINYERY AND CUCUMBER-HOUSE (A.—A. P.).—If you stop the flow-pipes for bottom heat by valves, you need not trouble yourself about the return-pipes. The simplest plan, as you have not yet done the work, would have been to place the boiler between the Cucumber-house and the vinery, and then take the heating pipes right or left, furnishing the flow of each with a valve. A simpler plan still would be thus to place the boiler, take the flow-pipe into a small cistern in the vinery, 18 inches above the highest heating pipe; let that cistern have three other holes for pipes besides the flow-pipe; let one of these join the flow-pipe in the vinery, a second the flow-pipe for top heat in the Cucumber-house, a third for flow-pipe for bottom heat; and thus, by means of three wooden plugs, you can heat where you like.

VERBENAS (S. C.).—Too faded and destroyed by post-stamper to be distinguished; but even if fresh very few could be recognised from a mass of flowers, the varieties are so numerous, and so approach one another in colour and form.

LINUM FLAVUM TRANSPLANTING IN AUTUMN (E. M.).—You may safely remove this a month or so before severe weather sets in; but, should you be overtaken by the frost before the plants are fairly established, covering them with a little fern, laurel boughs, or other protection, will enable them to live through the winter. Very severe winters sometimes kill this plant, especially in damp situations, but generally it lives through the winter and does well.

BEDDING GERANIUMS (*Stella*).—We have not grown Trentham Scarlet Geranium; but, from what we saw of it, it struck us to be a variety of Tom Thumb, or Frogmore Improved, which beats all other Scarlets at Trentham. This is a peculiarity of many Scarlets, which do extra well in some one place. We have not seen Trentham Scarlet so good anywhere else except at Trentham. Can Mr. Henderson give us a note on the subject? In the generally moist climate there it is stronger-growing than Frogmore Improved in the south. Both it and Boule de Feu are good bedders. The latter has larger trusses of bloom, and throws them high—in some people's opinion rather high—above the foliage. The habit is rather stronger and stouter than Trentham Scarlet. With us the habit of growth is between Tom Thumb and Punch—the latter is very fine with us this dry summer. For a fair-sized bed we would give the preference to Boule de Feu, as compared with Trentham Scarlet, as the flowers are more massive, but both are good. With us neither of them are so strong-growing as Trentham Rose; but they are rather stronger growing than another fine rose, called Rose Superb. This latter is much the same to Trentham Rose as Tom Thumb is to Punch. The trusses of Boule de Feu are brighter and more compact than Punch; the long flower-stalks much stronger, and the habit of the plant more compact. As respects height, we would thus place those you name—Trentham Rose, Boule de Feu, Trentham Scarlet. Until you have tried the last two in your own garden you should grow both.

FLOWER-BED PLANTING (Ignoramus).—When the Geraniums are removed, you may make the bed very gay by planting it with bulbs and early-flowering plants. Plant Snowdrops, Crocuses, Hyacinths, Winter Aconites, and early double and single Tulips, a few patches of each, and to these you may add double Primroses, yellow Alyssum, white Arabis, Armeria, Dilecta spectabilis, Hepaticas, and many others, but as you do not mention the size of the bed, we are not able to advise further. Our "Garden Manual," would suit you.

IVY PROPAGATING (Clare).—The easiest way of propagating Ivy is by layers. If you layer the young shoots in 24-pots in a dry kind of loose poor soil, and fasten them with pegs about half an inch below the surface, placing a stake in each pot and fastening the shoots upright to it, they will be rooted by spring, and may then be detached from the parent. The young shoots, from 6 to 9 inches in length, inserted in poor, light, well-drained soil in a cold frame now and kept moist, will root freely enough, and so they will if inserted in a shady border any time from March to October. Loudon's "Self-instruction for Young Gardeners," will suit you.

BULBS (A Constant Reader).—As you wish to procure bulbs, we may name single and double Snowdrops, which should be potted forthwith. If you have any in your garden these are the sort to succeed with, for dried bulbs will not flower so well, nor force so surely. After potting place them in a cold frame. Of Crocuses, select Bride of Abydos, white; David Rizzio, dark purple; Sir Walter Scott, white and blue striped; New Giant Yellow; Lord Byron, bright blue; Versicolor, striped; Albion, white and blue striped; Large Yellow; La Majestueuse, striped; and Queen Victoria. Full particulars on the cultivation of these and other bulbs will appear in our columns shortly.

PEACHES FOR MARKET—FORCING VINES WITH CAMELLIAS (I. W., Exeter).—We recommended the old Grosse Mignonne, which takes well on account of its size and colour. The Early Grosse Mignonne ripens about three weeks in advance of the Grosse Mignonne, but is a smaller fruit. It would, however, no doubt, sell. The Grosse Mignonne is a good forcing. If the Camellia bloom in January you may commence forcing the Vines shortly afterwards, or in the beginning of February, and the Grapes will be ripe in the end of July or beginning of August. By this process the Camellias will flower about Christmas; but if you commence forcing so as to have the Grapes ripe in June, the Camellia will bloom earlier—perhaps, after one or two years forcing, as early as October or November. To have Camellias bloom at or soon after Christmas the Vines should be allowed to start naturally, and be only assisted with fire heat at the time of setting and maturation of the fruit, which will be perfected in August.

SUBSHRUBS TO SEPARATE FLOWER AND KITCHEN GARDEN (A Recent Subscriber).—As it is a bank we fear it will be dry, or you could not have anything finer than Rhododendrons and American planis. You may, however, have them if the soil is not too dry. In any case you may have Berberis Darwinii and acutifolium, Ulex europea plena, U. hispanica, Viburnum tinus, Persian Lilac, Hollies of sorts, Ribes, Prunus triloba, P. sinensis flore pleno, P. rosea alba, Pernettya angustiolia and mucronata, double Syringa, Pyrus spectabilis flore pleno, Myrica laciiniata, Leycesteria formosa, Forsythia viridissima, Deutzia scabra and gracilis, Desfontainia spinosa, Daphne cneorum and mezereum, Cotoneaster microphylla, Corylus avellana laciiniata and purpurea, double Quince, Cyrtisus secundus, Chimonanthus fragrans, grandiflorus, and luteus, Box of sorts, Cistus ladaniferus, Calycanthus floridus, Ancuba japonica and lati-maculata. We would not have one of these if there were any chance of American plants succeeding. If the soil is moist they will do well unless it rest on or is limestone.

MANETTI STOCKS (S. G.).—Plant them on the level, and keep manure away from them. If any be wanted dug it into the soil, and not in close proximity to the stem. It is not necessary to cover the bud with soil to protect it from frost, but some do so. If covered at all it should be with soil, and not manure or sawdust. If the soil be light, and the stocks budded with tender kinds of Roses, draw a little soil round so as to cover the buds; but if strong a little hay wrapped round them is as good as burying them. It should be removed in dry weather. Wet passing into the union of the bud with the stock is frequently more fatal to the buds than frost. In spring cover the stock with soil to a few inches above the bud, so that the Rose may have a chance of emitting roots as well as the stock. The stock may be stopped or shortened slightly when the budding takes place; but they should not be cut close until the bud has broken, for the portion of the stock above the bud is necessary to draw the sap into it. They may be planted in the places where they are to remain in mild weather from October to April, but the earlier the better. November is best, planting them so that the union with the stock may be 3 inches below the surface.

FORCING VINES IN POTS (A Maidstoneian).—We fear that you will not be able to kill two birds with one stone. If you force the pot Vines as you propose, we would plant them out now, so that they may be established before autumn, and we would not force the pot Vines so early as you name, but defer it until the beginning of March, or at least not start them before the middle of February. We do not see what you will gain by forcing them at all. Newly-planted Vines should be allowed to break naturally, or with a slight assistance from fire heat, and should be grown slowly so as to secure a strong cane, which may be ripened fully in autumn by the application of fire heat. If you commence forcing pot the Vines in January, and plant the young ones at the same time, the strong heat will cause the latter to come weak; and the same would result if they were planted in March, and the pot Vines started in January. As to the sorts, the first two are good but should be planted inside. For Golden Hamburgh we should substitute White Frontignan or Trovérén Frontignan; and instead of White Nice, size being its recommendation, we should have Muscat Hamburgh grafted on the Black Hamburgh. The others will do well.

GARDEN PLANS (S. S. S.).—We never heard of the work. Such plans as those you refer to can only be obtained by applying to a professional garden designer.

STRAWBERRIES PLANTING (G. H. P.).—All your Strawberries would do best on a south aspect. The Black Prince is an early kind and so must have a south aspect. On a north aspect it will be ten to twenty days later than its usual time. Frogmore Late Pine, as a late sort, may be planted on the north aspect, and so may Oscar and La Constante; Carolina superba, however, is a tender sort and requires the best aspect possible, and the same holds true of Myatt's Improved Early.

CENTAUREA CANDIDISSIMA WINTERING (Hanley).—The Centaurea will not do in the same frame with Calceolaria cuttings. To winter it successfully it must be kept in a dry airy part of the greenhouse, and have no more water than is absolutely necessary to keep the foliage healthy. It is a half-hardy plant, the Calceolaria being all but hardy, and not so susceptible of moisture as the Centaurea.

NAMES OF GERANIUM (W. H. B.).—The Geranium you describe is Cybister, one raised by the late Mr. Beaton. You ought to be able to obtain it from any florist.

NAMES OF FRUIT (H. W. C. L.)—1, Red Astrachan; 4, like White Costin; 5, 7, Kerry Pippin; 6, Downton.

NAMES OF PLANTS (Invicta).—Vallota purpurea. The bulb should be about an inch underground. It requires abundance of water during the summer. If in a pot this may then stand in a saucer of water. (Y. P.)—1, Ceterach officinarum; 2, Onoclea sensibilis; 3, Blechnum spicant; 4, Polystichum aculeatum. (J. S.)—1, Polystichum angulare proliferum, one of the several forms of this var.; 2, Athyrium Filix-femina; 3, Polystichum aculeatum lobatum; 4, Polypodium vulgare. (Maple)—1, Impatiens noli-me-tangere; 2, Stachys palustris; 3, S. Betonica; 4, Galeopsis tetrahit. (S. Cappeley).—Polygonum chinensis.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

WANT OF POULTRY SHOWS IN THE SOUTH OF ENGLAND.

It has often been a source of wonder to me as a poultry-fancier, that while so many admirers and exhibitors of fowls live in the south of England, there exists in that district such a remarkable dearth of shows. The contrast in this respect between north and south is very striking, for while we find every little town, and many villages, in Yorkshire and Lancashire boasting its annual show, there are held within the same time not half a dozen exhibitions in the six or eight counties nearest to London. If all the poultry-fanciers lived in the north this would be natural enough; but as it is we find the names of southern exhibitors figuring even at Yorkshire shows. It is obvious enough that those who now send birds some two or three hundred miles for the chance of a prize would, *ceteris paribus*, prefer to support a show within reach of their homes, and whether they could not only send their birds with less risk and at less cost, but also could see their pets wearing their honours by visiting the show in person.

Some one may, perhaps, suggest Birmingham as the great central battle-field at which northern and southern exhibitors can meet on equal terms. But Birmingham after all is not London; and to reach the former place, for those, at least, who live in the southern and eastern counties, is a work of difficulty and expense. Moreover, to the Birmingham Show there are two serious objections: the one being the method of entering for that Show, by which, unless an exhibitor happens to have four pens to send, the sum paid for entrance is unduly high, being for two pens 2s., and for one pen 2s. 6d. The other objection consists in the want of due proportion between the numbers entered and the amount of prize money in some of the more recently introduced breeds.

To return to the south and its shows. I cannot but ask, Why was the Crystal Palace Show given up? In the heart of a suburban, and therefore almost inevitably of a poultry-fancying district, within easy range of the southern counties,

within still more easy reach of London, the Crystal Palace Show seemed under good management to combine all the elements of success. But it is gone, and to encourage its successors is chiefly my wish; and especially to hail with hope the proposed Show at Islington, and to recognise the liberality with which its schedule meets the requirements of the various breeds. It remains for us southern exhibitors to muster in force, and prove that a London show can be, as it ought to be, a success; for surely London is able to do what Halifax and Darlington have done for years.

Let me conclude by throwing out a suggestion, upon the merits of which I shall be glad to have your opinion and that of your correspondents—namely, why not have a poultry association for the home counties, holding an annual show within fifty miles of London at some important town, or, if thought better, in London itself? It might be well to meet one year in Kent, another in Essex, a third in Berkshire, and so on; but at all events to have one annual rallying of the southern poultry exhibitors at a really good show. Surely such an exhibition would draw together from its immediate vicinity a collection of birds inferior to none of those which have made the names of little towns in Yorkshire known to poultry-fanciers throughout the land.—
BRAHMA POOTRA.

KEIGHLEY POULTRY SHOW.

THE twenty-second annual Exhibition of the Keighley Agricultural Society was held at Keighley on Friday, the 2nd inst. The streets of the town were decorated most lavishly, as usual at this annual festival; but the morning proved most unfavourable, heavy showers of rain falling at close intervals, completely drenching many of the fowls and Pigeons. Some exhibitors, more anxious about the comfort of their birds than that of themselves, put into requisition every available covering for their specimens; and, in several cases, by the help of a coat or a rug, a position was obtained in the prize list which, under other circumstances, would probably not have been attained; for it was a task of no ordinary difficulty for the Judges to satisfy themselves as to the merits of the contending pens. Towards midday, however, the weather cleared up, and the show-ground was thronged with visitors, the receipts at the entrance-gates being £360, or £50 more than last year.

In the first class a Silver Cup, value £5 5s., the gift of Mr. Manoah Rhodes, of Bradford, was offered for the best pen of *Game*, either old or young, such pen to contain a cock and two hens, or a cockerel and two pullets. In a severe competition the Cup was awarded to Mr. Elkanah Aykroyd, of Bradford, for a splendid pen of Duckwing chickens, in capital condition, the Judges considering them of most unusual excellence; very seldom, indeed, has such a perfect pen ever been exhibited, and Mr. Aykroyd has reason to be proud of his well-merited success. Miss Beldon exhibited a good pen of Brown Reds; and Mr. Fletcher also showed his Halifax Brown Red Cup cock, badly accompanied, the hens, in addition to not matching, being inferior in other respects. In *Cochins* Buffs were first in both classes, and Whites second. Beyond the prize birds the competition was only poor. *Spanish* were not numerous, but good. Mr. Cannan's commended pen, we think, should have occupied the position of his prize birds. The *Hamburg* classes were well filled, and all contained really good birds; but many of the pens were seen to great disadvantage. Silver *Pheasants* and Golden *Pheasants* were excellent. *Polands* were good, more particularly the White-crested Blacks. *Dorkings* were only a small class, and were much out of condition. Mr. Kell took the first prize in old birds with a good pen. In Red *Game* capital Black Reds were first, and Brown Reds second, in both classes. In Any other variety, *Game* Blacks were first and second in adults; while in chickens only a single pen (Duckwings) was shown. The *Bantam* classes were well filled, Blacks being first in the adult class, and *Game* in that for chickens.

Ducks and *Geese* were fairly represented.

The *Pigeons* were numerous, and many good specimens were exhibited. In *Powters* Blues won all the prizes. In *Carrier* cocks a good Black took first; while the second prize was awarded to a Dun, two good Blacks being commended.

Carrier hens were not a very first-class lot. Almond and Mottled *Tumblers* were not particularly noticeable. In *Owls*, *Turbits*, *Jacobins*, and *Trumpeters* the prize pens were particularly good. *Barbs*, *Fantails*, *Dragons*, *Magpies*, and *Archangels* were average classes. In Any other variety the Halifax judgment was reversed, Mr. Yardley taking first with his wonderful *Satinettes*, *Blue Shields* being second.

The following is the prize list:—

GAME.—Silver Cup, E. Aykroyd, Bradford.
COCHIN-CHINA (Any colour).—First, Miss E. Beldon, Gilstead (Buff). Second, W. Dawson, Hopton, Mirfield (White). *Chickens*.—First, Miss E. Beldon (Buff). Second, W. Dawson (White). Commended, J. Jackson, Ingrow (Buff).

SPANISH (Black).—First and Commended, W. Cannan, Bradford. Second, Miss E. Beldon. *Chickens*.—First, W. Cannan. Second, E. Brown, Sheffield. **CHITTERFRAT**.—First, T. Pickles, Earby. Second, Miss E. Beldon. *Chickens*.—First, R. Longbottom, Bingley. Second, D. Wilson, Salford Fields.

PHEASANT (Golden).—First, J. Newton, Silsden. Second, W. Cannan. Commended, J. Hardwick, Keighley. *Chickens*.—First, W. Driver, Morton Banks. Second, Miss E. Beldon.

HAMBURG (Golden pencilled).—First, J. Gornall, Bradford. Second, S. Smith, Northowram. Commended, Miss E. Beldon. *Chickens*.—First, T. Wilson, Second, T. Pickles. Commended, F. S. Taylor, Manchester.

PHEASANT (Silver).—First and Second, Miss E. Beldon, Commended, W. Cannan. *Chickens*.—First, W. Cannan. Second, Miss E. Beldon. Commended, J. Green and J. Sudgen.

PHEASANT (Black).—First, Miss E. Beldon. Second, W. K. Duxbury, Leeds. *Chickens*.—First, W. Parker, Cottingley. Second, S. Briggs, Hollywell Green. Commended, J. Hargreaves, Skipton.

POLAND (Golden or Silver *Pheasant*).—First, Miss E. Beldon (Silver). Second, W. K. Duxbury (Golden). *Chickens*.—First, D. Wilson. Second, W. Newsholme, Bingley.

DORKING.—First, T. E. Kell, Wetherby. Second, Miss E. Beldon. *Chickens*.—First, E. Leach, Rochdale. Second, T. E. Kell.

GAME (Red).—First, Miss E. Beldon (Black Red). Second, H. Snowden Bradford. Commended, J. Hodgson, Bradford. *Chickens*.—First, T. Dyson, Halifax. Second, H. S. Dodds. Commended, Miss E. Beldon.

GAME (Any other variety).—First, J. Fletcher, Stone Clough (Black). Second, Miss E. Beldon (Black). *Chickens*.—Prize, H. Snowden.

POLAND (White-crested).—First, J. Smith, West Lane. Second, Miss E. Beldon. *Chickens*.—First, H. Carter, Holmfirth. Second, J. Smith.

BANTAMS (Black, White, or Game).—First, Miss E. Beldon. Second, C. Lister, Mirfield. *Chickens*.—First, Miss E. Beldon (Game). Second, C. Lister (Black).

ANY OTHER DISTINCT BREED.—First, C. Walker, Halifax. Second, C. Lister. *Chickens*.—First, H. Lacy, Hebden Bridge. Second, Miss E. Beldon.

DUCKS (Rouen).—First, J. Nelson, Heaton Mersey. Second, S. Briggs.

DUCKS (Aylesbury).—First, F. M. Hindle, Haslingden. Second, E. Leach, Rochdale.

DUCKS (Black Indian).—First, J. R. Jessop, Hull. Second, J. G. Sudgen, Eastwood House.

DUCKLINGS.—First, J. Nelson. Second, E. Leach.

GESEES.—First, E. Baxter, Elslack Hall. Second, W. K. Duxbury.

PIGEONS.—*Pouter* or *Cropper* (Cock).—First, E. Aykroyd. Second, Miss E. Beldon. (Hen).—First, J. Thompson, Bingley. Second, Miss E. Beldon. *Carrer* (Cock).—First, A. Smith, Skipton. Second, J. Firth, jun., Dewsbury. Commended, H. Yardley, Birmingham; S. Briggs. (Hen).—First, J. Firth, jun. Second, Miss E. Beldon. *Tumblers* (Almond).—First, H. Yardley. Second, H. Snowden. (Balds, Beards, or Mottled).—First, H. Yardley. Second, S. Briggs. *Owls*.—First, Miss E. Beldon. Second, H. Yardley. *Trumpeters*.—First, S. Briggs. Second, Miss E. Beldon. *Jacobins*.—First, S. Briggs. Second, Miss E. Beldon. *Leeds*. *Barbs*.—First, J. Firth, jun. See *nd*, S. Briggs. *Dragons*.—First, J. Baxandall, Sutton. Second, J. Rishworth, Eastburn. *Archangels*.—First, S. Briggs. Second, Miss E. Beldon. Second, S. Briggs. *Any other Breed*.—First, H. Yardley. Second, S. Briggs.

RABBITS.—*Long-eared*.—First, S. Stell, Keighley. Second, E. Stead, Keighley. *Any other variety*.—First, R. Emmott, Keighley. Second, D. Lambert, Keighley.

The Judges were Mr. John Douglas, London; and Mr. J. W. Thompson, Southowram, Halifax.

POULTRY EXHIBITION OF THE SPARKENHOE FARMERS' CLUB.

FEW societies can boast of so regular and permanent an amount of annual improvement as the Sparkenhoe Farmer's Club. It appears, from inquiries we made on the spot, that a considerable number of years back a few agriculturists of the district first instituted this Club, as a social means of discussing at its annual meetings any subject that might tend to the general interests of the farmer. Things thus progressed at first slowly, but, as the sequel proves, surely, to the production of one of the best local agricultural exhibitions of which we can boast. Ever ready to promote in every possible way the general benefit and pleasure of their fellow men, the Sparkenhoe Farmers' Club have from time to time added annually some one or other new feature to their customary gathering; and from being held every year

in some fresh locality, its novelty has never shown the most distant symptom of flagging, for, on the contrary, its popularity has invariably become more enlarged.

We cannot resist digressing for an instant to give a brief list of the present year's attractions. First, there was a very extensive and exceedingly good agricultural show of the usual character, with an extensive competition in butter, cheese, &c.; again, a floral and vegetable exhibition, and a public dinner to which ladies were invited—a capital hint, by-the-by, to all similar societies as regards assets; a balloon ascent by Mr. Jackson, the aeronaut of Derby, in his new balloon the "British Queen;" and lastly, though to the female visitors not the least enjoyable, a ball in the evening of very large proportions. To make certainty doubly sure, excursion trains from various districts became the subject of final arrangement, and all things promised a bumper. No amount of foresight, however, can insure the weather; and we are grieved, as faithful reporters, to say it was scarcely possible to conceive anything more unpropitious than was the whole day—rain almost without any cessation. Train after train brought its numerous sight-seers; certain it was, the best "bib and tucker" were not left recumbent in the wardrobes at home; and yet a fatality of wet seemed the irresistible order of the day. We speak positively: had the day proved as fine as the one following, some extra hundreds of pounds admission money would have been readily obtained. In fairness to all, we must say the railway excursion trains were not well managed. The companies had evidently concluded that the Birmingham musical festival, Warwick races, and another event or two of like character held simultaneously would so far contract the numbers of applicants, that very small trains would meet every exigence for transit to the Show. The result was the reverse. Great numbers applied for tickets, and seats could not be obtained; consequently the carriages were crammed, until everywhere the annoyance was complained of. Most of the carriages were, in fact, adult nurseries.

Still, on getting to Ashby-de-la-Zouch, it was a matter of pleasure to see the good humour of the ladies generally, on the unexpected disarrangement of their toilette. The kind host and hostess of "The Royal Hotel," at Ashby, did all humanity could do to put all right again, and however the annoyance might grate within, it is certain it found a very meagre outflow in words. We again express, for the Committee's sake, our regret that fine weather did not give increase to the assets, for they fully deserved it. The poultry tent, as is customary on like occasions, was the great feature of attraction to the Show, and the originators of this meeting are evidently determined that this branch of its popularity shall continue. One of its chief features is the gift of a valuable silver cup to the best three pens of poultry—any varieties at the exhibitor's discretion—shown specially for this premium. This always induces the best of competition, and this year has fully maintained the evident inclination of the public to warmly support the views of its projectors. To show at this time of year three perfect pens from any one yard is a great difficulty, and so it now proved, for the contest for this silver cup was very close indeed, among about four of the many rivals. The best varieties shown were the Black Spanish, Grey Dorkings, Cochins, Golden-spangled Hamburgs, Turkeys, Geese, and Aylesbury Ducks. The "other varieties," both of fowls, and also of aquatic birds, were as much beyond the average.

The Pigeons were also as nice a collection as we have seen for long past, and the Rabbits were, undoubtedly, as rich in good specimens as any amateur could desire.

The tent devoted to the Poultry, Pigeons, and Rabbits, was airy, sufficiently large, and (not less usefully) well ventilated, whilst every possible attention was given to all the specimens confided to the manager's care.

THREE BEST PENS OF POULTRY.—Silver Cup, H. Yardley, Market Hall, Birmingham. Second, G. Bott, Sheepy Magna, Atherstone. Highly Commended, W. T. Everard, Bardon Hill House, Leicester; J. Faulkner, Bretby Farm, Burton-on-Trent; Right Hon. Viscountess Holmesdale, Linton Park, Staplehurst, Kent.

SPANISH.—First, Rt. Hon. Viscountess Holmesdale. Second, M. Brown, Ab-Kettleby, Melton Mowbray (Black). Highly Commended, M. Brown (Black); W. T. Everard. Commended, E. Morley, Sapcote, Hinckley.

DORKING (Coloured).—First, Right Hon. Viscountess Holmesdale. Se-

cond, J. Faulkner. Highly Commended, Countess of Chesterfield, Bretby, Burton-on-Trent; W. T. Everard. Commended R. Trussell, Wouds, Ashby-de-la-Zouch.

DORKING (White).—First, J. Faulkner. Second, W. T. Everard. Commended, T. H. Ashton, New House, Kingsbury, Tamworth.

COCHIN-CHINA.—First, Mrs. Wolferstan, Statfold Hall, Tamworth. Second, Right Hon. Viscountess Holmesdale. Highly Commended, M. Brown (White).

GAME (White, Piles, and Light Colours).—First, H. Warner, The Elms, Loughborough. Second, G. Bott. Commended, H. W. White, Museum Square, Leicester.

GAME (Red, and other Dark Colours).—First, W. Chamberlain, Desford, Leicester. Second, W. T. Everard. Highly Commended, H. Warner; G. Bott.

HAMBURGH (Gold-spangled).—First, W. Draycott, Humberstone, Leicester. Second, H. E. Emberlin, Humberstone, Leicester.

HAMBURGH (Gold-pencilled).—First, T. H. Ashton. Second, W. Harrison, Bagworth Park, Leicester.

HAMBURGH (Silver-spangled).—First and Second, T. H. Ashton.

HAMBURGH (Silver-pencilled).—First, Right Hon. Viscountess Holmesdale. Second withheld.

FOR ANY OTHER DISTINCT BREED.—First and Second, J. Merideth, Grendon, Atherton (Silks and Andalusians). Highly Commended, W. Chamberlain (Ptarmigan).

FREASANTS (Silver).—First, W. Harrison. Second, no competition.

DUCK (White Aylesbury).—First, H. E. Emberlin. Second, M. Brown. Highly Commended, H. E. Emberlin. Commended, H. Warner.

DUCKS (Any other variety).—First, C. B. Lowe, Sheepy Hall, Atherton. Second, Mrs. Wolferstan. Highly Commended, R. Trussell. Commended, J. Choyce, Harris Bridge, Atherton; W. Trussell, Ashby-de-la-Zouch; J. Johnson, Braunstone, Leicester.

GERSE.—First, J. Faulkner. Second, Mrs. Wolferstan. Highly Commended, Mrs. M. E. Worthington, Temple Farm, Hinckley.

TURKEYS.—First, — Coxon, Freeford, Lichfield. Second, J. Johnson. Highly Commended, W. Harrison; J. Johnson. Commended, Mrs. M. E. Worthington.

GUINEA FOWLS.—First, W. Green, Normanton, Ashby-de-la-Zouch. Second, J. Johnson. Highly Commended, J. Johnson.

BANTAMS.—First, Right Hon. Viscountess Holmesdale. Second, H. E. Emberlin. Highly Commended and Commended, H. Warner.

PIGEONS.—*Pouters or Croppers*.—First, H. Yardley. Second, H. E. Emberlin. *Cariers*.—First and Second, H. Yardley. *Tumblers*.—First and Second, H. Yardley. Highly Commended, W. Choyce, jun., Sibson, Atherton. *Fantails*.—First, H. Yardley. Second, W. Draycott. Highly Commended, W. Choyce, jun. *Any other distinct variety*.—First and Second, H. Yardley (Satinettes and Spots). Highly Commended, W. Draycott (Red Turbuts); W. Choyce, jun. (Swallows); H. E. Emberlin (Brunswick); J. Savidge (Archangels).

RABBITS.—*Heaviest Weight*.—First, J. Thompson, Ashby-de-la-Zouch. Second, G. Jones, Birmingham. Highly Commended, J. Thompson. Commended, G. Jones; W. Choyce, jun. *Length of Ear*.—First and Second, J. Read, Coventry. Highly Commended, G. Jones. Commended, J. Thompson; H. Warner; J. N. Dixon, Leicester. *Any other kind*.—First, W. Chamberlain. Second, G. Jones. Highly Commended, H. Warner; G. Jones; W. Chamberlain; J. N. Dixon.

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, Birmingham, was the sole Judge.

BLACK GAME BANTAMS.

THE "WILTSIRE RECTOR" wishes to know the pedigree of Black Bantams. This is a question which I have often asked and I could never obtain a satisfactory answer respecting them; but I can quite agree with his statement, that they are more game than Game.

Having kept Black Game Bantams about six years, I know something of their habits, which resemble those of wild fowl very much. Their habits are most interesting to watch, and can only be known to those who have most carefully attended to them.

I have four hens, a cock, and four chickens, which run along with my other fowls, consisting of Duckwing and Black Game. They agree remarkably well together, which is owing to their being reared in the same yard. In the spring the little hens will take themselves off for about a month, and return with their little families, and only until the hay grass is cut do I discover where they had got to. They generally prefer the shade of a large dock in the middle of the field. In intelligence there is no comparison between these and the ordinary Black Bantam, they being so very much more interesting. They are excellent winter layers, good sitters, and good mothers; their eggs in richness and flavour surpass those of any other fowls, and are of a dark cream colour.

These, in my opinion, are as interesting, profitable, and harmless little pets as can be kept.—J. R.

KENDAL POULTRY SHOW.—We are informed by Mr. G. C. Whitwell, that owing to leaving the neighbourhood he has been obliged to resign the secretaryship.

WORKING SUPERS ON COMMON HIVES.

FORMING STOCKS FROM CONDEMNED BEES.

I AM a young beginner, and am now in possession of two common straw hives; they are weighty, and seem to have plenty of honey. I want none of it this season, but I should like them in a hive on which I could use a super next year, and I beg to ask if they can be shifted into a hive of that kind this autumn, or at what time next spring? bearing in mind that I wish to increase my stock, and to work them without destroying a bee.

My neighbour has four stocks very heavy. He is going to destroy the bees in two of them to take their produce. If he gives me the bees would they survive the winter if driven into an empty hive, and I fed them well, the expense of which I should not mind?—W. H. F.

[Transferring bees and combs to new hives is far too difficult a job to be undertaken by a novice. You had better get a couple of pieces of deal three-quarters of an inch thick and 13 inches square, with a central aperture 3 inches in diameter, and clamped at each end to prevent warping. One of these should be fixed as a platform on the top of each hive by means of mortar in the spring, and an aperture cut with a sharp penknife in the crown of the hive corresponding with the hole in the wood. On this platform a super may be readily worked.

Three or four stocks of condemned bees driven into one hive will fabricate and store combs if liberally fed in the autumn, and may very probably form a good stock next spring.]

COMB-PRUNING.

SINCE I have been a reader of your Journal the subject of comb-pruning has not been much alluded to. In "Bee-keeping for the Many," Payne says hives are to last from fifteen to twenty years, and in another place that he has had one last much longer; but whether he simply means the hive or the colony I am not quite sure, for in giving directions he says that only the outer combs are to be cut out. Taylor, also, in his directions states that combs that are filled with stale pollen or honey, or are mouldy, mildewed, &c., are to be removed.

My own idea of comb-pruning was, that by the occasional removal of combs as they became thickened by breeding, &c., a stock was to be kept in a state of perpetual youth and prosperity; but on thinking the matter over I am at a loss to know what is the really proper method to obtain such a desirable result, for I find it to be the rule that in four or five years a hive becomes worn out, and dies. I have often thought about it, but to-day it was again forcibly brought to my notice by seeing a hive which had swarmed and cast this year, dead, robbed, and empty of all but comb. Removal of the outer combs merely will never keep the hive perpetually new, for these are the combs that are most used by the bees for storing honey, and so are the last to be spoiled by breeding; and to remove a central comb in spring would be, most probably, to take away brood and what little honey had been left for the winter's store. Even to take such a comb out (supposing it to be a bar-hive), would be to chill the brood, at that time so precious. I have thought, how would it be to move, or transpose the combs before removal? for instance, to put the outer comb in the centre of the hive, and the central one in its place for a time before removal. But here again would be the danger of chilling any brood during the transposition. Would "A DEVONSHIRE BEE-KEEPER," and also any other of your bee-keeping readers, tell us their experience in this matter? It is this spoiling of combs which is fatal to Nutt's, and all similar methods of keeping bees.

I commenced bee-keeping in the summer of 1860, by buying one common cottage-hive, or rather a swarm hived into an old cottage-hive. I bought it of an old bee-keeper who lives near me. They have kept bees for at least two generations, if not more; and yet he brought me my swarm on the second day after swarming, and consequently the hive was much weakened by the loss of many bees, and I have only had one swarm from it, and that was last year. This year it did not swarm, as I suppose from the state of the combs. The first year I did not pay much attention to

my bees, although I was very fond of them; but since then, having had many losses of bought hives from the very bad years we have had, I have paid much attention to them, and have experimented a good deal with them in the shape of driving, chloroforming, uniting, fumigating, feeding, &c. In 1861 I had a Nutt's hive stocked for me by a friend with a good swarm in June. In 1862 it swarmed in spite of a bell-glass with a decoy comb, which it would not take to. That year was so bad, that its swarm, which came on the 23rd of June, was of no value, and died, or was chloroformed, and I had some trouble to keep the stock alive: however, it did live (which is more than I can say for four other stocks); but in 1863 it only filled the pavilion, and made a very slight piece of comb in one of the side boxes (no bell-glass). This year it nearly filled one of the end boxes; but when I wanted to remove it the queen obstinately refused to go into the pavilion, and after making several attempts to get the side box away, at last took the pavilion, and have left the queen and her subjects in the end box. I have drained 12 lbs. of honey from the pavilion. The comb was chiefly black; some of the honey also in it was candied, evidently last year's. There was no brood.

I shall be greatly obliged if you will bring the subject of comb-pruning before your readers, and have it thoroughly investigated. If experiments are required to test its value, I shall be glad to make one to try any that are likely to answer, and to send you the result. I have two of Taylor's bar-hives stocked, one with a swarm, last year, and another with my first swarm, this year. It has not been nearly so good a honey season with us this year as it was last.—C. F. G., *Kirton-in-Lindsey*.

P.S.—A full-grown drone, with beautiful pink eyes, was turned out of one of my this-year's swarms. Is this common?

BEES ROBBING—AUTUMNAL UNIONS.

CAN you, or any of your correspondents, inform me how to prevent bees robbing? as I observe my strongest hive, one that has never swarmed, is commencing to attack the other hives. They not only go to one, but try it on two or three. They seem to love plenty of honey, and I have also fed them with the bottle at night; but if anything this appears to make them more vigorous and lively. I have also narrowed the entrances to all the hives, so that they do not get in; but the other bees lose their lives and also the robbers in the defense.

Would you also say if there has been any plan hit upon for autumn joining without fighting? About three weeks since, after taking the queen away, I joined a swarm, giving part to two or three hives, without any fighting at night, but the other day I think they killed every one added to them.—A. B.

[If it be only one hive which offends in this manner, we should sentence it to transportation for a few weeks to a distance of not less than a mile and a half. When brought back at say the latter end of October, you will probably find the work of reformation complete.

We believe the mode of effecting autumnal unions, described by Mr. Woodbury in page 523 of our fifth volume (new series), may generally be relied on to prevent fighting when the stocks to be united are of the same species.]

TRANSPORTING BEES.

I HAVE several times had occasion to send hives to a distance, either by carriers or by rail, and very often I have found that the honey ran out of the comb, and wasted 4 or 5 lbs. In packing I place the bottom of the hive on a circular piece of board and sew pieces of bag round it. Would you inform me, of some method of packing which would prevent the waste above mentioned?—G. C.

[The best mode of packing bees in common hives for transportation either by carrier or by rail, is to invert the hive in a box of suitable size (a tea-chest answers the purpose very well), confining the bees by a piece of cheese cloth securely tied over the hive, which should be kept steady by hay or other suitable material packed tightly round it, and a strip of wood 2 or 3 inches wide fixed across and nailed to the sides

of the box. This latter must be of sufficient depth to leave a space of an inch or more between the hive and the box-cover which, having had some good size holes made in it for ventilation, should be marked "This side up" and nailed down over all.]

UNITING QUEENS TO STOCKS.

THE following observations may, perhaps, interest some of your aparian readers. Having successfully introduced a good many queens to sundry stocks without a single failure by following out the method indicated by "B. & W.", and three queens forwarded to aparian correspondents having also been successfully united to stocks of black bees by pursuing the same course, I was almost inclined to look upon it as infallible. Subsequent experience has, however, led me to modify my opinion, and has compelled me to believe that the introduction of a strange queen is always attended with more or less risk.

In July last I presented a neighbouring bee-keeper with a Ligurian queen, and at the same time detailed to him the course to be pursued in introducing her to his stock of black bees. He gave an account of his proceedings as follows:—

"On Friday evening I received your present, and, after carefully perusing your instructions, set to work, delighted with my task. I soon caught my English queen, and placed her in reserve, allowing the hive to remain queenless till the morning; but five hours after capturing the queen I placed the Italian queen with her subjects over the hole in the top of the hive, covered with the perforated slide. On the following morning, having removed all the Italian workers, I cautiously withdrew the zinc slide, and allowed one bee to ascend; it at once attacked her majesty fiercely, and I removed it.

"Shortly afterwards I admitted another, which seemed better disposed; but in admitting a second, they both set upon her most savagely.

"I found it was of no use at present, so I allowed the queen to remain over the slide till my return in the evening, thinking they would be glad to accept her then. I proceeded as before. The first bee seemed kindly disposed, and my hopes at once revived; but in admitting another, imagine my grief and disappointment, when it instantly attacked her, and before I could kill it inserted its sting in her side, where it remained when I separated them. She lingered until morning. I then presented their old queen to them; she was at once recognised and joyfully welcomed.—G. L.

"I subsequently introduced another Italian queen to this same hive, who was properly received and accepted."

A similar misfortune, however, occurred in my own apiary. "A DEVONSHIRE BEE-KEEPER" kindly presented me with a pure Italian queen. I caught the monarch of one of my own stocks, and after the bees had been queenless for twenty-four hours, inverted the box containing the strange queen over the aperture in the top of the hive, which was covered with a piece of perforated zinc; this seemed to rather quiet the stock, who (not having any brood) were in a great state of agitation; and after they had remained in this state for about five hours I removed all the strange workers, and, placing the queen alone under a tumbler, carefully admitted one bee; it behaved well, a second also conducted itself with becoming decorum, but a third at once got upon the back of the queen, and almost instantly inflicted a mortal wound. A spare queen from one of my nucleus-boxes was accepted with but little trouble the following day.—J. E. B.

FOUL BROOD.

WHEN the "DEVONSHIRE BEE-KEEPER" published the doleful account of his disastrous experience of foul brood last year, I confess I thought he had drawn largely upon his imagination, and magnified a very trifling evil into one of vast dimensions in order to enliven the Journal with a little variety and astonish the aparian world.

With Mr. Lowe I could not divine how a malady so malignant and infectious as had been described, could frequently, or only occasionally, play such havoc in our hives

without attracting the serious attention of our keenest English observers.

If Mr. Woodbury had been given to romancing, or if he had stood alone and no witness had appeared to confirm his testimony, it is probable that the evil which he had described would have been regarded by many people as entirely of his own creating. It was an evil which I had not previously seen or noticed, and I quite sympathised with the view of Mr. Lowe, when he ascribed its origin to "chill."

In this opinion I was somewhat confirmed on the 26th of October last, by finding on that day a hive, which I had previously set aside as my best stock for winter, in anything but a prosperous condition. It was a common cottage straw hive, had swarmed twice in the July previous, and contained at least two stones of honey. On turning it bottom upwards I found the bees reduced to a mere handful, and the whole brood-comb to the extent of 230 superficial square inches, sealed over. It having a very suspicious appearance I immediately cut out the comb, and on probing the cells found in every one which I pierced either dark dried matter, a putrid viscous liquid, or defunct rotting nymphs. The smell from the comb was peculiar. Here, then, I at once concluded, is the much-talked-of foul brood which occupies such a prominent position in the Journal.

Lest there should be some mistake regarding it, I determined to send a specimen to Mr. Woodbury for his opinion. Accordingly I despatched, per post, a few inches of the affected comb in a box, and in reply to my inquiries received for answer in one letter, "I have not the least doubt of its containing foul brood;" and in another "I am bound to say differed not in the least (so far as I could discover), from that in my own apiary." This identification of an affection which I had found in a bell-shaped cottage-hive with the true foul-brood disease was just what I desiderated, for it occurred to me that I could prove to Mr. Woodbury's entire satisfaction that the evil now manifested was simply the result of "chill." The hive in question had not been moved from its stand for twelve months, and in the casts which it sent off on the 3rd and 15th of July, there was no disease whatever, as was proved by careful inspection; but when it threw its second swarm on the 15th, the population would be greatly reduced, whilst much of the brood would be still unhatched. At that time the days were warm, but the nights were cold, and on the night of the 18th, as is recorded in the Journal, there was 5° of frost—a temperature which we believe was never before registered in July. Here, then, I said to Mr. Woodbury, is a cause sufficient to account for all the evil which I have found, and scarcely a doubt on the subject remained when I reflected that infection had not been conveyed from the diseased parent to its offspring, which appeared to be in as healthy a condition as possible. Of this I made myself quite certain, as will appear from what I have to say regarding the first cast of the 3rd, which had been lodged in an eight-frame Huber hive. From this eldest offshoot of the diseased hive, which for brevity I shall designate Huber, four whole combs were cut out and the upper halves of two others. The bees were then driven out and a careful examination made of the two half and two whole combs left, but in no part of the hive was a single foul cell found, so I returned the bees to their almost emptied dwelling. Why should this hive be in such a healthy flourishing condition, when its parent was dwindling away under the fell power of a malignant and most infectious disease? This was a question, on the supposition that Mr. Woodbury had correctly described the evil, which I could not answer; and when Mr. Lowe put forth his able statement at the beginning of the year, I could not help thinking truth might yet be on his side, notwithstanding the vast mass of evidence which had been brought forward in support of Mr. Woodbury's views. But I was open to conviction, and I resolved to test the infectious character of the complaint which had been pronounced identical with Mr. Woodbury's foul brood.

For this purpose I selected for experiment a healthy cottage straw hive, and the Huber-hive just mentioned, containing only two half and two whole combs. These I fed most liberally with honey taken from the diseased hive, and by the 14th of April of this year the comparatively empty Huber contained brood in all stages, which so far as I could judge were quite healthy. On that day, also, it commenced

comb-building, and by the end of May the two half-combs that had been cut out were replaced by new ones, whilst the end of June saw the completion of four others in the place that had been vacant during winter.

The new combs were made in succession, and I daily witnessed through the glass the queen depositing eggs in them; but I was careful not to open the frames lest the brood should be chilled. The first circumstance that attracted my attention was the frequent disappearance of larvæ from the cells, which, however, were not allowed to remain long empty. As soon as they were cleaned out they were again replenished with eggs by the queen. Their disappearances were distinctly detected in a comb adjoining the glass, which was made on the 18th of May. Still all seemed to progress favourably till the 26th of June, when I was a little surprised by seeing amongst the sealed brood several cells with flattened or perforated covers. On opening the glass and thrusting the point of my penknife into them, I found, in all of the above character, unmistakeable foul brood, dark slimy matter, identical with what I had seen in the affected hive in October. But yet the bees continued to increase in numbers, and by the end of the first week of July, Huber was fully replenished with comb and so populous as to begin to cluster outside. Being the height of the clover honey harvest I daily expected it to swarm, but in this I was disappointed, and on the 23rd of July the desired result still seemed remote. I, therefore, removed the queen and a portion of the bees from it to a unicomb-hive for the purpose of observation, leaving the remainder to raise a new queen from the eggs and larvæ, of which they had an abundant supply; but not even one queen could be reared. I therefore ejected the whole of the bees with a view to a careful inspection of all the combs. As I suspected, there were foul cells in every comb; even amongst the stored sealed honey there were sealed cells filled with putrid matter rendering the comb quite unfit for the table, and consequently showing how improper it would be to give the honey to healthy bees. The queen and the portion of bees which I removed to a unicomb for observation at once commenced their labours, and by July 30th a large portion of comb was furnished with eggs and larvæ, which induced me to remove the queen that they might attempt to raise another. The foundations of two royal cells were laid, but only one succeeded, the larvæ in the other perished on the eve of being sealed-up.

In this unicomb I had the opportunity of witnessing the disappearance of a few worker larvæ, and now I imagine that the first visible symptoms of foul-brood disease in new comb is the finding empty cells, or cells with eggs newly deposited in them, interspersed among the recently sealed-up brood. The sealed brood in the unicomb generally matured; but on the 21st of August, three weeks from the period of the old queen's removal, and when the last of the young bees should have left their cells, a few cells still remained sealed. Some of them I opened-up and I found enclosed, as I had in the Huber, dark putrid matter. Others I left undisturbed to see what the bees would do with them, but to-day (September 2nd), these sealed cells have scarcely changed their appearance, the covers are not perforated, and so little are they flattened that simply looking at them I would say they contained healthy brood, did I not know it to be otherwise.

So much for Huber. Let us now return to the common cottage straw hive which I selected along with Huber for experiment, and which was also but not so liberally fed with honey taken from the first diseased hive. Unlike Huber it threw two swarms, one on July 4th, and another on the 12th. Shortly after sending out its last swarm I took it up and found, that out of seven queen cells that had been formed two had come to perfection, the others had proved abortive, or were still sealed and contained black-coloured putrid matter. There was foul brood in every comb, and as in Huber, there were also interspersed amongst the stored honey foul cells full of putridity. The idea presented itself to me that weather influences might possibly have something to do with the state in which I found my hives, seeing that June had been cold and wet, and that on the 30th and 31st of May there had been several degrees of frost. I was most unwilling to admit, if I could find another sufficient cause, that disease had been induced by feeding

with infected honey. To determine this point I broke up several cottage-hives corresponding to my experimental one, at one, two, and three miles distance, and which had also swarmed about the same time as it; but in none of them did I find a single foul cell.

Finally, on the 11th of August, I put a very strong swarm with a prolific queen into an empty skep, and fed it with the infected honey taken from Huber and the broken-up cottage-hive. On the 22nd I broke it up, and found what I now regard as a sure symptom of disease, empty cells amongst the recently sealed-up larvæ, in which, of course, there had once been larvæ, but which had died and been removed by the bees. When the fed diseased straw hive threw its first swarm on July 4th, the flowers were full of honey, and as every bee would be filled with honey taken directly from the flowers, no infection would be carried along with them. This was the case, there was not the vestige of disease in the first cast. But in the second cast I found the brood comb regularly sealed, and, consequently, I destroyed it without waiting for the full development of the disease.

The conclusions, therefore, to which I have been constrained to come from these experiments and others not related are—1. Foul brood is a real disease and not caused by the brood getting chilled. 2. It is infectious.

Mr. Woodbury appears to have told the simple truth respecting it, and I verily believe that if I had not been careful to employ remedial measures, it would in a short time have assumed the same virulent and malignant type in my apiary that it did in his. The disease may exist from year to year in an apiary where natural swarming only is allowed, by feeding stocks with refuse honey from taken hives.

I shall be very glad to learn, whether Mr. Lowe has seen anything in his apiary this season to modify his former opinions on this subject.—R. S.

DOBNEY'S TEA GARDENS, ISLINGTON.

NEAR to the "Three Hats," was a place called "Dobney's Tea Gardens," kept by a Mrs. Ann Dobney, where there was a rival equestrian named Prince. These latter gardens occupied the ground between White Lion Street and Winchester Place, and were established as far back as 1728. In 1771 the house was shortly taken for a boarding-school, but it was soon changed to its original place of amusement; for in 1772 Daniel Wildman exhibited his bees here. This was the advertisement:

"June 20, 1772.

"EXHIBITION OF BEES ON HORSEBACK."

"At the 'Jubilee Gardens,' Islington (late Dobney's) this and every evening until further notice (wet evenings excepted).
